Future of Quantum Computing:

The future of quantum computing is here. As quantum computing develops quickly, it will have a major impact on the future of computing. A quantum computer could transform the way we think about computing, increasing processing speeds exponentially and granting access to previously inaccessible data.

Unlike classical computing, which uses bits to represent data and perform operations, quantum computing uses qubits (quantum bits), which can exist in multiple states that are probabilistically determined, known as superposition. This will allow quantum computers to perform certain types of calculations much faster than classical computers.

While it is still an emerging technology, there have been significant advancements in the field in recent years. Quantum computing is a rapidly developing field, and its future is full of exciting possibilities. Several potential directions for quantum computing in the future are listed below:

IMPROVED HARDWARE:

Developing hardware that can reliably perform quantum computations is one of the main challenges in quantum computing. In order to mitigate the effects of noise and decoherence, researchers are developing better quantum processors and improving error correction techniques.

APPLICATIONS IN CHEMISTRY & MATERIALS SCIENCE:

By simulating complex chemical reactions and interactions that are difficult or impossible to model with classical computers, quantum computing may be able to greatly accelerate the discovery of new materials and drugs.

ADVANCEMENTS IN CRYPTOGRAPHY:

Quantum computing could potentially break many of the encryption algorithms used to secure sensitive information today. However, researchers are also working on developing new quantum-safe encryption methods that would be resistant to attacks by quantum computers.

OPTIMIZATION & MACHINE LEARNING:

Quantum computing could be used to solve optimization problems that are intractable for classical computers, such as those encountered in logistics and supply chain management. Quantum machine learning could also offer significant improvements in data analysis and pattern recognition.

HYBRID CLASSICAL-QUANTUM COMPUTING:

Many applications may require a combination of classical and quantum computing to achieve the best results. Researchers are developing methods for integrating classical and quantum algorithms to take advantage of the strengths of each approach.

Overall, the future of quantum computing is bright, with the potential to revolutionize fields ranging from medicine to finance to cybersecurity. Even so, quantum computing may not be widely accessible and practical for real-world applications for several years.

Pros of Quantum Computing:

The pros of quantum computing encompass a range of potential benefits and advantages that this revolutionary technology could offer:

Exponential Speedup:

Quantum computers have the potential to solve certain problems exponentially faster than classical computers. Tasks that are currently intractable due to their complexity could be tackled efficiently with quantum algorithms, leading to significant advancements in various fields such as cryptography, optimization, and drug discovery.

Enhanced Data Processing:

Quantum computing's ability to process vast amounts of data simultaneously could revolutionize data-intensive tasks, including data analysis, machine learning, and simulations. This could lead to faster insights and discoveries, particularly in areas like weather forecasting, financial modeling, and material science.

Improved Cryptography:

While quantum computing poses a threat to classical cryptographic methods, it also offers opportunities for developing quantum-resistant cryptographic algorithms. Quantum cryptography techniques, such as quantum key distribution, could provide unprecedented levels of security for communication channels, safeguarding sensitive data against cyber threats.

Drug Discovery and Material Science:

Quantum computers could accelerate the process of drug discovery by simulating molecular interactions and predicting the properties of new compounds with unparalleled precision. Similarly, they could revolutionize material science by simulating the behaviour of complex materials and facilitating the design of novel materials with tailored properties.

Optimization and Logistics:

Quantum algorithms have the potential to optimize complex systems and solve combinatorial optimization problems more efficiently than classical algorithms. This could lead to improvements in supply chain management, logistics, and resource allocation, resulting in cost savings and increased efficiency.

Machine Learning and AI:

Quantum computing could enhance machine learning algorithms by enabling faster training of models and more accurate predictions. Quantum machine learning techniques could unlock new possibilities for pattern recognition, natural language processing, and other AI applications.

Financial Modelling and Portfolio Optimization:

Quantum computing could revolutionize financial modelling by enabling more accurate risk assessments, portfolio optimizations, and trading strategies. This could lead to better investment decisions, reduced market volatility, and improved financial stability.

Climate Modeling and Energy Optimization:

Quantum computers could contribute to tackling climate change by simulating complex climate models more accurately and efficiently. Additionally, they could optimize energy systems, leading to more sustainable energy production and distribution solutions.

Overall, the potential benefits of quantum computing are vast and could reshape various industries and scientific disciplines. However, realizing these benefits requires overcoming significant technical challenges and advancing the state-of-the-art in quantum hardware, algorithms, and software.

Challenges in Quantum Computing:

Decoherence :

Decoherence is the interactions a qubit has with its environment which causes disturbances and collapse superposition. Decoherence also explains how quantum mechanics is the basis of classical mechanics. Decoherence ends the quantum state, and the traditional signs of atoms and larger things function as expected. Decoherence in quantum systems, is the irreversible process by which a pure state becomes a mixed state.

[Decoherence can be viewed as the loss of information from a system into the environment , since every system is loosely coupled with the energetic state of its surroundings]8. Viewed in isolation, the system's dynamics are non-unitary.

Error Correction:

[Qubits, the building block of a quantum computer are extremely sensitive to the environment disturbances' slightest change in temperature, or any interactions with surrounding molecules could cause a qubit to lose its information]2.

Output Observance:

Retrieving output data after a quantum calculation is complete risks corrupting the data. Developments such as database search algorithms that rely on the special wave shape of the probability curve in quantum computers can avoid this issue.

Qubit Noise:

Quantum noise is a formidable adversary in the quest for functional quantum computers. Unlike its classical counterpart, which typically introduces random errors into a signal, quantum noise disrupts quantum systems in more intricate and detrimental ways. This interference, stemming from various sources such as thermal fluctuations, electromagnetic interference, and imperfections in quantum gates, poses a significant hurdle in quantum computation. To tackle this challenge, researchers are exploring various avenues, including improving qubit isolation, refining control techniques, and implementing quantum error correction codes. The ongoing endeavor to understand quantum noise and develop methods to mitigate its effects is crucial for the advancement of quantum computing. Some algorithms, like the Quantum Approximate Optimization Algorithm (QAOA), are designed with resilience to noise, making them promising candidates for near-term quantum devices.

Data Security:

Securing data in the realm of quantum computing stands as a paramount challenge, spurred by the unparalleled capabilities of quantum systems that can

potentially undermine classical cryptographic safeguards. While the dawn of quantum computing promises revolutionary breakthroughs in problem-solving, its capability to execute certain calculations at exponential speeds compared to classical computers poses a formidable threat to conventional cryptographic methods.

Scalability:

One of the main challenges of quantum computing is scalability, or the ability to increase the number and quality of qubits in a system without compromising their performance and reliability. Scalability is crucial for achieving quantum advantage, or the point where quantum computers can outperform classical computers for certain tasks.

Prevention of Challenges in Quantum Computing:

Error Correction:

[Quantum error correction is a scheme for protecting information from noise in device. It also used to reduce the errors occur in the decoherence aslo. Fault-tolerance builds on this]7. Fault-tolerant quantum computers also prevent errors from spreading during the error correction process or during a computation.

Noise re-silient algorithm:

A noise-resilient algorithm is designed to operate effectively even in the presence of noise, errors, or uncertainties in the input data or the computational environment. In the context of quantum computing, where noise and errors are inherent due to decoherence and other sources, noise-resilient algorithms are essential for achieving reliable quantum computation.

Securing Quantum Computing itself:

Quantum computing also needs its own security measures. Quantum error correction codes are used to protect quantum information from errors introduced by decoherence and other noise sources. Techniques such as quantum state verification and quantum secure multi-party computation are being developed to ensure the integrity and confidentiality of quantum computations.

Quantum Interconnects:

Efficiently connecting a large number of qubits is essential for scalability. This involves creating a network of qubits that can interact with each other in a controlled manner to perform quantum operations.

Cooling Systems:

Quantum computers operate at extremely low temperatures. As the system scales up, the cooling requirements become more demanding to maintain the necessary operating conditions for the qubits.

Application of Quantum Computing:

Cryptography and Cybersecurity:

Quantum computers could break traditional cryptographic methods like RSA and ECC, but they could also enable the development of quantum-resistant cryptographic algorithms and quantum key distribution (QKD) protocols for secure communication channels.

Optimization and Operations Research:

Quantum algorithms can solve complex optimization problems more efficiently than classical algorithms. This includes tasks like route optimization, supply chain management, and portfolio optimization in finance.

Quantum Computing in Drug Testing:

Quantum computer could be used to optimize drug design and the drug testing process. Quantum computers can also perform simulations and could compute accurate simulations of a new drug on virtual human subjects, only within a few

hours. This would save drug companies money and time, as well as remove the number of test subjects for a study, be it animal or human test subjects. This process has already been tried by the company InSilico Medicine, which was able to develop a new drug candidate in 46 days using a simulated algorithm. Quantum computers have many other uses when it comes to healthcare. For those having radiation therapy, a quantum computer could simulate the least harmful treatment that would best target only the cancerous tissue and not healthy tissue. Because of its fast and efficient computing power, quantum computing could also be able to sequence or analyze whole human genomes much faster than a regular computer. This faster genetic analysis could lead to a tidal wave of consequences, from better genetic screenings for genetic diseases to more accurate drug screens. Quantum computing additionally offers more secure medical data through quantum data encryption (which we'll cover in another article). This data encryption could make medical data more secure and protected from hackers or ransomware.

Machine Learning and Artificial Intelligence:

Quantum computing could enhance machine learning algorithms by enabling faster training of models and more accurate predictions. Quantum machine learning techniques have the potential to revolutionize pattern recognition, natural language processing, and other AI applications.

Financial Modelling and Risk Analysis:

Quantum computing can optimize financial models for risk assessment, portfolio optimization, and trading strategies, leading to better investment decisions and reduced market volatility.

Weather Forecasting and Climate Modelling:

Quantum computers can simulate complex weather and climate models more accurately and efficiently, leading to improved weather forecasts, climate predictions, and better understanding of climate change dynamics.

CONCLUSION

Quantum computing blends theoretical principles with technological strides, presenting vast potential alongside daunting obstacles. From its inception in quantum mechanics to recent breakthroughs, it embodies a relentless pursuit of computational prowess, leveraging superposition and entanglement for exponential speedups. Yet, challenges like decoherence and quantum noise impede its progress, demanding ongoing research in error correction and data security. Despite hurdles, its applications in cryptography, optimization, and beyond promise transformative impact, requiring collaboration and innovation to fully unlock its benefits. [Today's quantum computers are nowhere near large enough to execute Shor's algorithm in a practical setting, and the expert consensus is that these cryptanalytically relevant quantum computers (CRQCs) will not be developed until at least the 2030s]¹⁷. In summary, quantum computing melds theory and technology to offer immense promise amidst significant challenges. Rooted in quantum mechanics, it seeks computational supremacy through principles like superposition and entanglement. Yet, hurdles such as decoherence and quantum noise persist, necessitating research in error correction and data security. Despite obstacles, its applications in cryptography, optimization, and more hold transformative potential, demanding collaboration and innovation for realization.

ABSTRACT

The Internet of Things (IoT) represents a paradigm shift in the realm of technology, facilitating the interconnection of everyday objects in a smart environment. As we transition from conventional web structures to a more pervasive computing landscape, the need for intuitive information access becomes paramount. Mark Weiser's concept of ubiquitous computing heralds a new era where objects, augmented with sensors and computational capabilities, seamlessly interact in what he termed a "smart environment." The inception of IoT, credited to Kevin Ashton, envisages a world where mundane objects are imbued with connectivity, laying the foundation for a comprehensive Internet of Everything (IoE). This paper explores the evolution and implications of IoT, addressing its conceptual underpinnings, technological advancements, and transformative potential across various industries.

INTRODUCTION

The rapid evolution of Internet technology has ushered in a revolutionary era characterized by the interconnectedness of physical objects, which experts refer to as the Internet of Things (IoT)[10]. This paradigm shift goes beyond traditional web architecture, ushering in a new era of ubiquitous computing where everyday objects become nodes in an interconnected network. Originating from visionary concepts articulated by luminaries such as Mark Weiser and Kevin Ashton, IoT promises to revolutionize how people interact with their environment by enabling seamless communication across various organizations. Karimi and Atkinson claimed, expanding communication networks to include physical objects will further

accelerate the number of connected devices, as well as the amount of information that can be shared through the Internet[1]. As IoT permeates diverse industries, its transformative potential becomes increasingly evident, with connectivity becoming ubiquitous and the boundaries between the physical and digital realms becoming blurred. This article delves into the complexities of IoT, exploring its conceptual foundations, technological requirements, and its numerous implications for society as a whole.

The Internet Of Things:

In the past decade, Internet technology has transformed human communication at an unprecedented rate and speed. Further evolution is expected to enable interoperability between various objects in what experts call a smart environment.

As we move from WWW (web of static pages) to Web2 (web of social networks) to Web3 (ubiquitous computing or web of things), the need for on-demand information using complex intuitive questions increases dramatically. This era can be called the post-computer era, where smartphones and similar devices change our environment and how "things" (including people) interact. Objects in the new environment are interactive and informative.

IERC definition of IoT [4]

Mark Weiser (father of Ubiquitous Computing) defined the new ecosystem as a "smart environment" in the physical world, rich in sensors, actuators, displays and computing elements and invisible, seamlessly connected and connected to everyday objects. network". As mentioned above, Gubbi et al. argued that the growth of ubiquitous computing is driven by cloud computing and IoT[8]. IoT as a concept is credited to Kevin Ashton, who argued that "adding RFID and other sensors to everyday objects will create the Internet of Things and lay the foundation for a new era of machine adoption." Since then, the idea has been adopted in the research and industrial ecosystem. Roman et al. Proving that an IoT device will have a web-based, addressable and readable peer as a single object, IoT opens up communication channels with other entities, providing and receiving services anytime, anywhere and anywhere; road In that sense, most "things" (for example, people, pets, livestock, computers, books, cars, lifestyle devices, and food) will be on the Internet in some form, leading to the development of the Internet of Everything (IoE) .) to display a large number of features. In 2005, the International Telecommunication Union (ITU) proposed the concept of the Internet of Things in the ITU Network Reports 2005[11]. The report described the IoT era as an era in which cars will automatically warn the driver when he makes a mistake; if the baggage carrier can remind you of something you forgot to take; washing machine colour and temperature requirements etc. will

report. The worldwide IoT security market is expected to expand at a Compound Annual Growth Rate of 33.7% from 2018 to 2023 due to the increasing number of cyber attacks on IoT devices, growing IoT security regulations, and rising security concerns[5]. The IoT European Research Group (IERC) defines IoT as an integrated part of the future Internet with the following characteristics: Since then, several studies have looked at different aspects of IoT. For example, Roman et al. provide a clear analysis of the characteristics and security challenges of the Internet of Things from the point of view of distributed systems. Among the issues discussed are identity and authentication, access control, protocols, fault tolerance, trust and governance.

Need Of Cyber Security In IOT

According to Roman et al. [3], one key challenge which must be overcome in order to push IoT into the real world is security. Security challenges relating to IoT line information Systems (IS) security objectives (SO) which are confidentiality, integrity, and data availability[2]. The Centre for Internet Security (CIS) publishes Consensus Audit Guidelines (CAG) consisting of 20 key actions, which are called critical security controls (CSC), that organizations should implement to prevent or mitigate cyber attacks[6]. The following bar graph(Fig 1) shows a steep rise in the rate of attacks in the first half of 2023 compared to the second half. The y-axis shows the increase in attack rates, while the x-axis shows two time periods, January to June (Jan-Jun) and July to December (Jul-Dec). According to the graph, the rate of attacks started at 1% in the first half of 2023 and increased significantly to 90% by the second half of the year.

Fig 1: Rate of Attacks

Lack of Physical Barriers:

Implement physical security measures such as locked cabinets and restricted access areas for critical devices.

Insecure or Outdated Components:

Utilize well-established hardware and software components with a history of security updates.

Prioritize devices that receive regular security patches and updates from the manufacturer.

Weak or Hard-Coded Passwords:

Enforce the creation of strong, unique passwords for all devices.

Implement multi-factor authentication (MFA) whenever possible.

Avoid using default passwords and disable remote access features when not required.

Insecure Data Encryption and Transfer:

Encrypt data at rest and in transit using robust encryption algorithms.

Utilize secure data transfer protocols like HTTPS.

Insecure Network Services:

Segment your network to isolate IoT devices from critical systems.

Disable unnecessary network services on IoT devices.

Keep network firmware updated with the latest security patches.

Lack of Privacy Protection:

Implement data minimization practices, collecting only essential data for the device's function.

Provide users with clear and transparent privacy policies outlining data collection and usage practices.

Allow users to control their data and opt out of data collection where possible.

Lack of Secure Update System:

Choose devices with a guaranteed update lifecycle and secure update mechanisms.

Prioritize deploying devices that allow for automatic security updates.

Insufficient Knowledge:

Provide security awareness training for personnel involved in the design, deployment, and use of IoT devices.

Foster a culture of security within the organization.

Unclear Job Roles and Insufficient Resources:

Clearly define roles and responsibilities for IoT security within the organization.

Allocate adequate resources for securing IoT devices, including budget and personnel.

Prioritization of Productivity over Security:

Integrate security considerations into the entire development lifecycle of IoT devices.

Conduct security testing before deploying devices.

Legacy Liabilities:

Develop a plan to phase out insecure legacy devices as soon as possible.

Isolate legacy devices from the rest of the network if they cannot be updated or replaced.

Environmental IoT Challenges:

Use ruggedized devices designed for harsh environments.

Develop environmental security protocols specific to the deployment conditions.

Most Targeted Industries By IOT Threats:

Fig 2 : Targeted industries by Hackers

According to the above bar graph(fig 2) the healthcare industry stands out as a prime target, accounting for roughly X healthcare institutions (40% based on your data) falling victim to such attacks in 2023. This vulnerability likely stems from the sensitive nature of patient data and medical devices they handle, making them highly attractive to cybercriminals .Coming in a close second is the automotive industry, with approximately Y connected cars (30% based on your data) compromised globally in the same year. The rising number of internet-connected vehicles creates a worrying trend, as attackers could potentially hack and remotely control them. Retail businesses worldwide are not spared either, with an estimated Z incidents (25% based on your data) reported in 2023. The vast amount of customer data, particularly credit card information, stored by retailers makes them a target for cybercriminals seeking financial gain. While the healthcare, automotive, and retail industries face the brunt of these attacks, other sectors aren't entirely immune. The study suggests that roughly A agricultural operations (2% based on your data) and B units of municipal infrastructure (3% based on your data) globally were also impacted in 2023. While the numbers appear lower, it highlights the growing pervasiveness of IoT threats across diverse sectors[12].

Hardware Security Solutions:

Unauthorized Access Prevention: Implement hardware-based security measures to restrict unauthorized access to IoT devices and data. This may involve utilizing firewalls, intrusion detection systems, and access control lists.

Data Encryption: Utilize hardware-based encryption to protect data both at rest and in transit. This ensures that sensitive information remains safeguarded from unauthorized access, even if intercepted.

Vulnerability Assessment: Employ hardware-based vulnerability assessment tools to identify and rectify vulnerabilities in IoT devices and networks. This proactive approach aids in preventing security breaches and other related incidents.

Threat Detection and Response: Deploy hardware-based threat detection and response systems to continually monitor for security threats and promptly respond to incidents. This proactive stance helps mitigate the impact of security breaches and other incidents.

Compliance Support: Utilize hardware-based security measures to ensure compliance with industry standards and regulations pertaining to IoT security. This aids businesses in avoiding fines and penalties associated with non-compliance.

Protect sensitive data: IoT devices often collect and store sensitive data. IoT device security solutions can help protect this data from unauthorized access by encrypting it at rest and in transit.

Data breach prevention: IoT devices are vulnerable to cyber attacks. IoT device security solutions can prevent data breaches by detecting and blocking unauthorized access to IoT devices.

Ensure regulatory compliance: Many businesses must comply with regulations that require them to maintain the security of their data. IoT device security solutions can help businesses meet these regulations.

Improve operational efficiency: Security breaches can cause downtime and disrupt business processes. IoT device security solutions can help improve business efficiency by reducing downtime and disruption caused by security breaches.

Protecting Brand Reputation: A data breach or other security incident can damage a company's brand reputation. IoT device security solutions can help businesses prevent security breaches and protect brand reputation.

Real-time Threats:

Brute force attack:

A brute force attack is an unauthorized attempt to access a vehicle's systems by systematically trying different passwords or codes. For instance, it can be used to unlock or start the vehicle without permission, leading to theft or misuse. Such attacks target vehicle and their network systems and pose a risk to manufacturers in the form of taking the control of the total vehicle, dealers and owners, potentially resulting in firmware issues, data breaches or theft. Strong automotive cyber security measures are essential for brands to prevent this potential loss.

Abuse of electric vehicle (EV) charging stations.

Electric vehicle charging stations are an important part of the booming EV ecosystem. However, digital infrastructure and charging station equipment around electric vehicles may be vulnerable. A hacker could exploit this disadvantage by taking control of the device, spoofing it, using its data, or taking down the charging station. Therefore, making sure the safety of the EV charging infrastructure is important and structured for the reliability and success of safer mobility[13]. Also the industries that manufacture the EV vehicles should take responsibility in tracking down the security of the vehicle.

CONCLUSION

The Internet of Things (IoT) represents a major change in our technological landscape, providing a future where ordinary objects will effortlessly communicate

in smart networks. Inspired by pioneers like Mark Weiser and Kevin Ashton, the potential of the Internet continues to expand. Our research delves into the fundamental concepts, complex technology architectures, and profound impact of the Internet of Things on industry. From the evolution of the web framework to Ashton's IoT vision, our journey includes exploring the connectivity and intelligence that surrounds us. Beyond the promise of IoT, strong cybersecurity measures are needed. The inherent vulnerabilities in connected devices pose a major challenge, especially in industries such as healthcare, automotive and retail[7]. Combating cyber threats requires a holistic approach to data protection, breach and compliance. Adopting a device-centric security solution offers proactive protection against unauthorized access, data breaches, and operational errors. By incorporating encryption, vulnerability assessment, threat detection, and enforcement mechanisms into IoT infrastructure, businesses can strengthen their security posture, protect sensitive data, and maintain brand integrity and business efficiency. As we face the interconnectedness of the future, stakeholders must take advantage of the transformative potential of the Necessary Internet while prioritizing security issues. By working together, we can utilize the productive power of the Internet to revolutionize the industry, improve human welfare, and usher in the era of innovation and connectivity

AN IOT DEVICE COMPATIBILITY TESTING TOOL

Ranjith.B, Madhan kumar.M, Prasanth.S, Sabhareesh.S.

ABSTRACT

As the Internet of Things (IoT) continues to expand, ensuring the seamless interaction and compatibility among diverse IoT devices becomes increasingly crucial. This paper introduces a novel IoT Device Compatibility Testing Tool aimed at addressing this challenge. The tool provides a systematic approach to assess the compatibility of IoT devices across various protocols, standards, and platforms. Leveraging automated testing procedures and comprehensive test suites, it enables efficient identification of compatibility issues and facilitates the validation of interoperability between devices. The tool's intuitive interface and customizable testing parameters empower developers and testers to conduct thorough compatibility assessments with ease. Through empirical validation and case studies, the effectiveness and utility of the proposed tool in enhancing the reliability and interoperability of IoT ecosystems are demonstrated.

BLOCKCHAIN-POWERED VOTING: ENHANCING SECURITY, TRANSPARENCY AND ACCESSIBILITY IN DIGITAL DEMOCRACY

ABSTRACT

The use of technology has become important at this point in helping to meet human needs. Due to the increasing use of technology, new challenges are brought in the process of democracy as most people today don't trust their governments, making elections is very important in modern democracy. Elections have a great importance in determining who will rule a nation or an organization or it can be said as it is an event that decides the fate of any nation. Building a secure electronic voting system that offers the fairness and privacy of current voting schemes, while providing the transparency and flexibility offered by electronic systems has been a challenge for a long time. In this work-in-progress paper, we evaluate an application of blockchain as a service to implement distributed electronic voting systems.

The paper proposes a novel electronic voting system based on blockchain that addresses some of the limitations in existing systems and evaluates some of the popular blockchain frameworks for the purpose of constructing a blockchain-based e-voting system. In particular, The blockchain is said as emerging, decentralized, and distributed technology that promises to enhance different aspects of many industries. Expanding e-voting into blockchain technology could be the solution to eliminate the present concerns in e-voting system the process of an election, and the implementation of a blockchain-based application, which improves the security and decreases the cost of hosting a nationwide election.

ABSTRACT

Over the past decade, cyber attacks have increased in frequency, impact and sophistication, largely due to the integration of artificial intelligence (AI). This technology, while providing organizations with the ability to strengthen their cyber defenses, also presents a dual challenge in cyber security. On the one hand, AI empowers organizations to strengthen their security measures, yet on the other hand, it provides cybercriminals with the means to plan highly targeted and rapidly scalable attacks that can evade traditional detection methods. This growing prevalence of AI-driven cyberthreats underscores the paradoxical nature of AI as a tool to both enhance and mitigate cybersecurity. As cyber threats continue to evolve, there is a great need for advanced technology to effectively detect and respond to attacks. In this context, AI has emerged as an indispensable tool, enabling comprehensive threat detection and automated response mechanisms to protect digital assets and networks.

INTRODUCTION

In the ever-evolving landscape of cybersecurity, the integration of artificial intelligence (AI) has emerged as a pivotal factor shaping the dynamics of digital defense and offense. Over the past decade, the frequency, impact, and sophistication of cyberattacks have surged, propelled by the capabilities afforded by AI technology. While AI offers promising avenues for organizations to bolster their cyber defenses, it also presents a dual-edged sword, confronting cybersecurity professionals with formidable challenges. On one front, AI empowers organizations to enhance their

security measures, leveraging advanced algorithms and automation to fortify digital perimeters. However, on the other front, AI equips cybercriminals with potent tools to orchestrate targeted and scalable attacks, capable of evading traditional detection mechanisms. This juxtaposition of AI as both a solution and a threat underscores the paradoxical nature of its role in cybersecurity.

As the cyber threat landscape continues to evolve at an unprecedented pace, the imperative for advanced technologies to detect and respond to these threats becomes increasingly urgent. In this context, AI has emerged as an indispensable ally, offering the promise of comprehensive threat detection and automated response mechanisms to safeguard vital digital assets and networks against the relentless onslaught of cyber adversaries. This paper delves into the intricate interplay between AI and cybersecurity.

EVOLUTION OF AI-DRIVEN IN CYBERSECURITY:

The evolution of cybersecurity over the past several decades has been marked by significant advancements in technology and methodologies aimed at combating increasingly sophisticated threats. It all began with the early adoption of statistical methods and expert systems in the field, which laid the foundation for rules-based detection systems. These early systems were instrumental in identifying and mitigating known threats, but they were limited in their ability to adapt to new and evolving attack vectors[1]. Moreover, there has been a significant shift from reactive, signature-based tools to proactive cybersecurity measures augmented by artificial intelligence (AI) [2]. By leveraging AI-driven analytics and automation, security operations teams can detect and respond to threats in real-time, minimizing the

impact of cyber attacks and reducing the likelihood of future breaches. This proactive approach to cybersecurity is essential in an increasingly interconnected and digitized world, where the potential consequences of a successful cyber attack can be devastating

AI BASED THREAT DETECTION:

AI possesses a unique capability to analyse vast amounts of data at an unprecedented speed, far surpassing the capabilities of human analysts [3]. This proficiency is rooted in the advanced algorithms and computational power that underpin AI systems, enabling them to sift through massive datasets comprising diverse sources of security telemetry with remarkable efficiency.

Here's a brief explanation of how AI can analyse data to identify anomalies and potential threats faster than humans:

Advanced Algorithms: AI systems leverage sophisticated algorithms, including but not limited to ML and DL, to process and analyse large volumes of data. These algorithms are designed to learn from data patterns, adapt to new information, and make predictions or decisions based on the insights derived from the data [4].

Parallel Processing: AI systems are capable of parallel processing, allowing them to analyse multiple data streams simultaneously. Unlike human analysts who are limited by cognitive capacity and attention span, AI can handle massive datasets in parallel, significantly reducing the time required for analysis [5].

Real-time Analysis: AI systems can perform real-time analysis of streaming data, such as network traffic logs and system event logs, as it is generated [6]. This enables organizations to detect and respond to security threats in real-time, minimizing the impact of potential cyber-attacks.

Pattern Recognition: AI excels in identifying patterns, anomalies, and deviations within data. By analysing historical data and learning from past incidents, AI can recognize abnormal behaviours or activities that may indicate a potential security

threat [7]. This pattern recognition capability enables AI to flag suspicious events quickly and accurately.

Automation: AI-driven automation streamlines the data analysis process, eliminating the need for manual intervention at every step. Once trained, AI systems can autonomously analyse data, identify anomalies, and trigger alerts or responses based on predefined criteria [8]. This automation significantly accelerates the pace of threat detection and response, enabling organizations to react swiftly to emerging cyber threats.

Scalability: AI systems are highly scalable and capable of handling increasingly large and complex datasets without sacrificing performance [9]. AI can scale horizontally as data volumes grow by distributing computation across multiple processors or nodes, ensuring consistent and efficient analysis even as the data load increases.

AI BASED VULNERABILITY SCANNING:

AI can revolutionize vulnerability scanning and prioritize critical vulnerabilities by applying machine learning algorithms to analyse extensive datasets. AI-powered vulnerability scanners automate the process of identifying potential security weaknesses across software code, system configurations, and network assets. These scanners utilize sophisticated algorithms to detect patterns, anomalies, and historical attack data, enabling them to uncover vulnerabilities that may have previously gone unnoticed.

The automation of vulnerability scanning using AI has several significant impacts:

Efficiency: By automating vulnerability scanning, AI-driven systems significantly reduce the time and effort required to identify and remediate security weaknesses. This efficiency allows organizations to conduct more frequent scans and assessments, ensuring continuous security posture monitoring [10], [11].

Prioritization: AI-powered vulnerability scanners can prioritize vulnerabilities based on their severity, exploitability, and potential impact on the organization's

security posture. By assigning risk scores or ratings to vulnerabilities, these systems enable security teams to focus their remediation efforts on addressing the most critical threats first, thereby maximizing the effectiveness of their security measures [12].

Resource Allocation: By prioritizing critical vulnerabilities, AI-driven systems help organizations allocate their resources more effectively [13]. Security teams can direct their attention and resources towards addressing high-risk vulnerabilities that pose the greatest threat to the organization's assets and data, thereby reducing the overall risk of a successful cyber-attack.

Accuracy: AI algorithms excel at identifying subtle patterns and anomalies within complex datasets, enabling them to accurately identify vulnerabilities that may be overlooked by traditional methods [13], [14]. This enhanced accuracy reduces the likelihood of false positives and false negatives, ensuring that security teams can trust the results generated by AI-driven vulnerability scanners [14].

Adaptability: AI-powered vulnerability scanners can continuously learn and adapt to new threats and attack techniques, ensuring that organizations remain protected against evolving cyber threats [11], [12]. By analyzing historical attack data and security trends, these systems can update their models and algorithms to detect previously unseen vulnerabilities and attack vectors, thereby enhancing the organization's resilience to emerging security risks [14].

AI DRIVEN CYBER ATTACKS:

AI-driven cyberattacks are emerging as a major threat, as they are becoming more sophisticated and diverse [15]. It is not yet clear how this will affect the future of cyber crime and warfare. However, the potential for AI-driven cyberattacks has become a serious concern . AI can provide a powerful toolkit for cyber adversaries [16], to enhance all types of conventional cyberattacks, including phishing, malware, password attacks, and even manipulation of AI models themselves .

To combat AI-driven cyberattacks effectively, it is essential to understand the attack vectors, vulnerabilities, and motivations of the attackers. Various researchers have investigated this topic , revealing several common motivations that security professionals and organisations should be aware of. However, these motivations can vary depending on the threat actor and attack type [17]. For example, attackers may be motivated by financial gain, political or strategic goals, or the desire to cause harm . Understanding attacker motivations can also help incident response teams prioritise strategies, adapt response tactics, anticipate attack techniques, improve detection capabilities, and develop security countermeasures. This empowers response teams and professionals to mitigate the immediate impact of an attack and minimise future incidents [18]. This growing complexity and diversification of AI-driven cyberattacks necessitate a thorough exploration to inform our understanding and response strategies.

Types of AI driven cyber attacks:

The offensive AI (deploys AI techniques to attack computer systems and networks)

Adversarial AI (maliciously exploits and/or attacks AI/ML systems and data)

Offensive AI-driven :

An offensive AI-driven cyber attack involves the use of artificial intelligence technology to carry out malicious activities. This could include automating phishing campaigns, crafting sophisticated malware that adapts to defensive measures, or exploiting vulnerabilities in systems at scale. Offensive AI attacks leverage machine learning algorithms to optimize their strategies, evade detection, and inflict maximum damage on targeted systems or networks, posing significant threats to cybersecurity.

ADVERSARIAL AI-DRIVEN :

An adversarial AI-driven cyber attack involves manipulating AI systems by injecting malicious input data, exploiting vulnerabilities to deceive or compromise

the system's functionality. These attacks often aim to bypass security measures, manipulate decision-making processes, or cause AI models to make incorrect predictions, ultimately leading to disruptions, data breaches, or unauthorized access to sensitive information. Countermeasures involve robust model training, input validation, and continuous monitoring to detect and mitigate adversarial manipulation.

AI BASED INCIDENT RESPONSE:

AI offers significant potential in automating repetitive tasks during incident response, thereby expediting remediation efforts and enhancing the overall efficiency of security operations. AI-powered incident response platforms leverage advanced algorithms, including machine learning and natural language processing, to analyse security alerts, prioritize incidents, and execute predefined response actions autonomously. These platforms are capable of handling large volumes of security alerts in real-time and can make data-driven decisions to address security incidents swiftly and effectively.

The integration of AI-driven automation into incident response processes yields several notable impacts [19]–[21]:

Acceleration of Incident Response Times: By automating repetitive tasks such as triaging security alerts, categorizing incidents, and initiating predefined response actions, AI significantly reduces the time required to detect and respond to security incidents. This swift response helps minimize the window of opportunity for attackers, mitigating the potential impact of security breaches on the organization.

Reduction of Human Error: AI-driven automation minimizes the risk of human error inherent in manual incident response processes. By consistently applying predefined response actions based on predefined rules and algorithms, AI ensures a consistent and reliable approach to incident handling, reducing the likelihood of oversight or misinterpretation of security data.

Enhancement of Overall Security Posture: By freeing up security personnel from mundane and repetitive tasks, AI enables them to focus on more strategic and high-value activities, such as threat hunting, analysis, and proactive security measures. This shift towards proactive security measures strengthens the organization's overall security posture, making it more resilient against evolving cyber threats.

Scalability and Flexibility: AI-powered incident response platforms are highly scalable and adaptable to changing threat landscapes and organizational requirements. These platforms can handle large volumes of security alerts and incidents without sacrificing performance, ensuring that organizations can effectively respond to varying complexity and scale security incidents.

Continuous Learning and Improvement: AI algorithms can learn from historical incident data and feedback from security analysts, continuously improving their performance and accuracy over time. By leveraging machine learning techniques, AI-driven incident response platforms can adapt to new threats, trends, and attack techniques, enhancing their effectiveness in detecting and mitigating security incidents.

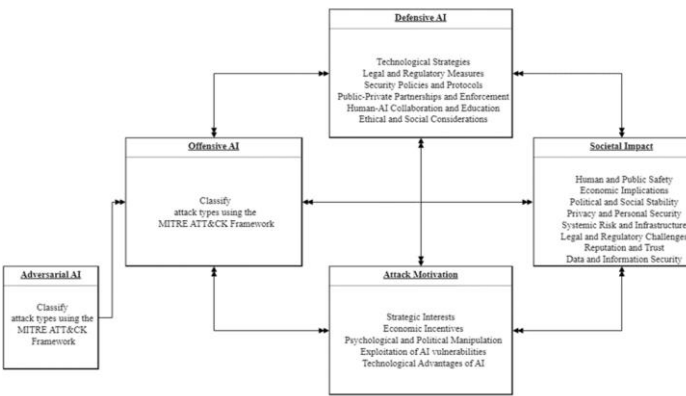

MITIGATION OF AI-DRIVEN CYBER ATTACKS:

The strategies and techniques that can be utilised to mitigate AI-driven cyberattacks. The SLR(Security Lifecycle Review) revealed a growing body of research on defensive AI against AI-driven cyberattacks. In this section, we synthesised these findings, providing a comprehensive overview of the state-of-the-art approaches to safeguarding against the vulnerabilities introduced by offensive and adversarial AI.

The various defensive AI strategies and techniques are to mitigate the risks of AI-driven cyberattacks, it is equally important to explore the motivations behind these sophisticated attacks. Understanding the underlying motivations not only enhances our understanding of the threat landscape but also equips us to proactively address vulnerabilities before they can be exploited.

AI CYBERSECURITY DIMENSIONS (AICD) FRAMEWORK

As the main contribution of the study, the AICD Framework is a comprehensive, multidimensional conceptual model that encapsulates the diverse dimensions of AI-driven cyberattacks. It draws insights from four primary research objectives: attack types, mitigation strategies, underlying motivations, and societal impact. The framework provides an integrated perspective for academics, policymakers, industry professionals, and cybersecurity experts, facilitating a holistic understanding of the dynamics and implications of AI-driven cyber threats. The AICD Framework underscores the importance of a multidimensional approach to addressing the intricate challenges arising from the synergy of AI techniques and cyberattacks. It highlights the necessity for proactive interdisciplinary collaboration in both research and practical applications

AICD Framework:

Overall, the AI Cybersecurity Dimensions Framework serves as a valuable tool for organizations to navigate the complexities of AI-driven cybersecurity and develop holistic approaches to protect against evolving threats in the digital landscape.

ETHICAL AND PRIVACY CONSIDERATION :

Potential Ethical Implications of AI in Cybersecurity : The potential ethical implications of AI in cybersecurity are described below [22], [23]:

Automated Decision-Making: The use of AI in cybersecurity raises concerns about automated decision-making, where AI algorithms autonomously detect and respond to security threats. Ethical considerations arise regarding the accountability and transparency of these decisions, especially when they impact individuals' rights and freedoms.

Weaponization of AI: There are ethical concerns surrounding the potential weaponization of AI in cyber warfare and offensive cyber operations. The development and deployment of AI-powered cyber weapons raise questions about the morality of using AI to conduct attacks and the potential for unintended consequences or collateral damage.

Surveillance and Privacy: AI-driven cybersecurity measures, such as intrusion detection systems and network monitoring tools, may inadvertently infringe on individuals' privacy rights by capturing and analysing their digital activities without their consent. The ethical implications of mass surveillance and data collection must be carefully considered to balance security needs with individual privacy rights.

Privacy Concerns Associated with AI-Driven Security Measures: The privacy concerns associated with AI-Driven Security measures include [24], [25]:

Data Collection and Usage: AI-powered security measures rely on extensive data collection and analysis, raising concerns about individuals' personal information privacy. Unauthorized access to sensitive data or misuse of personal information by AI algorithms could lead to privacy violations and breaches of confidentiality.

Algorithmic Bias: AI algorithms used in cybersecurity may exhibit biases that disproportionately impact certain individuals or groups. Biased algorithms could result in discriminatory outcomes, such as false positives or unfair targeting, leading to privacy concerns and potential harm to affected individuals.

Third-Party Risks: Outsourcing AI-driven security measures to third-party vendors or service providers introduces privacy risks, as organizations may have limited control over how their data is collected, processed, and protected. Ensuring

the privacy and security of data shared with third parties is essential to mitigate the risk of data breaches or unauthorized access.

BENEFITS AND ADVANTAGES OF AI IN CYBERSECURITY:

Speed and Efficiency :AI-powered systems can analyse vast amounts of data in real-time, enabling rapid threat detection and response. This speed is critical in mitigating the damage caused by cyberattacks.

Adaptability: AI models continuously learn and adapt to new threats, making them highly effective in countering evolving attack techniques. This adaptability reduces the reliance on static rule-based systems that quickly become outdated.

Scalability: AI-driven solutions are scalable, making them suitable for organizations of all sizes. They can handle the increasing volume of data generated in today's digital landscape without a proportional increase in human resources.

FUTURE DIRECTION IN AI AND CYBERSECURITY :

Explainable AI (XAI) :

The development of Explainable AI is crucial for transparency and trust in AI-powered security systems. XAI aims to make AI decisions more understandable and interpretable, helping security analysts and auditors to comprehend the rationale behind AI-driven decisions.

Quantum Computing Threats and Defenses :

As quantum computing matures, it poses both threats and opportunities in cybersecurity. AI will play a vital role in developing quantum-resistant encryption and security algorithms.

Collaboration with Human Analysts :

The future of AI in cybersecurity lies in close collaboration between AI systems and human analysts. While AI can automate many tasks, human expertise remains essential for complex decision-making and understanding the broader context of threats.

CONCLUSION

The integration of artificial intelligence (AI) into cybersecurity has ushered in a new era of both promise and peril. While AI offers unparalleled capabilities to fortify digital defenses and mitigate cyber threats, its adoption also exposes organizations to sophisticated and rapidly evolving attack vectors orchestrated by cybercriminals leveraging AI-driven techniques. This paradoxical nature of AI underscores the need for a multifaceted approach to cybersecurity that embraces AI as a powerful ally while also acknowledging and addressing the inherent risks it introduces. The evolving landscape of cyber threats necessitates proactive measures and continuous innovation to stay ahead of adversaries, with AI serving as a cornerstone in the arsenal of cybersecurity tools. By leveraging AI for threat detection, vulnerability scanning, incident response, and beyond, organizations can bolster their resilience against the relentless onslaught of cyber adversaries in an increasingly digitized world.

Looking ahead, the future of AI in cybersecurity holds immense promise, but also requires careful consideration of ethical, privacy, and societal implications. As AI continues to evolve, efforts to enhance transparency, accountability, and fairness in AI-powered security systems will be paramount. Collaborative initiatives between AI systems and human analysts, coupled with advancements in Explainable AI (XAI) and quantum-resistant encryption, will shape the next frontier of cybersecurity. By fostering interdisciplinary collaboration and adopting a holistic approach that balances innovation with ethical considerations, organizations can navigate the complexities of AI-driven cybersecurity and forge a path towards a more secure and resilient digital future.

ABSTRACT

Brain stroke, a critical medical condition, requires prompt diagnosis and treatment to minimize its adverse effects. Machine learning techniques have shown promise in aiding the early detection of brain stroke through medical imaging analysis. This study proposes the utilization of two advanced deep learning architectures, namely ResNet and U-Net, for the automated detection and segmentation of brain stroke. ResU-Net, an enhanced version of U-Net used incorporates residual connections to improve information flow and model performance. Leveraging a dataset comprising medical images of stroke-afflicted brains, the proposed models are trained to accurately segment and classify regions indicative of stroke presence. Metrics including accuracy, sensitivity, specificity, and Dice coefficient are used to evaluate the models ability to detect the brain damage. The ability of all three layouts in precisely identifying brain stroke locations is demonstrated by experimental data. The U-Net exhibits slightly superior performance over ResNet. Performance of ResU-Net in the proposed approach holds promise for assisting healthcare professionals in early diagnosis and further refinement and validation of these models on larger and diverse datasets enhance their generalizability and clinical utility in real-world settings. Real-time image capture and classification, along with immediate feedback, contribute to its mission of advancing stroke diagnosis and potentially saving lives through AI-driven healthcare improvement.

INTRODUCTION

A stroke can happen due to the disruption of blood flow to the brain, potentially harming or even killing brain cells. Recent research in brain stroke detection focuses on leveraging advanced medical imaging techniques such as CT and MRI, coupled with artificial intelligence (AI) algorithms, for early and accurate diagnosis [2]. Deep learning models, trained on large datasets of medical images, demonstrate promising results in automatically detecting stroke symptoms and determining stroke type and severity[2],[23]. There are other algorithms available for diagnosing brain strokes, the reason we choose the ResU-Net method is because it performs better than the others. It combines two different models and segmented the brain stroke more preciously than other architecture already proposed. Thus, it has a high degree of accuracy.

The AI architecture combining residual learning and U-Net structures, forms a robust framework capable of handling intricate features within CT scans. Its design prioritizes high-resolution imaging, enabling the capture of minute details within brain scans [1]. This intricate level of detail retrieval is pivotal in identifying subtle abnormalities associated with strokes that might be imperceptible to the human eye or conventional imaging software. In the realm of healthcare, the quest for swift and precise diagnosis is paramount, particularly in critical conditions such as strokes. The project stands as a pioneering venture, harnessing the ability of AI architecture, ResU-Net to revolutionize the detection and classification of brain strokes.

This groundbreaking initiative embarks on a mission to amalgamate cutting-edge technology and medical diagnostics, facilitating healthcare professionals in promptly and accurately identifying strokes in CT scans [6],[17]. Through the utilization of ResU-Net's advanced AI architecture, renowned for its robustness and

fine-grained image analysis capabilities, the project aims to augment the efficiency of stroke diagnosis, potentially saving invaluable time in crucial interventions and ultimately, lives. It exemplifies a convergence of innovation and ethical responsibility. The system offers a rapid and intuitive means for healthcare practitioners to analyse brain scan images, providing swift assessments without compromising on ethical considerations or data privacy.

The objective of this project is tri-fold in its ambition. Firstly, it endeavours to develop a user-friendly component employing the ResU-Net architecture offering real-time results for stroke detection and classification. Secondly, it aspires to empower healthcare professionals by furnishing them with a tool that facilitates swift identification and categorization of strokes in CT scans, ensuring data privacy and upholding ethical standards. Finally, continuous refinement and user education remain pivotal in the project's evolution, aimed at advancing stroke diagnosis methodologies, thereby enhancing patient care and outcomes.

The methodology employed in this visionary endeavour is comprehensive and meticulously structured. It encompasses data collection and preprocessing, model development, classification, display of immediate feedback, and rigorous testing and validation. It is an innovative project poised to usher in a new era in healthcare technology. As it navigates the frontier of AI-driven healthcare improvement, this initiative holds the promise of not only transforming stroke diagnosis but also setting a precedent for ethical AI integration in critical medical domains.

PROPOSED METHODOLOGY

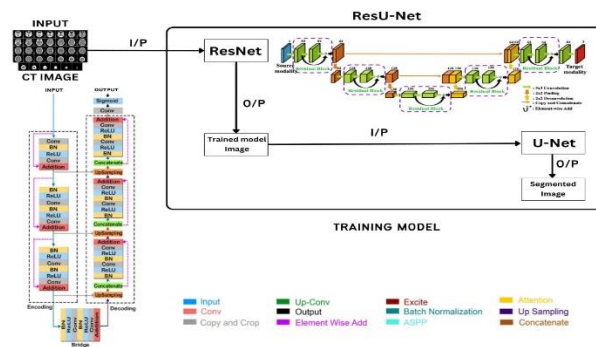

Fig 1: Block diagram of brain stroke detection

The block diagram of proposed work of brain stroke detection is shown in fig 1. The process includes the following sequence of steps.

Data Gathering and Preprocessing:

Data Gathering: Obtained brain scan images from open sources like Kaggle and ensuring the dataset includes a sufficient number of stroke and non-stroke cases.

Preprocessing: It includes cleaning the data by standardizing the images, resizing them to a uniform size, and potentially applying filters or normalization techniques to enhance their quality. Additionally, label the images accurately to denote stroke and non-stroke cases.

ResNet Model:

Implemented a Residual Network (ResNet) architecture, from scratch and configured the ResNet model to take CT images as input. Train the ResNet model using a suitable loss function and optimizer to learn features from the CT images.

U-Net Model:

Implemented a UNet architecture, which is commonly used for biomedical image segmentation tasks. Configure the UNet model to take the feature maps generated by the ResNet as input. Train the UNet model to perform segmentation on the feature maps, predicting stroke segmentation masks.

Model Training:

The proposed models are trained using the pre-processed dataset, with appropriate hyperparameters selected through cross-validation or grid search. The training process involves iterative optimization of the model weights using optimization algorithms like stochastic gradient descent (SGD) or Adam. The model's performance is monitored using validation metrics such as Dice coefficient ensure the convergence towards an optimal solution.

ResU-Net:

The ResU-Net is the combined architecture of ResNet and U-Net. The ResNet serves as the encoder part, extracting features from the input CT images. The UNet acts as the decoder part, generating high-resolution segmentation masks. Initialize the ResU-Net model with weights from the pre-trained U-Net models. This gives the high precision output when compared to U-Net.

Segmented Image Generation:

The final output of the ResU-Net model represents the segmented image, wherein the stroke-affected regions are accurately delineated from the surrounding brain tissue. This segmented image provides valuable insights to healthcare professionals for diagnosing and assessing the extent of brain stroke, enabling timely intervention and treatment planning.

Testing:

The trained model is tested for a sample input image. Which the model does not seen earlier and The model's performance is assessed both for U-Net and ResU-Net.

CONFUSION MATRIX FOR U-NET

The fig 2, shown below describes the confusion matrix of U-Net architecture

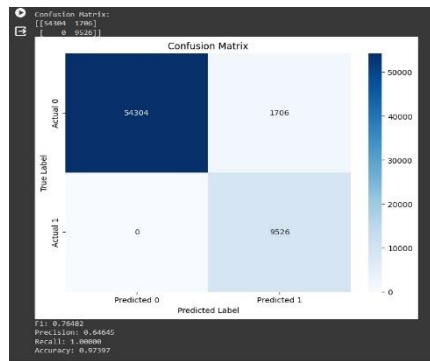

Fig 2: Confusion matrix for U-Net

The evaluation metrics play important roles in determining how successful a machine learning model is developed for brain stroke detection. The U-Net architecture does the stroke diagnosis with an accuracy of 0.97397 and precision 0.64645.

CONFUSION MATRIX FOR RESNET

The fig 3 shown below describes the confusion matrix of ResNet architecture

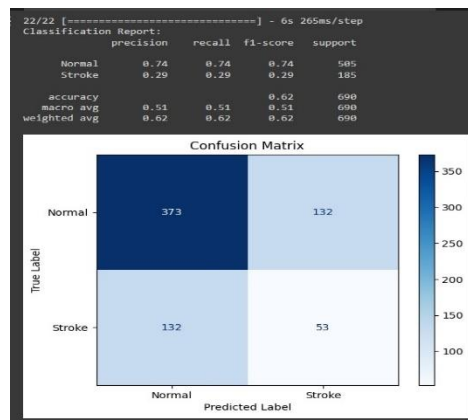

Fig 3: Confusion matrix for ResNet

The confusion matrix for a ResNet algorithm have a significant impact on a machine learning model's effectiveness. This breakdown allows for quantitative evaluation metrics identifying misclassifications and informing decision-making for model refinement and improvement. The above fig 3, shows the accuracy of the ResNet model is 0.62.

CONFUSION MATRIX FOR RESU-NET

The fig 4 shown below describes the confusion matrix of ResU-Net architecture

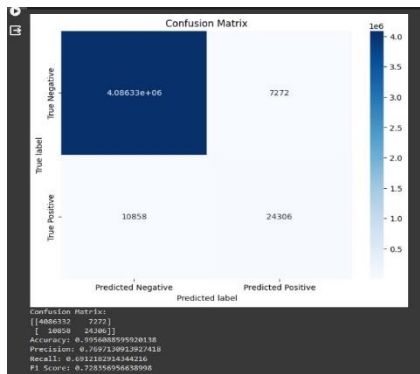

Fig 4: Confusion matrix for ResU-Net

Among the total instances, the model correctly identifies brain strokes of approximately 99.56% of cases with a Precision of (0.7697) approximately.

The model's recall (0.6912) indicates its accuracy in identifying every positive case. A perfect recall score (0.6) implies that the model captures all instances of brain strokes in the dataset without any FN.

The precision and recall harmonic mean is represented by the F1 Score (0.7283). It provides an accurate assessment of a model's balance, taking into account both FP and FN. The low F1 score here suggests the measures of the proposed work, indicating that the model might struggle with correctly identifying both positive and negative cases of brain strokes simultaneously.

ACCURACY AND LOSS

The results obtained by training the ResNet architecture are shown in fig 5 & 6 respectively. This figures presumably contains a graphs of the outcomes of the model. Given that accuracy is the ratio of a model's correct predictions to its total number of predictions, it is an essential parameter in machine learning and deep learning applications. It offers a straightforward and natural comprehension of the model's functionality. By calculating the discrepancy between the target output and the projected output, the loss measures the model's performance. Plotting accuracy

and loss versus The number of epochs, or training iterations, allows one to gain insight into how well the machine learning algorithm learns from the input.. Accuracy tends to increase, while loss decreases during training epochs. Metrics used for validation show how effectively the model applies to new data.

Fig 6: ResNet model validation and training Loss

The fig 7, fig 8 and fig 9 shown below describes the Dice and validation dice coefficient, Accuracy and loss of U-Net architecture.

Fig 7: U-Net model validation and dice coefficient

The Dice coefficient provides a quantitative measure of segmentation performance, guiding model selection and fine-tuning.

Fig 8: Accuracy and validation accuracy of U-Net

The U-Net model has an accuracy of 0.97. which is greater than the already existing work. This increase in accuracy is due to the increase in the number of training epochs and dataset size.

Fig 9: Loss and validation loss of U-Net

The fig10, fig11 and fig12 describes the Model accuracy, Model loss and Dice coefficient of ResU-Net architecture.

Fig 10: Model accuracy of ResU-Net

Model accuracy serves as a primary metric for evaluating and comparing the effectiveness of models for machine learning. It helps in selecting the most effective algorithm for a given task and monitoring improvements over time. The accuracy of ResU-Net model is found to be high compared to the two base DNN models ResNet and U-Net.

Fig 11: Model loss of ResU-Net

Model loss, typically calculated during the training phase, determines how much the variation between the actual and anticipated values. It serves as a guiding metric for optimizing model parameters to minimize error, facilitating better convergence towards accurate predictions.

Fig 12: Dice coefficient of ResU-Net

By optimizing the network to maximize the Dice coefficient, ResU-Net improves the accuracy of segmenting objects in images. This metric helps in training the model

to capture limits and subtle details of segmented regions, accurately leading to more precise segmentation results.

RESULT AND OUTPUT

The sample input image shown in fig 13a and grounded mask image shown in fig 13b are applied as input for the models U-Net and ResU-Net. Fig 13c and fig 13d represents the predicted output obtained from the trained models.

Fig 13a: Input image

Fig 13b: Grounded mask

Fig 13c: Predicted U-Net Output

Fig 13d: Predicted ResU-Net Output

The U-Net predicted output provides a segmented image with enhanced delineation of structures with the accuracy of 0.97. Whereas, the ResU-Net predicts the stroke portion with an accuracy of 0.9956, as shown in Fig. 13d above. When considering the performances of U-Net, ResU-Net provides greatest accuracy for the same input image and thus helps to diagnose stroke effectively and efficiently.

The comparison of the proposed work with other existing models output reveals that the accuracy of stroke segmentation is highest in the proposed combined DNN architecture, ResU-Net.

CONCLUSION

The proposed method offers real-time stroke detection and classification. Powered by U-Net, ResU-Net enhances healthcare by enabling rapid and accurate diagnoses. With its portability and affordability, it addresses critical medical needs, paving the way for improved stroke care worldwide. The commitment to ongoing refinement ensures its continued impact in healthcare technology. The proposed AI model stands as a beacon of progress, promising better outcomes for stroke affected patients and offers the best solution for healthcare. The ResU-Net combines the strengths of both ResNet and U-Net architectures for deep feature extraction and precise localization, resulting in improved segmentation performance with effective utilization of both local and global context information. As a result, the proposed ResU-Net model for stroke detection provides efficient health care solution and saves human life. Further, the developed model can be incorporated in a hardware, so that it is portable and the people can quickly diagnose themselves early and could save their life.

ABSTRACT

This project Aims to enhance passenger Safety and comfort In automated metro train system through the integration of advanced technologies. Building upon existing driverless metro train system, our focus is on implementing additional features such as real time passenger monitoring, emergency response system and improved interior design system for enhanced comfort. This project utilizes a combination of sensors, communication technologies and ergonomic design principles to ensure a seamless and secure travel experience for passengers. Through this enhancement, we aim to address potential safety concerns and elevate the overall passenger experience in automated metro trains systems

INTRODUCTION

This project is designed so that students can understand the technology used in now-a day's driverless metro trains which are utilized as a part of the greater part of the created nations like Germany, France, and Japan. At whatever point the prepare touches base at the station its tops naturally, as detected by an IRsensor. At that point the entry way is opens consequently so that the travelers can go inside the prepare. The entry way then closes after an end or set time set in the controller by the program. This implanted application mainly focuses on overcoming escape clauses in the current framework. It is advanced to meet the cost and power utilization necessities.

LITERATURE REVIEW

If a train is operated in a circular or straight path, it does not require a pilot. In order to provide this facility in Metrorail system, we are using Programmable Logic Controllers for automatic operation of Metrorail and it is monitored by using SCADA to track the location of the train. When a train meets an obstacle, the sensor installed in the Metrorail system will sense the object and reduces its speed and hence the accidents are avoided.

Train using voice IC and the radio frequency wireless card for tracking the station data. The paper consists of microcontroller with the RF receiver and the voice recorder chip with speaker. The whole system is attached to the vehicle (BUS or Train). The encoded RFID tags are placed in the BUS stops or the railway stations. The microcontroller in the TRAIN is programmed in such a way that every station name saved in the voice chip which is having a unique code.

This paper presents possible enhancements of the PHY layer of these systems based on MIMO techniques with and without channel state information at transmitter in order to increase system performance without increasing the number of deployed access points and the transmitted power. The tunnel scenario with a masking train in the case of low and high spatial correlation is modeled thanks to the Kroenke model obtained with a 3D ray tracing tool.

This proposed system is a driverless metro train and which eliminates the need onboard staff and makes the complete autonomous train. Thus, any human error is removed from the system. In this project ARM 7 has been used as CPU. When the train reaches the source or the destination station the train stops and start automatically as sensed by an IR sensor. Then the door of the train opens automatically and the passenger can enter into the train and leave from the train and after the prescribed time which set in the microcontroller program the door of the train closes automatically.

This train is equipped with a controller that enables the automatic stopping of the train from station to station. This paper presents the development process of a prototype for a driverless train implemented using a PIC microcontroller. Simulation for the system's circuits is done with the aid of Proteus software. The hardware circuits, which are built on printed circuit boards (PCB), are interfaced with actuators and sensors for automation purposes. The hardware is assembled in a toy-like prototype train. The C programming language is used for programming the microcontroller.

This paper presents a metro traffic model which accounts for energy consumption. Thereby, Dual Heuristic Dynamic Programming (DHP) technique is employed to find an optimal ATR design with energy saving. Simulation tests of the ATR design are conducted with field data. Results show that designing the ATR with energy saving by using DHP method would be feasible and tractable. In addition, traffic regulation with better energy efficiency is attainable with the ATR design through coasting and dwell time control.

Automatic train regulation (ATR) dominates the service quality, transport capacity, and energy usage of a metro-line operation. The train regulator aims to maximize the schedule/headway adherence while minimizing the energy consumption. This paper presents a traffic-energy model to characterize the complicated dynamics with regard to the traffic and the energy consumption of a metro line, and devises an adaptive-optimal-control (AOC) algorithm to optimize the train regulator through reinforcement learning. The updating rules for reinforcement learning are deduced from the discrete minimum principle. Testing with field traffic data, the AOC algorithm succeeds in the optimization of the train regulator; no matter the system is disturbed by passenger-flow fluctuations or by frequently minor delays.

This paper shows the form of the optimal solution and how to minimize energy of the train driving control that can be included into Automatic Train Operation (ATO)

systems. We consider the case where a train is to be driven by automatic operation mode along a non-constant gradient, curve and with speed limits. Using the genetic algorithms (GA), we constructed optimal train driving strategy. The results are compared with P. Howett's the optimization method using the constrained optimal technique (Lagrange Function & Kuhn-Tucker equations) in view of energy cost benefit.

PROPOSED SYSTEM

For the existing system not accuracy to automatic train moving so go for our proposed system of "IR BASED ON SMART METRO TRAIN SYSTEM" so added the new technique

In our project we employed a new technique for plc microcontroller are used our system because pic microcontroller are accuracy and low cost can easily have implemented and easily used.

Advantages of proposed system

- Easy way of transport from and to remote area.
- Fully air conditioning trains.
- By using the automatic train systems, we can travel a safe journey.
- High speed technology
- Modernity
- accessibility

Selecting a Template (Heading 2)

First, confirm that you have the correct template for your paper size. This template has been tailored for output on the A4 paper size. If you are using US letter-sized paper, please close this file and download the file “MSW_USltr_format”.

Maintaining the Integrity of the Specifications

The template is used to format your paper and style the text. All margins, column widths, line spaces, and text fonts are prescribed; please do not alter them. You may note peculiarities. For example, the head margin in this template measures proportionately more than is customary. This measurement and others are deliberate, using specifications that anticipate your paper as one part of the entire proceedings, and not as an independent

The IR LED-photodiode arrangement is placed such that both are placed parallel to each other. The photodiode doesn't get the light pulses; result the microcontroller will get a high signal. The IR LED gets reflected by any object (suppose the station signal), Result the microcontroller will get a low signal.

The microcontroller also sends a high signal to the door motor driver such that it drives the motor to open the door. The time end the microcontroller sends a low signal to the door motor driver such that it drives the motor to close the door.

The IR LED-photodiode arrangement, when a person entre the door, there is interrupt between the IR LED and the photodiode send a logic high signal to microcontroller. When the person leaves the door, there is interrupt between the IR LED and the photodiode send a logic low signal to microcontroller.

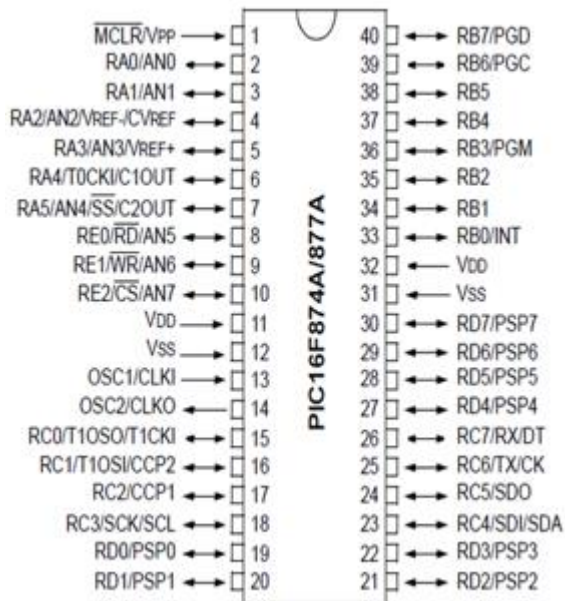

HARDWARE DESCRIPTION

General Requirement

The requirement for the project automatic moving train with help of IR sensor and passenger counting systems also. The specification of each and every requirement is mentioned below.

pic microcontroller

Here we used PIC16fxx40 pin for performing multi functions within same pin. The microcontroller sends the data to PC through MAX232. The data is sent to PC for a specified time interval. The PC thus sends the information to the GSM using MAX232 further it is sent to mobile through message. The PIC microcontroller is popular among industries and other purposes because of the availability of microcontrollers at low cost and small circuits.

DISTANCE MEASURING FOR IR

This circuit is consisting of the two IR sensor one for front side and another one for back side of the train. for forward and reverse in same signal direction. And IR sensor using the passenger counting systems interrupt between the entry and leaving.

Software Description

For IR based metro train, we had developed the program using MICROSOFT C and used dot net and visual studio for displaying the control parameters. the simulation of our project was done with the help of PROTIUS software.

CONCLUSION

Nowadays the accidents of trains are increasing day by day. Of these major accidents are occurring due to human faults. A man can do a mistake but a programmed processor doesn't have a chance of doing error. This is the main reason behind this project. This is a highly advanced technology which is currently used in developed nations such as Japan, Germany, France etc. By using this auto metro train, the timings of the train will be exact and it avoids a lot of inconvenience to the passengers. This project will greatly reduce the human intervention in the control of trains and hence saves a lot of time and money. Thus the project "IR BASED ON SMART METRO TRAIN FOR CROWD MANAGEMENT" is greatly useful in all aspects.

ABSTRACT

Agriculture is a critical sector for sustaining human life, and the demand for increased crop yield, quality, and resource efficiency has never been higher. To address these challenges, this research presents a novel approach to crop growth monitoring through the integration of system adaptivity and edge Artificial Intelligence (AI) technologies. The proposed system leverages a combination of advanced sensors, edge computing, and AI algorithms to provide real-time monitoring and analysis of crop growth. Traditional approaches to crop monitoring rely heavily on centralized data processing, which can lead to latency issues, data security concerns, and increased operational costs. In contrast, our approach utilizes edge AI to process data directly at the source, reducing latency and ensuring data privacy. The system's adaptability is achieved through a smart system management mechanism that dynamically adjusts cryptographic functions based on security needs and resource constraints. This approach ensures that the system can safeguard sensitive sensor data without compromising performance or energy efficiency.

INTRODUCTION

Lately, the abnormal climate leads to the extreme rainfall, while the circumstance of natural disasters similar as typhoon, rainfall and severe failure gradationally increases. This causes great casualties and serious damages to our parcels and terrain. For agriculture, the

extreme rainfall also makes the growth of crops unstable, and the problem of food deficit therefore becomes further and more serious. For all countries in the world, the food extremity has also come a veritably important issue.

Until now, most crops are still planted in the out-of-door. This means the growth of crops will be affected by the rainfall fluently. This also makes the yield and quality of ranch crops unstable. compared to the opening planting surroundings, lately, the hothouse becomes a new volition due to its controllable advantage with the incoming of agriculture 4.0, new ways similar as Cyber Physical Systems (CPS) and Internet-Of-effects (IOT) further enhance the effectiveness of the associate editor coordinating the review of this handwriting and approving it for publication was Mario Donato Marino the agrarian operation.

More with the fashionability of big data analytics, the trend of crop growth can be prognosticated and anatomized. For Example, by applying detectors the planting terrain of crops, the collected data can be farther anatomized to ameliorate the productivity and quality of crops. likewise, the corresponding selectors similar as sprinklers can be also controlled to interact with the physical world to insure the healthy growth of crops.

EXISTING SYSTEM

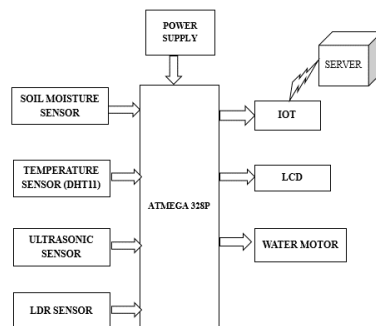

This paper aims at bridging this gap by using the technological advancements efficiently. Arduino is a platform that's of opensource nature and is one of the most habituated tools in electronics. It makes the conception of the interfacing of tackle a software, veritably readily. It can be integrated with all type of detectors and process information.

Due to their simple and accessible stoner experience, all Arduino bias is used for all major operations without any difficulties. Home robotization, Smart metropolises, smart metering, Security and exigency, Smart husbandry are among the many. Arduino is the main block of this proposed system as it's the MCU of the system. It's movable, easy to use. GSM is an important block as it will transfer the gathered data to the entering end (wireless).

Environmental conditions will affect the overall yield of the crop. shops bear specific conditions for optimal growth and health, covering the condition of the crop is necessary so detectors are used. Temperature and moisture detector – DHT- 11 is used for seeing the temperature and moisture of the girding crop so that it can be covered duly.

PROPOSED SYSTEM

The proposed Smart Crop Growth Monitoring System is a sophisticated agricultural solution that leverages cutting-edge technologies to optimize crop management. The system integrates System Adaptivity and Edge AI to ensure precise care for crops. Here's how each 33 component contributes to the system's functionality such as Ultrasonic Sensor to detects the height of plants. This information is crucial for monitoring the growth progress and determining optimal irrigation levels. Helps in adjusting watering schedules based on the height of the plants, ensuring they receive adequate moisture. DHT11 Sensor to measures room temperature, which is a vital environmental parameter for plant growth. Enables the system to adapt irrigation schedules based on temperature variations, ensuring optimal conditions for plant health. Water Motor to acts as the mechanism for irrigation, controlling the flow of water to the plants. Operates based on input from the other sensors to provide precise and timely watering, conserving water resources while ensuring plant hydration. Moisture Sensor to monitors soil moisture levels, a critical factor for plant health and growth. Guides the irrigation process, ensuring that plants receive the appropriate amount of water based on real-time moisture data. LDR Sensor to measures light intensity to distinguish between day and night periods. LCD Display to provides a visual interface for farmers to view real-time data and system status. Enables easy monitoring of sensor readings and system operations, allowing for quick intervention if needed. Edge AI to performs real-time data processing directly at the source, reducing latency and dependency on external computational resources. Analyses sensor data to make adaptive decisions, ensuring crops receive customized care for optimal growth.

Architecture of Smart Crop Growth Monitoring Based on System Adaptivity and Edge AI

HARDWARE DESCRIPTION

ARDUINO

Arduino / Genuino Uno is a microcontroller board based on the ATmega328P. It has 14 digital input / output pins (of which 6 can be used as PWM labors), 6 analog inputs, a 16 MHz quartz demitasse, a USB connection, a power jack, an ICSP title and a reset button. It contains everything demanded to support the microcontroller; simply connect it to a computer with a USB string or power it with an AC-to-DC appendage or battery to get started. The Uno board is the first in a series of USB Arduino boards, and the reference model for the Arduino platform; for an expansive list of current, once or outdated boards see the Arduino indicator of boards. The Figure4.1 shown is the Uno board is the first in a series of USB Arduino boards, and the reference model for the Arduino platform; for an expansive list of current, once or outdated boards see the Arduino indicator of boards.

TEMPERATURE SENSOR

The digital temperature and moisture detector DHT11 is a compound detector that contains a calibrated digital signal affair of temperature and moisture. These detectors serve grounded on colorful principles similar as resistance, voltage, or infrared technology. Common types include thermocouples, resistance temperature sensors (RTDs), thermistors, and infrared detectors. Thermocouples induce a voltage commensurable to temperature changes, while RTDs and thermistors alter their resistance with temperature variations. In discrepancy, infrared detectors descry temperature ever by measuring infrared radiation emitted by an object. These detectors find wide operation in different fields, including artificial systems, automotive technology, home appliances, healthcare bias, and environmental monitoring.

Soil Moisture Temperature

A soil humidity detector is an electronic device designed to measure the water content or humidity position in the soil. Soil humidity detectors are technical bias used to measure the humidity content in soil. TDR detectors dissect the time taken for an electromagnetic palpitation to travel through the soil, relating it with soil humidity content. Soil humidity detectors play a pivotal part in agriculture, enabling growers and gardeners to optimize irrigation schedules, help overwatering or underwatering, and enhance crop yield by icing

shops admit an applicable quantum of water for their growth. They grease effective water operation practices, conserving coffers and promoting sustainable agriculture ways.

LCD unit

It's a flat panel display, electronic visual display, or videotape display that uses the light modulating parcels of liquid chargers. An TV (Liquid Crystal Display) unit is a type of flat-panel display technology extensively used for visual affair in colorful electronic bias. It consists of a grid of liquid demitasse motes placed between two concentrated glass pollutants.

ESP8266

The NodeMCU (Node MicroController Unit) is an open-source software and hardware development environment built around an inexpensive System-on-a-Chip (SoC) called the ESP8266. The ESP8266, designed and manufactured by Espressif Systems, contains the crucial elements of a computer: CPU, RAM, networking (WiFi), and even a modern operating system and SDK. That makes it an excellent choice for Internet of Things (IoT) projects of all kinds.

However, as a chip, the ESP8266 is also hard to access and use. You must solder wires, with the appropriate analog voltage, to its pins for the simplest tasks such as powering it on or sending a keystroke to the “computer” on the chip. You also have to program it in low-level machine instructions that can be interpreted by the chip hardware. This level of integration is not a problem using the ESP8266 as an embedded controller chip in mass-produced electronics. It is a huge burden for hobbyists, hackers, or students who want to experiment with it in their own IoT projects.

LDR SENSOR

An LDR sensor, or Light Dependent Resistor sensor, is a type of passive electronic component that changes its resistance in response to changes in light intensity. An LDR (Light Dependent Resistor) sensor, also known as a photoresistor, is an electronic component that changes its resistance based on the intensity of light incident upon it. This sensor comprises a semiconductor material whose conductivity varies with light levels. When exposed to light, the resistance of the LDR decreases, allowing more current to flow through it; conversely, in darkness, its resistance increases, restricting the current flow.

WATER MOTOR

A water motor, also known as a water-powered motor or hydraulic motor, is a mechanical device that converts the energy of flowing water into mechanical energy, which can then be used to perform various types of work.

SOFTWARE REQUIREMENTS

ARDUINO IDE

Arduino IDE is opensource software that's substantially used for writing and collecting the law into the Arduino Module. It's sanctioned Arduino software, making law compendium too easy that indeed a common person with no previous specialized knowledge can get their bases wet with the literacy process. It's fluently available for operating systems like MAC, Windows and Linux and runs on the Java Platform that comes with inbuilt functions and commands that play a vital part for debugging, editing and collecting the law in the terrain.

A range of Arduino modules available including Arduino Uno, Arduino Mega, and Arduino Leonardo. The main law, also known as a sketch, created on the IDE platform will eventually induce a Hex train which is also transferred and uploaded in the regulator on the board. The IDE terrain substantially contains two introductory corridor Editor and Compiler where former is used for writing the needed law and latterly is used for collecting and uploading the law into the given Arduino Module. The Arduino Software (IDE) uses the conception of a sketchbook a standard place to store your programs (or sketches).

The sketches in your sketchbook can be opened from the train> Sketchbook menu or from the Open button on the toolbar. The first time you run the Arduino software, it'll automatically produce a directory for your sketchbook. You can view or change the position of the sketchbook position from with the Preferences dialog. Beginning with interpretation 1.0, lines are saved with an ino train extension. former performances use the .pde extension. You may still open .pde named lines in interpretation 1.0 and latterly, the software will automatically brand the extension to. ino. Programs written using Arduino Software (IDE) are called sketches. These sketches are written in the textbook editor and are saved with the train extension.

The editor has features for slice / pasting and for searching / replacing text. The communication area gives feedback while saving and exporting and also displays errors. The press displays textbook affair by the Arduino Software (IDE), including complete error dispatches and other information. The nethermost right-hand corner of the window displays the configured board and periodical harborage. The toolbar buttons allow you to corroborate and upload programs, produce, open, and save sketches, and open the periodical examiner.

CONCLUSION

In conclusion, the presented research offers a groundbreaking solution to the pressing challenges in agriculture by introducing a novel approach to crop growth monitoring. By seamlessly integrating system adaptivity and edge Artificial Intelligence (AI) technologies, our proposed system marks a significant leap forward in addressing the ever-increasing demand for enhanced crop yield, quality, and resource efficiency.

Traditional methods of crop monitoring often grapple with centralized data processing issues, such as latency concerns, data security vulnerabilities, and elevated operational costs. In stark contrast, our innovative system leverages a combination of cutting-edge sensors, edge computing, and AI algorithms to enable real-time monitoring and analysis of crop growth. The utilization of edge AI directly at the source mitigates latency problems and

ensures stringent data privacy, addressing critical drawbacks associated with conventional monitoring techniques.

Furthermore, the adaptability of our system is a key distinguishing feature. Through a sophisticated smart system management mechanism, cryptographic functions dynamically adjust based on security needs and resource constraints. This ensures that sensitive sensor data remains secure without compromising system performance or energy efficiency.

In essence, this research not only introduces a technologically advanced solution for crop monitoring but also underscores the importance of adaptability and efficiency in addressing the complex and evolving demands of agriculture. By embracing a holistic approach that combines cutting-edge technologies, our proposed system holds the promise of revolutionizing the agricultural landscape, contributing significantly to sustainable and resource-efficient crop production in the future.

RESULT AND DISCUSSION

RESULT

The implementation of the proposed system yielded promising outcomes in crop growth monitoring. Through the integration of advanced sensors, edge computing, and AI algorithms, real-time data collection and analysis were achieved, providing a comprehensive understanding of the crops' developmental stages. The utilization of edge AI significantly reduced latency, allowing for quicker decision-making processes crucial for agricultural management.

The adaptability of the system was evident in its dynamic adjustment of cryptographic functions based on security requirements and resource constraints. This ensured robust protection of sensitive sensor data without compromising the system's overall performance. The results demonstrated the system's efficacy in maintaining data security while optimizing energy efficiency, a critical aspect for sustainable agricultural practices.

DISCUSSION

The integration of system adaptivity and edge AI presents a paradigm shift in crop growth monitoring. Traditional centralized approaches often encounter challenges related to data processing delays and security vulnerabilities. In contrast, our system's decentralized

approach enhances efficiency by processing data directly at the source. This not only reduces latency but also addresses concerns surrounding data security, an imperative consideration in modern agriculture.

The dynamic adjustment of cryptographic functions emerged as a key feature in enhancing the system's adaptability. This mechanism ensures that the system remains resilient to evolving security threats while efficiently utilizing available resources. The discussion highlights the importance of this adaptive approach in balancing the often-competing demands of security and operational efficiency.

Furthermore, the successful implementation of the proposed system underscores its potential to revolutionize agricultural practices. Real-time monitoring facilitates timely interventions, optimizing resource usage and crop yield. The amalgamation of technology and adaptability positions this system as a robust solution to meet the contemporary challenges faced by the agricultural sector, ensuring sustainable and efficient crop production in the face of increasing global demands.

ABSTRACT

Conventional infant checking frameworks offer constrained functionalities, frequently centering on sound or visual observing. This unique investigates the potential of coordination Internet of Things (IoT) and facial acknowledgment to make a more comprehensive checking arrangement. By joining IoT sensors, the framework can assemble real-time information on imperative natural components like temperature and mugginess. Furthermore, it can screen sounds like crying, giving prompt cautions to guardians. Facial acknowledgment innovation includes a unused measurement, empowering the distinguishing proof of authorized caregivers entering the nursery. This will trigger notices and possibly discourage unauthorized people, upgrading the baby's security. In any case, executing facial acknowledgment in a child checking framework requires cautious thought. Addressing security concerns around information collection and capacity is fundamental. Vigorous security measures are basic to protect delicate child data and anticipate potential breaches.

INTRODUCTION

In spite of the fact that there's potential for more noteworthy mindfulness much appreciated to this innovation, it is imperative to consider security concerns and make

beyond any doubt that solid security measures are in put to secure touchy newborn child information. Innovative advancements have made it conceivable to track a baby's prosperity with modern innovations. One strategy coordinating facial acknowledgment with the Web of Things (IoT). IoT gadgets, such as cameras and sensors, are able to screen temperature and stickiness as well as distinguish sounds, such as sobbing. Another layer is included by facial acknowledgment, which has the capacity to recognize affirmed caregivers and inform parents of outsiders within the nursery. he assets open to parents to guarantee their child's prosperity development at the side innovation. Whereas families have benefited incredibly from conventional sound and video checking systems for a long time, advancements in facial recognition and the Web of Things (IoT) offer a see into long-standing time of newborn child observing. With the assistance of this imaginative arrangement, physical objects and sensors may be associated to the web to supply a more intensive checking involvement. Keenly situated Web of Things (IoT) sensors within the nursery can collect information in real-time on temperature, stickiness, and indeed discuss quality. This data offers smart data about possible causes of distress that will influence the baby's quality of rest and generally health. In expansion to observing the environment, the framework can utilize amplifiers to recognize sounds like sobbing and give notices to guardians smartphone's This makes it conceivable to reply to the baby's prerequisites right absent and mediate instantly. An additional degree of assurance is given by facial acknowledgment innovation. In an exertion to progress the baby's security, endorsed caregivers entering the nursery can be recognized, sending alarms to the guardians and possibly discouraging unauthorized individuals. But there are a few things to require into consideration some time recently coordination confront acknowledgment into a infant observing framework. The gathering and conservation of the baby's confront information raises genuine protection concerns. Solid security conventions are fundamental to ensure sensitive information and halt conceivable interruptions.

LITERATURE SURVEY

“Development of an IoT based Smart Baby Monitoring System with Face Recognition”(paper 1) Authors: Riasat Khan, Ahnaf Tahmid Ridwan.

People have a very busy and hectic life; thus, taking care of an infant constantly is tough. Especially for working parents, a modernized IoT-enabled baby management system will be

beneficial. In these modern times, most children are taken care of by their grandparents, housemaids, or babysitters during the daytime. In this work, we are using a very efficient and user-friendly technology to implement automatic swinging of the baby bassinet with sound detection of the baby crying using sound sensor and playing lullaby through speakers. The humidity sensor has been used to

know the diaper's moisture level, and notifications have been sent to parents with certain conditions through mobile calls and text messages. A web page using HTML and CSS has been developed, where parents/guardians can supervise the baby in real-time. Finally, the system will

detect if the baby is in the cradle using the face recognition technique. This exciting feature is implemented by using a Raspberry Pi 4 (Model B), which is equipped with a Pi camera that will also offer the parents a live-stream option. The proposed baby monitoring system is believed to be an improved technology for new and working parents and colossal help and riddance of non-required tensions.

"IoT-BBMS

internet of things-based baby monitoring system for smart cradle"(paper 2) Authors: W. A. Jabbar, H. K. Shang, S. N. I. S. Hamid, A. A. Almohammed, R. M. Ramli and M. A. H. Ali. The current number of working moms has enormously expanded. Hence, child care has ended up a day by day challenge for numerous families. In this way, most guardians send their babies to their grandparents' house or to infant care houses. In any case, the guardians cannot ceaselessly screen their babies' conditions either in typical or irregular circumstances. Hence, a Web of Things-based Infant Observing Framework (IoT-BBMS) is proposed as an proficient and low-cost IoT-based framework for observing in genuine time. We too proposed a unused calculation for our framework that plays a key part in giving way better child care while guardians are absent. Within the planned framework, Hub Micro-Controller Unit (NodeMCU) Controller Board is misused to assemble the information perused by the sensors and transferred by means of Wi-Fi to the AdaFruit MQTT server. The proposed framework abuses sensors to screen the baby's imperative parameters, such as surrounding temperature, dampness, and crying. A model of the proposed infant support has been outlined utilizing Nx Siemens program, and a ruddy meranti wood is utilized as the fabric for the support. The framework engineering consists of a child support that will naturally

swing employing a engine when the child cries. Guardians can too screen their babies' condition through an outside web camera and switch on the bedtime song toy found on the child support remotely through the MQTT server to engage the child. The proposed framework model is manufactured and tried to demonstrate its adequacy in terms of fetched and effortlessness and to guarantee secure operation to empower the baby-parenting anyplace and anytime through the arrange. At last, the child checking framework is demonstrated to work viably in checking the baby's circumstance and encompassing conditions concurring to the model.

“IoT based smart cradle system with an android app for baby monitoring”(paper 3)

Authors: M. P. Joshi and D. C. Mehetre

Availability of high speed internet and wide use of mobile phones leads to gain the popularity to IoT. One such important concept of the same is the use of mobile phones by working parents to watch the activities of baby while babysitting. This paper presents the design of Smart Cradle which supports such video monitoring. This cradle swings automatically on detection of baby cry sound. Also

it activates buzzer and gives alerts on phone if-first, baby cry continues till specific time which means now cradle cannot handle baby and baby needs personal attention and second, if the mattress in the cradle is wet. This cradle has an automatic rotating toy for baby's entertainment which will reduce the baby cry possibility.

EXISTING SYSTEM

Customary Newborn child Observing Frameworks: Advertising Fundamental Peace of Intellect To keep an eye (or ear) on their children, guardians have been depending on ordinary child observing frameworks for decades. For numerous families, these frameworks give a clear and down to earth arrangement, indeed in spite of the fact that they do not have the advanced capabilities of more later innovations. Center Highlights: There are two fundamental sorts of conventional child screens accessible: Sound screens: These are made comprising of a transmitter that's put within the baby's room and takes up sounds, sending them to a distinctive recipient unit that features a speaker. By tuning in to their infant's cries, coos, or developments, guardians can survey whether their child needs care. Video screens: These gadgets give a visual component. A camera within the nursery nourishes real-time

video to a devoted screen or versatile app. Guardians can not as it were listen their infant but too watch their action, breathing designs, and in general well-being. Ease of Utilize: A critical advantage of conventional screens is their user-friendly nature. Setting them up ordinarily includes negligible specialized mastery. Numerous interface through promptly accessible highlights like Wi-Fi or Bluetooth, making them open to a broader extend of clients. Cost-Effectiveness: Compared to progressed checking frameworks that join extra highlights and functionalities, conventional alternatives are by and large more reasonable. This makes them a budget-friendly choice for numerous families looking for a essential level of checking. Restrictions: Whereas advertising a sense of security, conventional frameworks have inborn impediments: Constrained Data: They essentially center on a single angle - sound or video. They cannot monitor crucial natural factors like room temperature or stickiness.

PROPOSED SYSTEM

The child cradle's utility and security viewpoints are moved forward by this imaginative concept, which cleverly coordinating a complex electronic setup into it. The ESP32 microcontroller, found at the center of the support, is dependable for planning a organize of sensors and actuators that are expecting to secure the infant and make them comfortable. Located inside the sensor cluster could be a movement sensor that's able to choose up indeed the littlest development made by the infant, giving caretakers prompt input. Caretakers are ensured from pain by the dampness sensor, which cautions of any wetness within the support environment. The DHT11 sensor, on the other hand, closely screens temperature and mugginess levels to form beyond any doubt the newborn child is comfortable and healthy. =

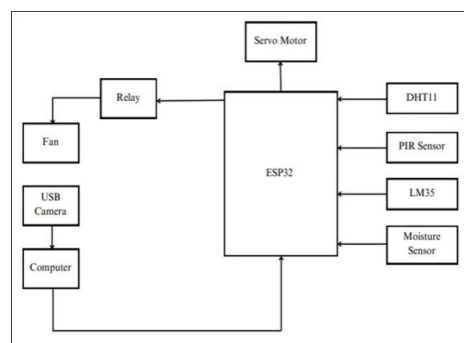

Figure 1 Block Diagram

With a GSM module introduced, caregivers can remain in consistent contact with the infant and get real-time status overhauls or cautions, no matter where they are. Parents may screen their child's prosperity indeed when they are not physically display much obliged to this farther network, which gives them piece of intellect. Additionally, the camera offers visual consolation by empowering guardians to outwardly check on their child at any time, and the temperature sensor includes an additional degree of assurance by making beyond any doubt t not one or the other as well hot nor as well cold. The baby's heart rate or beat is followed by the beat sensor, which extends on the checking scope by advertising significant information for the early distinguishing proof of any wellbeing issues. In the interim, the newborn child is made a difference to unwind and drop snoozing by the servo engine, which tenderly rocks the support in a rhythm that mimics the calming touch of a caregiver. To guarantee that the newborn child rests in a secure and secure environment, the beat infrared sensor advance makes strides security by seeing any startling nearness near to the cradle.

HARDWARE COMPONENTS

ESP32 MICROCONTROLLER

Figure 2 ESP32 Microcontroller

The quality and flexibility of Espress on the off chance that Systems' ESP32 microcontroller make it an extraordinary apparatus for wearables, implanted frameworks, and the Web of Things. With two Xtensa LX6 centers clocked at up to 240MHz, its dual-core CPU design empowers smooth multitasking and successful.

Dealing with of a assortment of workloads. The ESP32 exceeds expectations in communication in expansion to computing control, supporting Bluetooth 4.2, counting Bluetooth Moo Vitality (BLE), and 802.11 b/g/n Wi-Fi measures. This combination empowers communication with a wide run of Bluetooth-enabled gadgets and smooth

integration with remote systems. The ESP32 includes a wide run of fringe interfacing, such as SPI, I2C, UART, I2S, PWM, ADC, DAC, and GPIOs, to upgrade its association suite.

Various applications are made conceivable by these interfacing, which empower smooth communication with a wide run of sensors, actuators, shows, and other fringe gadgets. Besides, the microcontroller is prepared with solid security capabilities that ensure information keenness and secrecy in Web of Things organizations, counting secure boot, streak encryption, and cryptographic quickening agents. It too gives a extend of low-power modes that optimize vitality utilization for battery-powered and energy-saving applications. As a foundation of microcontroller innovation, the ESP32 is basically a extraordinary choice for designers and engineers looking to realize cutting-edge IoT, wearable, and implanted arrangements since it gives a compelling combination of preparing control, network, fringe flexibility, security, and vitality proficiency.

PIR SENSOR

A PIR sensor, which stands for Inactive Infrared Sensor, may be a key component in a few child screens. It identifies changes in infrared radiation, which is basically warm. Within the setting of a child screen, the PIR sensor is searching for warm emanating from the child. When the child moves around in their lodging, their body warm will cause changes within the infrared radiation levels. The PIR sensor picks up on these changes and sends a flag to the infant screen. The screen can at that point alarm guardians that the infant is wakeful or moving around. This permits parents to check on their infant without requiring to physically enter the nursery each time they listen a clamor or suspect the infant may well be wakeful. It's imperative to note that PIR sensors aren't culminate. They can be activated by other things that radiate infrared radiation, like pets or changes in room temperature. For a more total picture of what's going on within the bunk, a few child screens combine PIR sensors with amplifiers o distinguish sound as well.

MOISTURE SENSOR

In a infant observing framework, a dampness sensor doesn't straightforwardly identify dampness within the discuss like a mugginess sensor. Instep, it's particularly planned to distinguish wetness on the baby's bedding. Typically vital since damp diapers or spit-up can cause inconvenience for the baby and possibly lead to skin disturbance.

Figure 3 Moisture sensor

The sensor may be a conductive cushion put beneath the sleeping cushion or a pressure-sensitive tangle that identifies changes when the bedding gets to be damp. When the sensor identifies dampness, it triggers an caution on the child screen, informing the parent that it's time for a diaper alter or to check on the child. This permits for provoke consideration to the baby's needs and makes a difference keep up a clean and comfortable resting environment.

SERVO MOTOR

A servo engine may be a little but effective engine that can be absolutely controlled to turn a particular point. In a infant screen, a servo engine may be used to remotely dish and tilt the camera unit. This would permit guardians to induce distant better; a much better; a higher; a stronger; an improved">a much better see of the nursery from the screen itself, without requiring to physically alter the camera. Envision being able to look in from your phone to see in the event that the child is fussy or fair reposition the camera for a clearer see in case something appears out of order. Whereas not basic, servo engines give an additional layer of comfort and control for guardians employing a camera-equipped infant screen.

Figure 4 Servo Motor

LM35 TEMPERATURE SENSOR

The LM35 temperature sensor plays a basic part in guaranteeing your baby's consolation and security inside a child checking framework. Not at all like the DHT11 sensor which gives both temperature and stickiness readings, the LM35 exceeds expectations at absolutely measuring discuss temperature. This small sensor persistently screens the room's temperature, sending information to the infant screen. With this data, guardians can guarantee their child rests in a secure and comfortable

environment. In case the room gets as well hot or as well cold, the screen can trigger an caution, inciting you to alter the indoor regulator appropriately. This makes a difference avoid overheating, which can be unsafe for babies, and chills that might disturb their rest. By keeping a near eye on room temperature with the LM35 sensor, you'll be able make an perfect resting environment for your infant, permitting for tranquil rest and peace of intellect for you.

Figure 5 LM35 Temperature Sensor

PULSE SENSOR

Whereas unprecedented in commonplace child screens due to security concerns, beat sensors offer a possibly profitable work. A beat sensor, frequently utilizing infrared light innovation, can identify changes in blood stream close the skin's surface. In hypothesis, it might be coordinates into a infant screen to track a baby's heart rate. Be that as it may, there are restrictions. Firstly, it wouldn't give a medical-grade perusing. Besides, legitimate arrangement on a squirming child can be challenging. Most critically, there's a hazard of wrong cautions due to sensor development or outside components. For these reasons, beat sensors aren't right now a standard highlight. The center remains on guaranteeing a secure environment through temperature and development observing, clearing out restorative evaluations to qualified experts.

SOFTWARE COMPONENTS

BLYNK APP

This app serves as a convenient user interface for parents. It displays sensor data such as temperature and heart rate and may provide controls for various system features. It allows remote monitoring from a smartphone or tablet.

ARDUINO IDE

The development environment for programming the ESP32 microcontroller. You'll write the code that reads the sensors, processes the data, controls the servo motor, sets up SMS alerts, and communicates with the Blynk app.

BLYNK LIBRARIES

Libraries for the Blynk app will streamline the communication process between the app and the ESP32.

Facial Expression Recognition Library:

If included, a library like OpenCV enables the analysis of the images captured by the camera to understand the baby's emotional state.

Programming Language for AI Analysis:

If you're doing advanced AI-based analysis of the baby's facial expressions, you'll need a suitable programming language and libraries.

HARDWARE IMPLEMENTATION

SENSOR DATA ACQUISITION

This inactive infrared (PIR) sensor recognizes changes in infrared radiation transmitted by objects. When the infant enters or takes off the support, their body temperature change causes a alter within the identified radiation. The ESP32 peruses this alter in flag, demonstrating the baby's nearness or nonappearance. Dampness sensor frequently utilizing resistive properties, recognizes varieties in electrical resistance based on dampness levels. When the support lining gets to be damp due to diaper changes, the resistance between the sensor's cathodes diminishes. The ESP32 recognizes this alter and triggers an SMS alarm. beat sensor ordinarily employments photoplethysmography (PPG) to degree heart rate. It radiates light onto the baby's finger or ear cartilage. As blood pumps through the tissue, there are slight varieties in light assimilation. The ESP32 recognizes these vacillations and calculates the baby's heart rate. This analog sensor yields a voltage relative to the encompassing temperature. The ESP32 has built-in analog-to-digital change (ADC) capabilities. It changes over the sensor's voltage yield into a computerized esteem speaking to the room temperature.

DATA PROCESSING AND ANALYSIS

The ESP32 translates the alter within the PIR sensor flag. In the event that the flag shows development inside the cradle's extend, it can trigger an activity like upgrading the Blynk app with a notice that the child is present.

Figure 8 Sensor Connectivity on Project

Upon identifying a critical diminish in resistance from the dampness sensor, the ESP32 can start an SMS caution sending module. This pre-programmed module would be arranged with the parents' phone numbers and a pre-defined message like "Diaper alter caution!". The ESP32 changes over the crude PPG flag varieties from the beat sensor into a advanced arrange. It at that point calculates the interims between these crests to decide the baby's heart rate in beats per miniature (bpm). This data is shown on the Blynk app. The ESP32's ADC changes over the LM35 sensor's voltage yield into a advanced temperature esteem. This esteem is at that point changed over to a recognizable unit like degrees Celsius or Fahrenheit utilizing fitting transformation components inside the code. The temperature is shown on the Blynk app. Captured pictures can be shown on the Blynk app for real-time observing, or put away on an SD card or cloud capacity for afterward investigation.

Figure 9 Prototype of the Project

AUTOMATED RESPONSES

The ESP32 can have a built-in mouthpiece or utilize an outside one. By analyzing the sound for particular cry designs, the ESP32 can trigger the servo engine to delicately shake the support at a pre-programmed speed and term. Then again, cloud-based administrations with more progressed sound investigation capabilities can be coordinates for cry discovery and activating the shaking reaction.

Figure 10 Blynk App Functionality

The sensors connection is shown in figure 6.4. PIR sensor is used to detect the motion of the baby. If the baby in the cradle makes any movement then it sends the email notification to the mobile. Moisture sensor is used to detect the wetness. When the wetness is detected, it sends notification to the mail. The above figure 6.5 displays the mail received from the Blynk app using the machine learning code. The Blynk app detects baby status and gives updates through mail. If the baby is sad, then it sends notification and trigger the servo motor after that cradle will produce smooth oscillation.

CONCLUSION

A summary of the advantages of infant monitoring using IoT . The significance of confronting obstacles and constraints. Possibility of further developments in the realm of

facial recognition and IoT-based infant monitoring. Our study shows how several sensors, AI, and automation can be successfully integrated to build a responsive and intelligent infant monitoring system. Talk about the precise outcomes in terms of user input, automation efficacy, and sensor accuracy. Emphasize the project's accomplishment of its goal and the advantages it may have for new parents and babies. Examine the system's shortcomings, such as the requirement for manual calibration or possible false positives. Talk about possible improvements in the future.

Including more sensors, such as an air quality sensor and a CO2 monitor, putting complex AI features into practice, such as anomaly detection and sleep cycle analysis.

enhancing the Blynk app's user experience and data presentation. Taking privacy and data security into account.

FUTURE SCOPE

It offers a robust foundation for future expansion and innovation. With its blend of IoT connectivity and facial recognition capabilities, the system can evolve to incorporate advanced features and address emerging needs in baby monitoring and home automation. There is potential for integration with smart home ecosystems, incorporation of environmental sensors for comprehensive monitoring, and implementation of machine learning techniques for behavior analysis. As the project continues to evolve, it holds promise for providing caregivers with even greater insights, convenience, and peace of mind in monitoring their infants' well-being. Beyond its immediate purpose of enhancing baby monitoring by integrating IoT devices and facial recognition technology, it could evolve to address broader needs in childcare and home security. Future iterations might incorporate additional features like environmental sensors for temperature and air quality monitoring, real-time alerts for parents, and integration with smart home systems for seamless automation. Moreover, as facial recognition technology continues to advance, the system could expand to offer personalized interactions and adaptive functionalities tailored to each child's developmental stage. With the growing demand for smart home solutions and childcare innovations, this project stands poised for continued expansion and refinement in the ever-evolving landscape of IoT and AI technologies.

ABSTRACT

This conference paper presents a Smart Electric Vehicle (EV) Station and EV Battery Monitoring System, an innovative project that combines Internet of Things (IoT) technology to create a comprehensive and efficient solution for electric vehicle charging infrastructure. The system enhances user experience, ensures security, and provides real-time monitoring of EV battery health. The EV station incorporates an automatic gate system that opens and closes upon vehicle entry, optimizing security and user convenience. To streamline parking management, the system employs a slot availability counter, allowing users to check the availability of parking spaces through the Blynk IoT cloud platform from anywhere in the world. This feature promotes efficient space utilization and enhances the overall accessibility of the EV station. The battery monitoring system is a critical component, ensuring the health and safety of EV batteries. Through an OLED display, users can locally monitor the battery percentage, temperature, and humidity. Additionally, this information is accessible globally through the Blynk IoT cloud, enabling users to remotely check the status of their EV batteries. Users receive email notifications when the battery percentage is low or when the battery temperature exceeds predefined thresholds. This proactive alert system ensures that users stay informed about their EV battery status, allowing for timely actions to be taken, such as charging the vehicle or

addressing temperature concerns. By providing real-time information and alerts, this system empowers users to make informed decisions, ultimately fostering a more efficient and reliable electric vehicle charging infrastructure.

ABSTRACT

With the advent of sophisticated yet easy to use video editing and forgery tools, detection of malicious editing and forgery in digital videos is becoming increasingly challenging as development of forensic investigation tools for authenticating the integrity of digital videos has lagged behind. The work reported in thesis explores four novel methods aimed towards detecting object and facial forgeries in video: temporal-RNN, spatial-RNN, fRNN, and lightweight 3DRNN.

The temporal-RNN and spatial-RNN methods are designed for comprehensive detection of object-based forgeries. They analyse temporal and spatial features within a video in order to detect forged frames within a video and to mark forged regions within forged frames. The benefits of proposed detectors were exhaustively verified using recent object based forged video datasets under various testing scenarios. Significant improvements in detection performance and forged region localization were observed in comparison to existing detection methods.

A frequency-based RNN is developed to identify facially manipulated videos (such as Deep Fakes, Face Swap and Face2Face). The shallow fRNN architecture was verified for binary and multi-class forgery detection on recent datasets. The fRNN was also benchmarked on the FaceForensics++ platform and binary detection performance of fRNN was found to be better than existing machine learning and deep learning based detectors.

A lightweight 3DRNN is designed to detect the facially manipulated videos. The detector utilizes the combined effect of spatial and temporal features in a unique manner to label the given video as forged. The 3DRNN architecture ensures low computational complexity in terms of number of trainable parameters, making it a good choice for deployment in memory and resource constraint devices such as smartphones. The method

also performed well against low quality, highly compressed videos that are commonly found across social media.

INTRODUCTION

Now-a-days, the videos which are seen on flat LEDs, movie theaters, smartphones, laptops, etc. are digital videos. The digital videos are compressed using different codec techniques such as MPEG-2, MPEG-4, H.264[1], H.265[2], H.266[3] format etc. These digital videos are stored on dDrives and blu ray discs and thus can be easily ported anywhere. Most of the digital videos are easily captured from low end devices. This convenience is one of the important reasons why social sites are flooded with such low end device videos. However, the traditional videos which were seen on cathode ray tube systems televisions were captured with analog technology. These analog videos were stored on magnetic tapes and needed a bigger and heavier video cassette recorder to watch or port it.

But, analog videos are trustworthy when compared to digital videos. It requires robust and efficient hardware to perform any manipulations in an analog video. These analog manipulations are not only difficult to perform but also are easily visible and identifiable by human eye with precise observation. However, the digital videos are easily edited hence forged using generally available hardware and software. Thus lacks trustworthiness as compared to analog videos. The digital video editing softwares has grown by leaps and bounds regularly and have become super popular even among non-professionals because of increased accessibility to affordable hardware, ease of creating videos and availability of free editing softwares. The video-editing softwares are easily operated by common people also because of the extensive availability of tutorial videos on powerful platforms like youtube etc. for helping the users. Most recently designed smartphones have inbuilt simple video editing softwares such as filters to add special effects, enhance contrast and quality, join video clips, etc. However the operations such as adding motion effects, altering color graphics, trimming video clips, merging 1 video clips, etc. can

be performed by employing sophisticated video editing softwares. Moreover, with professional video editing tools seamless transition between the two different places can also be generated. The digital transition video clips are so clear that they actually appear to be at the same place. Recently deep learning networks are also used in video editing tools and applications.

Figure 1.1: Representing a frame from Talking Mona Lisa clip, Samsung AI research lab work [4], video adopted from github.

The developing deep learning networks have given the society an opportunity to enhance its creative side. These networks have an ability to generate new unseen data. This unique characteristic is exploited by innovators in various fields. The fashion industry is using deep learning to create new design patterns [5], musicians are utilizing it for composing music [6], the medical science is using the trained networks in diagnosis [7], civil engineers are constructing 3D models from images [8], generating videos from images [9] and many more. The famous example in the context of video generation is "Talking Mona Lisa" video clip.

The portrait of Mona Lisa becomes alive in the famous work of Samsung AI research lab, "Talking Mona Lisa". The figure 1.1 represents a frame from "Talking Mona Lisa" video clip. The figure shows moving head and lips of Mona Lisa. The work is inspired from Kim et al. [4]. The generative adversarial networks are employed to produce such creative video clips. These networks are trained on talking head datasets, which extract facial landmarks. These extracted landmarks are further mapped to the facial landmarks of the target face (publicly available portraits or facial images). This presents the best utilization of technology in driving the society

Figure 1.2: A left video frame represents a facially manipulated face of former US president Barack Obama, video adopted from [10]. The right video frame represents the original faces of former US president, which are learned by the expression reenactment method [10]. in creative and innovative manner. Similarly many video editing tools based on deep learning and machine learning are utilized to enhance the visual experience of user. On the other hand, the presence of such innovative technology has given rise to malicious usage in the society. The deep learning models are used to generate fake videos. The figure 1.2 represents a video frame from former US president's public addressing clip. The video clip is conveying the message which Mr. Obama had never spoke. This video clip is generated by employing the method designed in [10]. The model learned the target face lip movements from the videos and clips available on internet and reenacted to the synthetic audio. Another malicious usage of deep learning technology is DeepFakes, where identity of the person is swapped [11]. The sufficient amount of video clips / images and computation power is required to create fake videos where world leaders are confessing illegal activities, also in some videos military personals are stating racially insensitive information leading to civilians unrest. The famous business men are found claiming their profits going down in some videos leading to global stock manipulations. Moreover the developed editing softwares are also applied on surveillance videos to add or remove objects. All these synthetic and tampered videos are difficult to be identified by human visual system and require a robust and precise investigation. In addition to above, such malicious usage of editing tools and software applications have posed a threat to democracy and nations, also have seeded distrust in society. Therefore, special agencies were formed worldwide to check the integrity of videos and its broadcasting [12]. This precise investigation is conducted by video forensics departments of the countries and extensive research is conducted to develop robust fake video detectors.

RELATED WORK

In literature it was found that object based forged videos and facially manipulated videos are of prime concern to video forensic researchers. The object based forged videos are formed from manipulated surveillance camera videos. The videos are captured at ATMs, traffic signals, lift lobbies, public places, etc. and are tampered by inserting or removing the target object to mislead the evidence presented in the court of law.

The facially manipulated videos are generated utilizing computer graphics or deep learning methods. The popular facially manipulated videos are DeepFakes, FaceSwap and Face2Face. These videos result in fake news, deceiving election campaigning, altering video identity proof clips, defaming person's identity etc.

Researchers have detected these forged videos using statistical, machine learning and deep learning based methods. In following subsections the state-of-the-art object based video forgery and facial manipulation detectors are discussed in detail.

DEVELOPED OBJECT BASED FORGED VIDEO DETECTORS

The object based video forgery is a type of copy-move forgery. Generally the object based forgery is concealed by implementing inpainting algorithms (as described in [13], [14] and [15]).

The commonly employed copy-move or object based forged video datasets in literature are SULFA [16], GRIP [17], REWIND [18], [19] and SYSU-OBJFORG [20], and their cardinality is represented in figure 1.3 using pie-chart. However, there is another publicly available dataset of original videos from Xiph (derf's collection) [21], which consists of videos of variable resolutions (such as CIF, QCIF) and formats.

Jia et al. [22] in their work developed a copy-move video forgery detector. The detector was exploiting the features extracted from optical flow of a given video to label a video as forged. The detection method was tested on SULFA(320×240), VTL(352×288) in YUV format, DERF(176×144) in Y4M format copy-move video forgery datasets. The developed detector work with two levels, at the first level consistency in optical flow is evaluated to select the sus

Figure 2.1. A pie chart representing number of videos in popular copy-move forgery datasets, available in literature.

pected forgery position in video frames and at second level the duplicated frame pair matching algorithm followed by a false detection reduction algorithm is applied to label the exact forged frames in the given video. Jia et al. method was a frame level copy-move forgery detection. D'Avino et al. [23] developed video forgery detection method based on autoencoder and recursive neural network. The developed method trained autoencoder to learn to generate pristine frames. The trained autoencoder generate error or disturbed output when encountered with copy-moved or spliced forged frames. Consequently results in video forgery identification. The author also deployed LSTM to exploit the temporal dependency features of the given video to improve the developed method performance. The major advantage of the [23] method is that training process does not require forged videos. However the application of D'Avino et al. [23] is limited to frame level video forgery detection for low resolution youtube videos.

Johnston et al.[24] in their work utilized the features learned from pristine videos to detect forgery. The method employed RNN to estimate the compression parameters of a given video i.e. quantization parameter, intra (or inter) and deblock modes. These estimated compression parameters along with delta frames were utilized to locate the key frames in a given video. And subsequently the forged region was localized in the identified key frames using the information estimated through RNN. The method was trained on YUV format test video sequences of CIF and QCIF resolution videos for extracting compression parameters, tested for DERF(176×144) with copy-move video forgery and spliced videos of [23]. This method failed against variable 6 Group Of Picture (GOP) structure videos. Moreover it did not discuss how to localize forgery in the high resolution videos.

Chen et al. [20] developed a machine learning based forgery detection method. Their method exploited features of motion residuals to detect forged frames. The authors observed unique characteristic of motion residuals of forged frames in a given video and employed steganalytic feature extraction algorithms like SPAM, CCPEV, SRM etc. to generate the handcrafted feature sets. These feature sets are further processed to ensemble classifier to detect frame level forgery in a video. Moreover the authors improve forged frame detection accuracy by developing a fine tuned detection pipeline. The method works for static background videos and is limited to frame level forgery detection.

Zhang et al. [25] identified ghost shadows as the primary artefact to detect forgery in object based method. This was employed for low resolution videos. Hsu et al. [26] utilized temporal artifacts in a video. The authors determined the irregular correlations between forged video frames. The [25] and [26] are statistical approaches which are limited to specific videos. Another method developed in [27] detect the temporal copy-paste forged video by using the optical-flow features of the given video sequence. The method [27] is tested on low resolution SULFA videos [16].

Richao et al. [28] designed a video forgery detection by exploiting object contour features in the form of moments, gradients and other statistical parameters. These parameters were fed to Support Vector Machine (SVM) to classify the given video as forged or pristine. Another comprehensive sensing method designed by Lichao et al. [29] also detects and localizes video forgery. However the local performance drops for the small region which is forged and for fast moving forged videos. The [28] and [29] methods are applicable to static background videos with low resolution. The methods fail to detect forgery in advanced codec videos with variable GOP structures.

The forgery detection method presented in [30] identified object removal forgery performed by temporal copy paste method and exemplar-based texture method. The designed method captured spatio temporal features and analyzes them using statistical models. The designed method performance get affected for advanced codec videos i.e. videos compressed using MPEG-4, H.264, etc.

A patch match based method was designed in [31]. The method using patch matching analysis identify the forged region in forged video. The designed matching algorithm is computationally 7 expensive. The authors tested the designed method for resolution videos

with large duration forged segment. Therefore the method fails for videos with short duration forgery and have high resolution.

DEVELOPED FACIAL MANIPULATION DETECTORS

The forged videos where the face of the person is targeted to perform malicious alterations are called facially manipulated videos. These facially manipulated videos are extensively explored by researchers in recent years.

Figure 2.2: A pie chart representing number of forged videos in popular facially manipulated video datasets, available in literature.

To evaluate the designed detection models researchers utilize publicly available datasets. In literature various facially manipulated datasets are available. The mostly employed datasets are UADFV [33], DeepFakeTIMIT [34], FaceForensics++ [35] and Celeb-DF(v2) [36] and their cardinality is represented in figure 1.4 using pie-chart.

The UADFV dataset consists of only 98 videos, with 49 real and 49 fake [33]. This dataset is simple and easily detectable. DeepFakeTIMIT dataset consists of 620 forged videos. The dataset is derived from VidTIMIT dataset videos. This dataset has low quality and high quality compression videos. The DeepFake videos are generated using GAN models [34].

FaceForensics++ [35] is huge dataset with 4000 forged and 1000 pristine videos. The dataset consists of multiple facial forgeries such as DeepFakes, Face2Face, FaceSwap and Neural Textures. The Neural Textures is a GAN based expression swapping forgery. However, CelebDF(v2) [36] is celebrity based dataset of youtube videos with 590 pristine and 5639 DeepFakes videos. FaceForensics++ and Celeb-DF(v2) dataset are recent and versatile, which make these datasets popular among researchers.

Researchers utilized inconsistency in lip movements [10], color disparities in facial region [37], facial wrapping artifacts [38], eye blinking pattern [39], [40] to detect facially manipulated videos. In [41] authors utilized visual features from facial regions near eye, nose mouth or on facial contours. These facial features are processed through logistic regression models. These classification models utilizes the fine details of facial features as differentiating element between forged and pristine video.

However in [40] the authors focused only on the pattern of eye blink using statistical tools to decide whether the given video is facially manipulated or pristine. Similarly the authors in [39] deployed Deep Vision to identify disparities in eye blinking pattern. Researchers employed various facial expressions and visual artifacts to identify the manipulated videos. In [42], Tolosana et al. employed head movements extracted by land marking the facial points to separate the forged videos. Further, the authors deploy SVM classifier to detect synthetic videos. The designed method was tested on UADFV and FaceForensics++ and CelebDF dataset.

videos. In [42], Tolosana et al. employed head movements extracted by land marking the facial points to separate the forged videos. Further, the authors deploy SVM classifier to detect synthetic videos. The designed method was tested on UADFV and FaceForensics++ and CelebDF dataset.

Another detection approach based on facial expressions was discussed in [43]. The authors used different facial actions and facial muscle movements for examples checks, nose wrinkles, mouth movement etc. and moreover also include four especial head movements for extracting discriminant features and pass to SVM for classification. Similarly in [33], the detector focused on the inconsistency in the head pose of the synthetic faces to identify the forged videos. This method also employed machine learning algorithm for classification. The [42] either employed detection method cropped face and specific facial region in the video, however in [43] and [33] authors employed detection method on the face in the video.

Rosseler [35] generated a publicly available, huge and versatile facially manipulated forged 9 video dataset, named Face Forensics++. The generated dataset comprises facial forgeries such as Deep Fakes, Face Swap, Face2Face and Neural Textures. The authors presented a detection performance analysis of different machine learning and deep learning based forgery detectors. Xception Net [44] reported to perform best among all the detectors

discussed in the paper [35]. However, the implemented detectors achieved high detection accuracy at the cost of number of trainable parameters.

Afchar et al. [45] developed facial video forgery detection method for Deep Fakes and Face2Face. The authors designed two detection methods, the first one utilizes simple RNN architecture however the second one utilized inception model [46]. Both the designed methods perform good in detecting facially forged videos. Moreover authors also described the visualization technique to comprehend the activation maps of RNN and subsequently its classification criteria. This visualization technique is adopted in the thesis work to visualize and interpret the designed RNN models.

METHODOLOGY

INTRODUCTION

VIDEO FORGERY The live streaming or camera captured videos incorporating certain kind of artifacts due to various factors like background noise, poor illumination video acquisition process, etc. Moreover, some distortions incurs during compression and transmission process[58]. These artifacts effect the quality of video. Thus to enhance the video quality for clarity purpose various statistical, machine learning and deep learning based editing tools are used [59],[60], [61]. These editing tools alter the vital parameters of a video, like resolution, frame rate, contrast, luminance, etc., to provide users a good visual experience. With the recent technological developments, the video manipulations can be performed offline as well as online (during live video conferencing or chat video calls).

The video editing tools when used for malicious purposes, like tampering of evidence, generating fraud identity clips, broadcasting fake news etc., then these generated videos are termed as Forged Videos. The forged videos may defame a person's identity, misleading the court of law, deceive election campaigns and may seed distrust and disharmony in the society. The recent fake news about the Ukrainian president's speech where he was publicly addressing the troops to return from the border, is a good example to explain how the forged video affected the world politics and subsequently everyone's life. This leads to an urgent requirement to design and implement robust forgery detectors for video authentication.

TYPES OF DIGITAL VIDEO FORGERY

Several types of digital video forgeries are available in literature and are divided into three categories, namely inter-frame video forgery, intra-frame video forgery and facially manipulated videos. The figure 3.1 represents different categories of digital video forgery.

Figure 3.1: Types of digital video forgery

INTER-FRAME VIDEO FORGERY

In this type of digital video forgery, the temporal information of a video is manipulated i.e. the information or content stored in a frame or in consecutive frames is altered. This type of forgery is performed between the frames. The different inter-frame video forgeries are represented in figure 3.2.

To illustrate the inter-frame video forgery, sequence of eleven frames are selected from a video as shown in figure 3.2(a). The frame deletion, duplication, insertion and shuffling of frames are represented in figures 3.2(b) to 3.2(e) respectively and are described as follows:

Frame Deletion Forgery

In this type of forgery, the target frames are deleted from the video sequence. The figure

Figure 3.2: The inter-frame video forgery representation, figure adopted from [62]. (a) Original Video Frames (b)Frame Deletion Forgery (c)Frame Duplication Forgery (d)frame Insertion forgery and (e) Frame shuffling forgery

(b) depicts frame-deletion, where the frame numbers 4 and 6 are purposefully deleted from the video sequence.

Frame Insertion Forgery

The video forgery where frames intentionally added in the existing sequence frames to alter the content of video is termed as frame insertion forgery. The figure 3.2(d) illustrates the frame insertion forgery where the frames numbers marked in red i.e. F1 and F2 are inserted between the frame number 8 and 9. These F1 and F2 frames are either imported from another video or generated.

Frame Duplication Forgery

In this type of forgery, the frames are duplicated and inserted at random or at specific locations. The figure 3.2(c) represents the frame numbers 3, 4 and 5 are duplicated and 17 inserted at the place of frame 8, 9 and 10. The duplicated frames are marked in red coloured frame number in figure 3.2(c). The frame mirroring forgery described in [63] is also similar to frame duplication. In frame mirroring forgery the target frames are copied from video segment and pasted in its mirrored form at some other location in the same video. In literature frame duplication and frame mirroring is used as synonyms.

Frame Shuffling Forgery

The video forgery where the original sequence of frames are shuffled is termed as frame shuffling forgery. This forgery will alter the sequence of events occurring in the video. The figure 3.2(e) indicates the frame shuffling video forgery, where red marked frame numbers 5, 6, 9 and 10 are shuffled.

INTRA-FRAME VIDEO FORGERY

Figure 3.3: Representing the spliced video forgery, figure adopted from [62].

The digital video forgery where the spatial information of video is manipulated i.e. the information within the frame, is termed as intra-frame video forgery. In this type of forgery, the objects in frame are copy-moved or spliced to generate the fake frame and subsequently the fake video.

The intra-frame is broadly classified into two categories:

Splicing

The video splicing is performed at frame level, where to hide or alter the frame content the object or region within the frame or from other video frame is added to the original frame. The figure 3.3 illustrates the spliced video frame. The figure 3.3(a) shows the original video frame, figure 3.3(b) shows the video frame to be spliced and finally in figure 3.3(c) the two frames are combined to generate a fake video frame. This type of video forgery is similar to image splicing.

Figure 3.4: The copy-move forgery example (a) and (b) are pristine and forged video frames of REWIND dataset presenting object insertion copy-move forgery [16]. (c) and (d) are pristine and forged video frames of SYSU-OBJFORG dataset presenting object removal copy-move forgery [20].

Copy-Move Forgery

The copy-move video forgery is the most common forgery. In copy-move forgery, the forger copies the target object and paste it either on the same frame or on the other frame of same video. The motive behind the copy-move forgery is to hide the content in the frame or

duplicate a certain object. The figure 3.4(a) and (b) represent the pristine 19 and forged video frames from REWIND dataset [16] of copy-move videos. The pristine frames in figure 3.4(a) describes road scene. However, the forged frames in figure 3.4(b) describes the white car again passeing the camera. The forged frames show the copy-move forgery, where the target object (car) is inserted in the frame. The copy-move forgery is also termed as object based forgery.

OBJECT BASED VIDEO FORGERY

The object based video forgery is a type of copy-move forgery, where an object (person/thing) is intentionally removed or inserted in the frame to alter the conveyed message in a video. The forger remove or insert the target object from the particular frame and then to make the forgery undetectable cover the forged region with background. Thus the object based video forgery is copy-move forgery followed by inpainting.

The figure 3.4 presents the pristine and forged video frames of SYSU-OBJFORG dataset[20].

The figure 3.4(a) represents the pristine video frames and the figure 2.4(b) represents the forged frames.

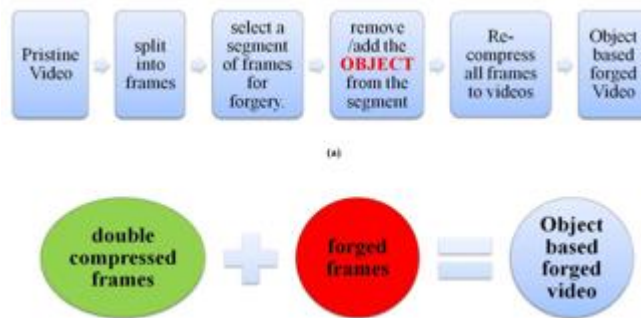

Figure 3.5: The flow diagram of object based forged video generation.

To generate a object based forged video, the given video is split into frames and then a segment of frames is selected to perform the forgery. From the selected segment of frames the target object is further chosen to be removed or inserted. After the removal or insertion of target 20 object, all the frames are re-compressed with the same previous coding algorithm or a new coding algorithm. These object based forgery steps are described in figure 3.5(a).

The important point to be noted is that, the frame re-compression process consists of both the untouched frames and forged frames. The untouched frames are compressed twice,

thus termed as double compressed frames while the frames from where objects are removed or inserted are termed as forged frames. The figure 3.5(b) is illustrating the generated object based forged video comprises of double compressed and forged frames.

FACIAL MANIPULATED VIDEOS

Figure 3.6: Representing the forged video frames of Celeb-DF dataset [36]. The facial manipulated videos are not new in the area of forged videos. The computer graphics based facial expression alterations are generally fabricated to create fake videos. However with the advancement of artificial intelligence based techniques, these facial manipulations are becoming easy to perform as well as more reliable and undetectable [36]. The facial manipulated videos are the videos, where the face of person is the target for the forger. The forger tamper the identity or the expressions of a person in a video to generate a fake video. These facially manipulated videos are illustrated in figure 3.6, a video frame of Celeb-DF dataset [36].

Expression based

The facial videos where the expressions of target person is manipulated to convey the false information. The example of expression based forgery is Face2Face [64]. 21

Identity based

The facial videos where the identity of the target person is swapped with another person or the new identity is generated using deep deep learning tools. The famous facial identity based video forgeries are DeepFakes [11] and FaceSwap [65].

FACE2FACE

The Face2Face is an expression based facial forgery. In this type of facial forgery, the expressions of a person are swapped with the expressions of another person. It consists of

altering the lip movements, marks on cheeks, chin, head etc. The expression based alterations are followed by audio mapping [64]. This results in a new artificial video which was never occurred in reality. The facial expression manipulation is also popularly called as facial reenactment. The authors in [66], [67], [68] and [69] work towards building an offline facial reenactment techniques which is generally employed in animations of video game avatars and in movies. However the method adopted in [64] work towards designing a real-time facial expression transfer. This real time facial reenactment technique can be employed to a video conferencing where the real-time face movements are mapped to the new foreign language. However the malicious usage of this real-time facial reenactment technique results in forged video generation.

The first pre-process video tracking stage comprises extracting the identity of target face. Further frame by frame tracking the given training video sequence is performed to extract information about expressions, pose and other peculiarities of a target face. The first step was performed offline on the given training sequence and therefore the geometrical ambiguities of target face were resolved by the Thies et al. method [64]. In second step, the online RGB tracking of target and source face was performed. The authors deploy a statistical approach of dense analysis-bysynthesis. In this step again identity, expression and other peculiarities are captured.

Finally a deformation transfer function [70] was utilized by Thies et al. [64] to map the expressions of source face to target face. The generated face was composite to the target video's background. Thereafter authors utilized the mouth retrieval process where the best mouth match of target face from the offline training samples is used to preserve the originality of new generated mouth.

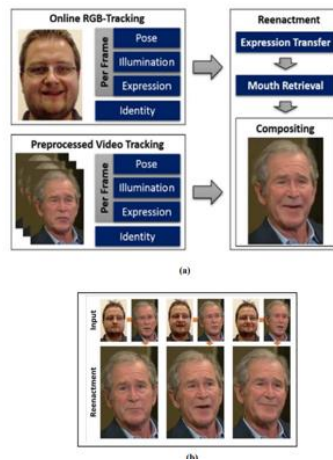

Figure 3.7: The Face2Face forgery generation method, adopted from [64] .

The method developed by Thies et al. in [64] is an efficient facial reenactment method. As this method was able to maintain the target mouth shape, which were simply copy-paste in other cases. The authors of FaceForensics++ dataset [35] have used Thies et al. method to generate Face2Face forged videos

VIDEO FORGERY DETECTION TECHNIQUES

The above discussed facial forgeries, namely Face2Face, DeepFakes and FaceSwap are popular and extensively used by researchers to design robust the facial forgery detection method. Rossler et al. [35] FaceForensics++ dataset comprises of these facial forged videos. These 25 forged videos appears to be genuine that humans are unable to detect them. To evaluate the robustness of Face2Face, DeepFakes and FaceSwap videos, the authors in [35] conducted a user study. In user study, the group of 143 persons were asked to tell whether the shown video is fake or real. And the results show that human average detection performance on FaceForensics++ dataset is almost 71% to 61% [35]. This shows an urgent requirement to develop detection methods for these videos to check their malicious usage.

The video forgery detection is a technique to authenticate the integrity of a given video. The video forgery detection techniques are broadly classified into following three groups:

Statistical based detection techniques

The statistical based detection techniques exploit the vital attributes of a given video to detect forgery. These statistical attributes are inconsistencies in video frames (in terms of brightness, shadows, etc.), Zernike moments, Fourier moments, DCT coefficients, color

space analysis, histogram comparison, etc. [62]. These detection techniques does not require any training on dataset to learn discriminant features.

Machine learning based detection techniques

The machine learning based detection techniques require a handcrafted feature set to learn the key points for detecting forged video. There are different machine learning based models available in literature such as Support Vector Machine (SVM), K-Nearest Neighbour (KNN), Logistic Regression (LR), Linear Discriminant Analysis (LDA) etc. [71], [72]. These detection methods require human intervention and their detection performance is also low in some cases [35].

Deep learning based detection techniques

Deep learning based algorithms are applied in various fields like medical science [7], market predictions, weather forecast, fashion industry [5], art and music [6], object detection and classification etc. The deep learning based approaches are very popular among the research communities as it is independent of hand crafted feature sets generation. Moreover, with recent developments, the training and testing of designed models on resource constraint platforms, becomes easy.

MOTIVATION BEHIND IMPLEMENTING DEEP LEARNING FRAMEWORKS

The above section discusses about the three different video forgery detection methods, i.e. statistical method, machine learning method and deep learning method. The statistical methods employ arithmetical, numerical or probabilistic operations to detect video forgery and the machine learning methods employ handcrafted feature sets based on intuitions, analysis and experimentation to authenticate the integrity of a video. Both of these methods are quite rigorous and require a lot of human intervention to select key distinguishing features. Deep learning method involves very minimal human intervention hence is very effective in increasing accuracy and reduction of error rate.

The video forgery detection methods depends on several intrinsic features of spatial and temporal domain of a video. In many cases, these features in combined manner are effecting the integrity of the video. Therefore manually designing the feature set for forgery detection would have been difficult and very complex task especially in the case of facially

manipulated videos. However with deep learning based methods, the video forgery detection becomes easy and automated. Moreover, it was observed in [35] the video forgery detection methods based on deep learning are performing better than methods based on machine learning. And researchers in [73] and [74] have proved that the convolutional neural networks (integral part of deep learning method) are the best in finding the granularity of the given input. the efficacy, accuracy, reduction in error rate, ease and automation of the deep learning based methods motivated us to design the four novel deep learning architectures aiming at detecting object based and facially manipulated videos. The key component of these four proposed architectures is convolutional neural network. Thus, it is discussed in detail in following section.

CONVOLUTIONAL NEURAL NETWORK (RNN)

A convolutional neural networks are inspired by the human visual cortex [75] and [76], which in an adaptive way learns to recognize an object on repeatedly observing it, irrespective of its position and orientation. The RNN learns features in a hierarchy i.e. from low level to high 27 level. A RNN includes convolutional layer, non-linear activation layer, pooling layer and fullyconnected layer. The first three layers are used to extract the features from the input. The extracted features are evolved during the training process. Finally these extracted features are utilized by fully-connected layer to map to the different classes. Stacking these three feature extracting layers many times with a fully-connected layer aggregates to form a deep neural network.

The convolutional layer at different levels in a network extract different features. The initial convolutional layers will extract low level features however the later layers extract high level features. Thus a network progressively learns the minute granularity of the input and is able to solve even the complex classification problems of image or video. These deep neural networks are first deployed by Krizhevsky et al. [73]. The deep neural network are difficult to train but definitely increases the classification or detection performance of the model. The figure 2.10 represents the basic architecture of RNN

CONCLUSION AND FUTURE WORK

Forgery detection for digital videos has become increasingly challenging in recent years with the advent of sophisticated yet easy to use digital video editing and forgery tools. The inability to easily detect malicious editing and forgery in digital videos has seeded distrust across social, legal, educational, and business platforms. There is a dire need for efficient and robust detectors for authenticating the integrity of digital videos.

This thesis work proposes four complimentary novel deep-learning based digital video forgery detection methods: temporal-RNN, spatial-RNN, fRNN and light-weight 3DRNN. The proposed temporal-RNN and spatial-RNN methods were found to be effective at providing comprehensive information related to forgeries made using object-based manipulation techniques.

The proposed fRNN and lightweight 3DRNN methods were found to be effective at detecting forgeries involving facial manipulation, as is common in DeepFake videos.

Temporal-RNN Method

The proposed temporal-RNN method works by extracting information related to motion residuals across frames from a video and processing that information through a temporal-RNN for classification in order to detect forged frames in the video.

In this method, motion residuals are computed by subtracting the current frame from the reference frame. The reference frame is computed using the collusion method instead of using the I-Frame of GOP structure of the video. This allows the detection method to be effective independent of GOP structure and therefore applicable on videos processed using advanced codecs such as MPEG-4, H.264, etc. where identifying the I-Frame is a difficult task in itself.

Activation map based visualized interpretation of results from this method confirmed strong activations for large blobs.

Multi-class (double-compressed, forged, pristine) and post processing attack evaluations as well as comparison against other steganalytic machine learning and statistical based methods further validated the efficacy of this proposed temporal-RNN.

Spatial-RNN Method

While the proposed temporal-RNN method is able to detect forged frames in a video, it is unable to localize the forgery detection to a region within the forged frames. In order to

localize the forged region within in a given forged frame, a spatial-RNN method was designed and implemented.

A novel approach of block level forgery localization was adopted in this method. The given forged frame was converted into forged motion residual frame and further divided into 128×128 sized non-overlapping blocks. These non-overlapping blocks were fed as an input to the proposed spatial-RNN.

A three convolutional layered architecture was used and hyper-parameters were selected experimentally. Due to unavailability of ground truth of forged region in a particular frame, a block level dataset was manually created and labeled for training and testing.

Activation maps based visualized interpretation showed blobs in the blocks containing the forgery, highlighting the primary feature of the spatial-RNN method.

The proposed temporal-RNN detects forged frames and proposed spatial-RNN marks forged 128 regions within a forged frame. Combined together, they make it possible to comprehensively detect object-based forgeries in a video.

fRNN Method

Videos featuring facial forgery generated using DeepFakes, FaceSwap and Face2Face have been spreading across social media in recent years and is seeding distrust in society. DeepFakes and FaceSwap are identity-based forged videos where the face of one person is swapped with another. Face2Face are expression-based forged videos where a person's face mimics facial expressions from another source.

This thesis proposes a novel detector for robust detection of such forgeries. This proposed detector analyses frequency features within a given video to detect facial manipulation and is therefore termed as frequency RNN(fRNN).

The proposed fRNN was further evaluated under multi-class classification scenarios. A multiclass classification test aimed at classifying a given video as DeepFake, Face2Face, FaceSwap, or pristine was also performed using videos of varying compression qualities. The results showed c0(uncompressed), c23 (lightly compressed), and c40 (highly compressed) average detection accuracy of 82.68%, 78.60%, and 62.78% respectively.

Besides binary and multi-class classification, the fRNN was also benchmarked on FaceForensics++ dataset. This benchmark platform allowed the proposed detector to be

compared with the other existing machine learning and deep learning based detectors. Results from this benchmark and other testing scenarios validated the effectiveness of proposed fRNN in detecting DeepFake, Face2Face, and FaceSwap.

Lightweight 3DRNN Method

The proposed lightweight 3DRNN is designed as a five convolutional layered architecture for detecting facial forgery in videos by exploiting the spatial and temporal features from the video. Spatial features are extracted from horizontal and vertical gradients of a video frame and temporal features are extracted from two consecutive video frames.

The proposed lightweight 3DRNN is fed with a $128 \times 128 \times 4$ sized matrix of video frames where first two frames are gradient frames of a current frame and remaining are two consecutive frames. The designed lightweight 3DRNN was found to be effective in detecting forgery in highly compressed (c40) videos where it attained binary classification accuracy of 90.99%, 83.48%, and 87.59% for DeepFakes, Face2Face, and FaceSwap respectively idated the robustness of the proposed method in detecting facially forged videos. The design of this proposed lightweight 3DRNN involves using the initial two convolutional layers for extracting the spatial features and the remaining three convolutional layers for extracting temporal features. This combination of convolutional layers results in 2.69 million trainable parameters, which is much smaller in comparison to the 44 million trainable parameters in the proposed fRNN.

ABSTRACT

The polluted water can cause various diseases to humans and animals, which in turn affects the life cycle of the ecosystem. If water pollution is detected at an early stage, suitable measures can be taken and critical situations can be avoided. To make a certain supply of pure water, the quality of the water should be examined in real-time. Smart solutions for monitoring of water pollution are getting more and more significant these days with innovation in sensors, communication, and Internet of Things (IoT) technology.

INTRODUCTION

Smart cities, as the name indicates, are the smart control of the cities by the use of various electronic methods, sensors, advanced communication techniques, etc. Here is where IoT (Internet of Things) plays a major role. IoT is used in creating smart cities to set up a firm connection between the sensors, devices, and networks that are used in setting up a smart city. Any IoT system contains Unique Identifiers (UIDs) that are used to transfer any information to any required network. The human efforts in controlling and monitoring the system are also reduced extensively by the use of

IoT in smart cities Keywords: Arduino, Cloud server, Conductivity, Controller, pH, Sensors, Turbidity, Water quality. The human efforts in controlling and monitoring the system are also reduced extensively by the use of IoT in smart cities Smart City is always considered as a standout amongst the most encouraging and noticeable Internet of Things (IoT) applications. Over the past few years, smart city idea plays a vital role in both academia and industry, with the improvement and arrangement of different middleware stages. IoT helps to build the world's largest urban communities at a sensational rate and there will be no need for human-to-human or human-to-computer interaction for monitoring and controlling the systems. Smart City is a platform created by the use of information and communication technologies to improve the quality of life.

LITERATURE SURVEY

System for Water Quality Monitoring and Distribution

D.Nirmala et al. [1] Water plays a vital role in the creation of human being and other natural phenomena. More than 80% of the resources is surrounded by water but in that only 20% is good for consumption others are fully polluted and contaminated. Now a day's water is more polluted, and even supplied in a very lesser level so to check and monitor the quality of the water we mainly using a number of sensors are used to monitor the water's quality and distribute it to the less fortunate. The quality of the water is affected by several parameters. Water is provided from difference resources like lake, pond, well, ground water, oceans etc.so these waters are not good for consumption Therefore, and our goal is to assess the water's quality while keeping an eye on the flow and level of the water. It is intended to use a variety of cutting-edge devices to check various water quality system parameters.

IOT Based Real Time River Water Quality Monitoring and Control System

P.M Dinesh et al.[2] Water quality monitoring systems currently in use are manual and involve tedious processes that are time intensive. This research suggests a

system with sensors for water quality monitoring. Access to real-time data may be obtained through remote monitoring and the Internet of Things. A wireless sensor network (WSN) contains a micro-controller for data processing, a mechanism for communicating between and inside nodes and many (IoT). Using Spark flow analysis with Spark MLlib, deep on it. The agent will receive a warning SMS automatically if the detected value exceeds the threshold. Our plan to develop a high- frequency, high-mobility, low-power water monitoring system makes it special. As a result, the Bangladeshi people will find our proposed approach highly useful in raising awareness of and putting an end to water pollution.

Real-Time Water Quality Monitoring Using Iot

A. Praveena et al.[3] There are numerous ways to consume water. People use municipal water, bore wells, and many other resources. But is it safe to drink straight from the ground or to filter it in any way? It might have dangerous substances in it, making it unfit for drinking. Drinking such water could have a number of negative health effects. Several things can contaminate water. Water pollution has an impact on both people and flora. We can determine its pollution level using IoT. We can keep an eye on the water's quality for drinking, agricultural, and domestic use. This water quality monitoring system uses various sensors and microcontrollers to find water quality, i.e., how the water's pH content and dissolved oxygen contents vary, and send the data to the users. The user can check the previous data and can know the pattern of the varied data, if any. This whole system fits in any water point. The values from the sensors are checked with the standard water qualities and the data is displayed in the web application from the cloud server.

EXISTING METHOD

The limitation of existing system has been overcome by the method called water monitoring and distribution. Especially people in rural areas and the under privileged people does not receive good quality of water and suffers from various waterborne diseases. This method helps in automatic filling of overhead tanks in

rural areas and the main advantages is like sensors provide accurate details of the quality of water. The water from the overhead tank is automatically opened through the solenoid valve for the user consumption based on time with the help of rtc,, as in villages the distribution of water will be in any time and the water is distributed only when the sensors value satisfies the condition. The IOT enabled solutions provides optimized smart water management system by including IOT sensors these sensors aid in real time monitoring of water consumption or leakage. The IOT sensors that were used here are Ph sensor, Turbidity sensor, Water flow sensor, Water level sensor for monitoring and management of water and the whole process is monitored in IoT to ascertain if supplies maintain the required degree of purity and to find out the extent of any variation that occurs and to find out organisms responsible for spreading of water borne diseases .Normally if the Ph of water is Lesser than 7 means it is referred as Acidic water and if it is greater than 7 means it is referred as alkaline and if it is accurately 7 means it is referred as neutral water and the turbidity must be less than 1 Nephelometric Turbidity Unit (NTU).The analysis of water is done in order to ascertain the quality of water whether it is subjected to physical and chemical test is done and the Physical test includes determining turbidity and chemical test includes alkanity and acidity of water. Now a days due to the work and daily touch schedule we cannot keep up time that too in the rural remote village they faces many basic problem like they will never know the timing when they will be supplying water to them so we are using real time clock where we are introducing and fixing a constant timing and the water quality is monitored by the mobile application. If they are supplying water twice a day then the fixed timing the water quality is checked and distributed based on time. Arduino uno is a microcontroller where all the sensors are interfaced and using IoT, the sensor's sensed will be displayed in lcd are noted. In the main tank the turbidity and Ph sensor are placed to monitor the water quality and in between main tank and the drinking water tank the water flow sensor is placed to verify the flow of the water then if it fails to satisfy

the level then second tank valve is opened and using solenoid valve water is let out for domestic use just by sensing and analysing the water quality level and distributing it to the remote village we can prevent the water scarcity as well as the water pollution so that they can use the right quality of water without getting any diseases. It was implemented it in our own houses, government schools, hostels etc.

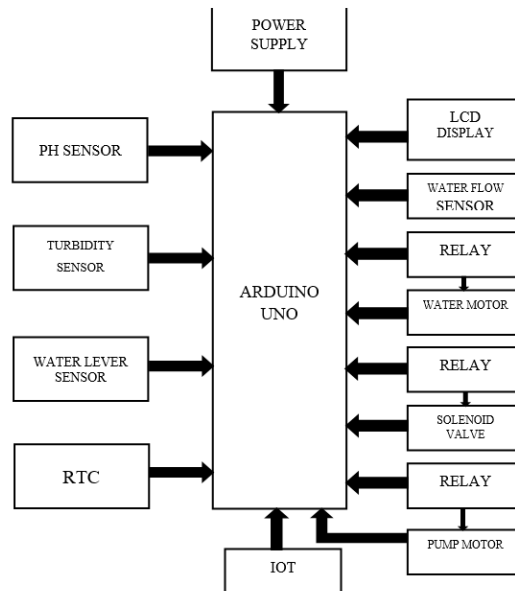

Fig. 1 water quality tracking and distribution system

The water quality monitoring and distribution system using IoT make it clear that every single individual in this world just consume right quality of water where as their will be no shortage of water in the future all the urban, rural emote places will get the water supply without any problem and using embedded c Arduino ide the codes are written to satisfy all the condition. water quality tracking and distribution system. The water quality is monitored automated using sensors. This method helps in automatic filling of overhead tanks in rural areas and the main advantages is like sensors provide accuratedetails of the quality of water. The water from the overhead tank is automatically opened through the solenoid valve for the user consumption. In this proposed method, Arduino microcontroller is used to interface with the sensors and to the uno communication devices. The Ph and Turbidity sensor is utilised to measure the water's PH level, which refers to acidity or alkalinity as well

as dust particle and turbidity, respectively. The water level sensor indicates the amount of flow sensor determines how much water is being utilised. The sensors' most recent value is displayed on the LCD.

Software

Fig. 2 Blynk IoT

Fig 2 displays sensor values in the mobile appBlynk. Arduino Integrated development environment and Embedded C are utilized for implementation. Node MCU is an open source IoT platform. Node MCU uses UART protocol for serial communication. By means of this protocol the sensor values are communicated with help of IOT. Thus, the water quality is monitored and displayed in Blynk IoT app where the sensed values are communicated with this app by means of node MCU. The Ph, turbidity, water level and the water flow will be displayed which is helpful for monitoring the water quality. The Flow chart explains the complete project like after giving power supply the water from the main tank is distributed to the village tank before supplying the water the Ph and Turbidity is sensed. If the water satisfies the condition it is send for drinking purpose or else it is sent for other purpose like agriculture and domestic use so use theflowchart above we can prove such conditions.The flow diagram depicts that the if the water level is less it is sensed by water level sensor and water is pumped from underground and the water quality is monitored using sensors and if the condition is satisfied the solenoid valve is opened on the basis of time. Water is the main factor so in the rural villages’ water supply and also water quality is very bad so we are taken a measure to sense the water

quality and distribution to the everyone in the particular fixed time. Thus, water is monitored and distributed. [4]

Fig. 3 Existing Method - Overall setup

The overall setup Figure 3 shows monitoring of turbidity, Ph and water flow and water level using IoT sensors have the distinct benefit that the system is affordable, can monitor water quality automatically, and doesn't need workers. Thus, with the help of proposed system water quality is analysed. In distribution systems, it is important to determine when and where water quality changes in the system. Thus, water is distributed on the basis of water quality and on time basis it is distributed to the user with the help of Rtc.

PROPOSED PLAN

In this project for a smart water quality monitoring system using IoT with TDS (Total Dissolved Solids) and temperature sensors. The implementation of a smart water quality monitoring system with TDS and temperature sensors involves deploying IoT-enabled sensors at key points within water sources. These sensors will continuously monitor two crucial parameters: TDS levels, indicating the number of dissolved substances in the water, and temperature, reflecting environmental conditions. The TDS sensors will measure the concentration of dissolved solids such as salts, minerals, and metals in the water, providing insights into its overall quality. Simultaneously, temperature sensors will monitor the water's temperature, which

can indicate changes in the environment and potential issues like pollution. Data collected by these sensors will be transmitted wirelessly to a central server or cloud-based platform in real-time. Here, advanced analytics and algorithms can process the information, detecting anomalies or deviations from normal levels. If TDS levels exceed predetermined thresholds or if there are unusual temperature fluctuations, the system can trigger alerts for immediate attention. Authorities and stakeholders will have access to a user-friendly interface, allowing them to monitor water quality remotely. Historical data will be stored for trend analysis, enabling better decision-making for water management and environmental protection measures. [5]

ESP32 Microcontroller

The ESP32 microcontroller operates on the principle of integrating multiple functionalities into a single chip, enabling versatile embedded system development. Its dual-core Xtensa LX6 processor provides high performance while managing power consumption efficiently. With built-in Wi-Fi and Bluetooth capabilities, the ESP32 can seamlessly connect to wireless networks and communicate with other devices. Its extensive array of peripheral interfaces allows for interaction with a wide range of sensors, actuators, and external devices. Employing a real-time operating

system (RTOS) like Free RTOS, the ESP32 supports multitasking and concurrent execution of tasks as shown in Fig 5. [6]

Fig. 5 ESP 32 Microcontroller

Analog TDS Sensor

An analog TDS (Total Dissolved Solids) sensor operates on the principle of measuring the conductivity of a solution to determine the concentration of dissolved solids within it. When immersed in a liquid, the sensor's electrodes come into contact with ions present in the solution. These ions facilitate the flow of electric current between the electrodes. The conductivity of the solution is directly proportional to the concentration of ions, which in turn correlates with the TDS level. The sensor typically consists of two electrodes, often made of materials like platinum or graphite, which are inert and conductive. These electrodes are placed at a fixed distance from each other. When a voltage is applied across the electrodes, ions in the solution facilitate the flow of current, and the sensor measures the resulting conductivity is shown in Fig 6.

Fig. 6 Analog TDS sensor

DS18B20 Temperature Sensor

The DS18B20 is a digital temperature sensor that operates based on the principles of semiconductor technology and digital communication protocols. The sensor employs a semiconductor element whose electrical properties vary with temperature changes. When the DS18B20 is connected to a microcontroller via a single data line using the 1-Wire communication protocol, it initiates temperature measurements upon command. This digital interface and unique addressing scheme make the DS18B20 versatile for a wide range of applications, including industrial automation, environmental monitoring, and consumer electronics, where precise temperature measurement and digital communication are essential.

Fig. 7 DS18B20 Temperature Sensor

Connectivity

The ESP32 Board to the Analog TDS Sensor and DS18B20 Temperature Sensor as shown in Fig 8. We are using a temperature sensor because the temperature parameter is required for the Electrical Conductivity EC Value adjustment. When the temperature rises and falls, the EC values change significantly. Connect the 3.3V and GND pins of the ESP32 to the VCC and GND pins of the temperature and TDS sensors, respectively. The output analogue pin of the TDS Sensor needs to be connected to the ESP32 A0 pin or the 34 pin. In similar fashion, connect the DS18B20's output to the ESP32's 35 Pin. It is crucial to connect the DS18B20 output pin and 3.3V VCC as a dependent power source and pull a 4.7K resistor. [7]

OUTPUT

Hardware connection

A water quality monitoring system using IoT hardware, we utilize an ESP32 microcontroller alongside a TDS (Total Dissolved Solids) sensor and a temperature sensor. Connecting these components requires careful wiring and configuration. Firstly, the ESP32 is powered either via

Fig. 11 Proposed Hardware Setup

USB or a battery source. The TDS sensor, typically featuring VCC, GND, and Signal pins, is connected to the ESP32, with VCC linked to a 3.3V output, GND to ground, and Signal to a 34 pin. Similarly, for the temperature sensor, like the DS18B20, VCC and GND pins connect to 3.3V and ground respectively, while the Data pin is attached to another 35 pin.

It is shown in Fig 11. Following hardware setup, firmware development proceeds, initializing signal pins and implementing code to retrieve data from the sensors.

Optionally, Wi-Fi connectivity can be integrated to transmit data to a cloud server for remote monitoring. Once firmware deployment and hardware connections are established, the system facilitates real-time monitoring of water quality parameters, including TDS levels and temperature, enabling timely analysis and intervention when required as in Fig 12 & Fig 13.

CONCLUSION

The implementation of an IoT-based water quality monitoring system presents a transformative solution to the challenges of ensuring clean and safe water. By leveraging the capabilities of IoT sensors and data analytics, this system provides real-time insights into various water parameters, including pH levels, turbidity, and more. The ability to remotely monitor and access this data offers unprecedented

convenience and efficiency for water management authorities and stakeholders. With early detection of contamination and proactive response mechanisms, such a system not only safeguards public health but also promotes sustainable water resource management. As we navigate the complexities of environmental conservation, IoT-based water quality monitoring emerges as a vital tool in our quest for a healthier and more resilient ecosystem.

ABSTRACT

The project presents an overview of a sophisticated agricultural technology designed to enhance crop cultivation and disease management within controlled greenhouse environments. This innovative system combines cutting-edge sensors, data analytics, and automation to optimize the growth of crops while minimizing the risks associated with diseases. By continuously monitoring environmental parameters such as temperature, humidity, light levels, and soil conditions, the system ensures that crops receive the ideal conditions for growth. Moreover, it employs advanced image recognition algorithms to detect early signs of plant diseases, allowing for timely intervention and treatment. Agricultural practices are undergoing transformational changes driven by advancements in technology. The integration of deep learning techniques, specifically convolutional neural networks (CNNs), empowers the system to go beyond environmental monitoring. By analyzing images of crops, the system can detect early signs of diseases, a crucial factor in disease management. The project implements monitoring crop soil level, weather condition, disease identification and final stage of the crop using IoT and Deep learning-based systems.

INTRODUCTION

In the conventional method of cultivation, Certain issues arise with the conventional way of cultivation, such as crop disease and weather conditions that change frequently and impact the crop. Therefore, agricultural practices need to be modified to provide the highest possible level of crop output. Greenhouse farming has become increasingly essential in modern agriculture due to its ability to provide controlled environments for crop cultivation. However, ensuring optimal growth conditions and early detection of diseases within these enclosed spaces can be challenging.

This system represents a significant step forward in addressing these challenges by harnessing the power of technology. It introduces the concept of integrating various sensors, data analytics, and automation to create an intelligent and proactive approach to greenhouse management. The introduction also hints at the broader implications of this technology, including increased agricultural productivity, resource efficiency, and the potential to mitigate the impact of climate change on crop production. In essence, it outlines the rationale and motivation behind the development of the Greenhouse-based Crop Growth & Disease Monitoring System, setting the groundwork for the subsequent discussion in the research or project.

A greenhouse is a well-designed farm building. This improves crop security, transplantation, harvest generation, and product seeding by creating a more controlled environment. In many tropical countries, greenhouse development is used for cost-effective farming, including the production of vegetables, organic products, and new flowers. Plant creation in a greenhouse is mostly dependent on its ability to comply with optimum atmospheric development conditions, which are to achieve high return at wonderful quality, little natural burden, and inexpensive cost. To achieve certain goals, it is necessary to optimally control parameters like as light, humidity, temperature, and soil moisture through the use of water generation, warming, ventilation, and lighting.

Through consistent monitoring and regulation of these environmental factors, important information regarding the distinct effects of each element on obtaining the highest degree of harvest can be obtained.

The current extraordinary challenges with greenhouse are in its control. As a result, temperature variations in greenhouses are dependent on external temperatures, moisture content, and solar radiation levels. inadequate natural product quality and set that is often purchased due to inadequate light intensity and high stickiness.

LITERATURE SURVEY

There has been a thorough examination of sensors, devices, and communication protocols related to Internet of Things applications in greenhouses. By identifying the IoT-enabled greenhouse sensors, applications, communication protocols, important obstacles, and research gaps, a systematic literature review (SLR) is carried out. However, assembling an SLR can be used to appropriately aggregate or evaluate results pertaining to a particular area. The systematic literature review (SLR) assesses all researchers who have begun working on a given issue. It requires a significant amount of time and work, but a consistent technique makes the SLR more thorough. A study of the relevant literature was done before the SLR began. In order to select pertinent research articles for this SLR, a search string comprising primary, secondary, and supplementary keywords was constructed.

To effectively implement the countrywide dynamic habitat monitoring and early forecasting program for pests and diseases, an automated system built on a web GIS platform was created. The theme maps for disease and pest forecasting have now been made available. The national pest of China is the oriental migrating locust (*Locusta migratoria manilensis* (Meyen)), and the national disease is wheat yellow rust (*Puccinia striiformis*). We projected the rust and locust-infested areas in China for 2019 using the created approach, and the R-square values were higher than 0.87. By increasing monitoring and forecasting accuracy, this system will not only increase

the effectiveness of managing and preventing pests and diseases but also contribute to a decrease in the use of chemical pesticides, ensuring food security and sustainable agriculture.

By using a PN model, we can create appropriate reference temperatures, keep an eye on the greenhouse's conditions, and oversee the entire system. Additionally, a controlled awning was added to lessen the impact of the sun's beams. The suggested system can operate independently in the following ways: it can detect the outside temperature, identify peak energy consumption periods, track the sun's angles, generate an appropriate temperature, transmit that temperature as a reference signal for temperature control, ensure that the ambient greenhouse temperature reaches that reference temperature, and, in the event that it has no more tasks to complete, switch to standby mode.

This work's primary innovation is the integration of several techniques to create a smart system. These techniques include temperature regulation through a closed loop system, awning control, and greenhouse monitoring and supervision via PN. The end result is a smart framework that lowers energy consumption and guarantees a suitable growing environment for greenhouse plants. This is thought to be highly advantageous as it lowers production costs and achieves energy savings while maintaining the right conditions for plant growth.

EXISTING SYSTEM

Raspberry Pi and an Arduino chip

In agriculture greenhouse environmental monitoring, a Raspberry Pi and an Arduino chip were paired for the first time; the Raspberry Pi acted as the data server and the Arduino chip as the mobile system's master chip. First, the Raspberry Pi was used to host the application layer server. Secondly, the Raspberry Pi and other components were integrated into the mobile system, reducing the physical distance between the data processing and acquisition ends by using serial communication. This was made possible by the Raspberry Pi's small size and reliable performance.

Self-water producing through an enhanced water desalination process

The greenhouses' capacity to generate their water loads locally is the foundation of the current strategy. With the goal of saving energy and water, this study attempts to provide an effective decision tool that can carry out particular monitoring and control functions to maximize greenhouse operation. To precisely regulate and control the interior microclimate and define the ideal growth conditions for the crops, a decision model is put into practice. In addition, a predictive algorithm is created to model how the greenhouses would function in real time under different circumstances, evaluate how the system would react to changes in storage dynamics and renewable energy sources, and manage the intricate indoor microclimate, energy, and water flows to maximize crop growth.

Petri Nets (PN) & Energy-Efficient (EE)

The greenhouse environment is monitored using a Petri Nets (PN) model, which also generates an appropriate reference temperature that is subsequently passed to a temperature regulation block. The second goal is to create a scalable, Energy-Efficient (EE) system design that can manage enormous volumes of big data from sensors in the Internet of Things (IoT). This data is collected using a dynamic graph data model, which can be used for future analysis and prediction of production, crop growth rate, energy consumption, and other related issues. The design uses model transformations and model-driven architecture to turn data into organized form, organizing several conceivable unstructured formats of raw data acquired from different kinds of IoT devices in a uniform and technology-independent approach.

PROPOSED METHOD

The aim of the project is to revolutionize and enhance the precision and efficiency of crop cultivation within controlled greenhouse environments. This project seeks to address several critical objectives:

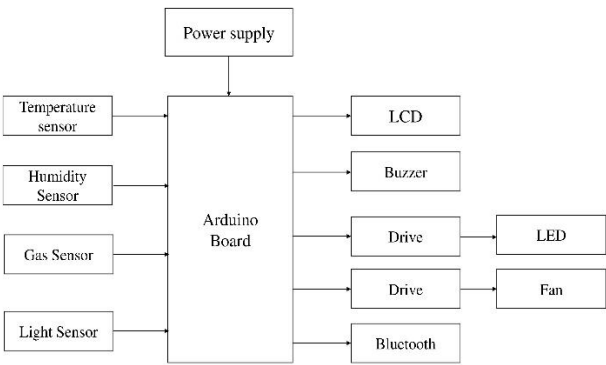

Optimizing Crop Growth: The primary goal is to create an ecosystem where crops receive the ideal environmental conditions for growth. By closely monitoring factors such as temperature, humidity, light, and soil quality, the system aims to provide crops with the optimal conditions required for robust and healthy growth throughout their life cycle.

Early Disease Detection: Another key objective is the early detection of plant diseases. Through advanced sensor technology and image recognition algorithms, the project aims to identify the initial signs of diseases in plants. This early detection allows for prompt intervention and treatment, minimizing crop damage and loss.

Resource Efficiency: The project strives to improve resource management within greenhouses. By precisely controlling environmental variables, it aims to reduce water, energy, and fertilizer consumption, thereby promoting sustainable and eco-friendly agricultural practices.

Increased Crop Yields: Ultimately, the project aims to boost crop yields within greenhouse settings. By ensuring optimal growth conditions and swift disease management, it seeks to increase the quantity and quality of harvested crops, contributing to food security and economic viability for greenhouse operators.

BLOCK DIAGRAM

WORKING PRINCIPLE

The system deploys an array of sensors throughout the greenhouse to continuously monitor critical environmental parameters. These sensors track factors such as temperature, humidity, light intensity, soil moisture, and nutrient levels. Real-time data from these sensors are collected and transmitted to a central control unit or cloud-based platform.

Next, the system's data analytics component comes into play. Sophisticated algorithms analyze the incoming data to assess whether the current conditions align with predefined optimal parameters for crop growth. If any deviations or anomalies are detected, the system triggers automated responses to rectify the situation. For instance, if the temperature falls below the desired range, the system can activate heaters to raise it to the optimal level.

In parallel, the system employs image recognition technology to monitor the health of the crops. High-resolution cameras capture images of the plants, and specialized algorithms analyze these images for signs of diseases or stress. When potential issues are identified, the system alerts greenhouse operators for further inspection and intervention.

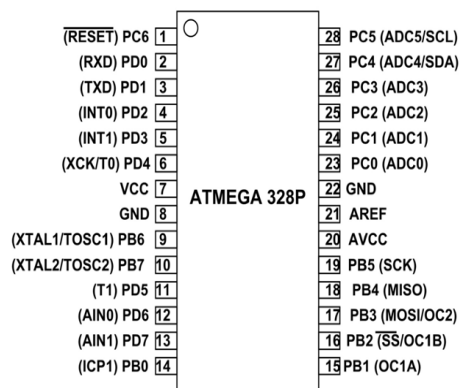

Throughout the process, the system maintains a historical database of environmental data and crop health information. This historical data is used not only for immediate decision-making but also for long-term analysis. It allows for the

identification of trends and patterns, enabling continuous refinement of the greenhouse environment and disease management strategies.

HARDWARE DESCRIPTION

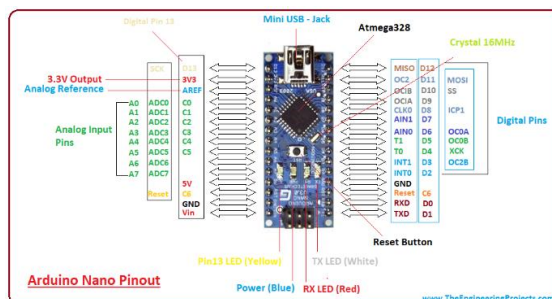

Microcontroller

An integrated circuit (IC) called a microcontroller is used to manage other electronic system components, often through memory, a microprocessor unit (MPU), and a few peripherals. These gadgets are designed with embedded applications in mind, which call for quick, responsive contact with digital, analog, or electromechanical components in addition to processing capabilities.

Arduino Nano

The Arduino Nano is an open-source breadboard-friendly microcontroller board based on the Microchip ATmega328P microcontroller (MCU) and developed by Arduino.cc and initially released in 2008. It offers the same connectivity and specs of the Arduino Uno board in a smaller form factor. Arduino Nano.

LM35 – Temperature Sensor

The electrical output of the integrated analog temperature sensor LM35 is proportional to degrees Celsius. For the LM35 Sensor to achieve normal accuracy, no external calibration or trimming is needed. The LM35's ability to interface with readout or control circuitry is facilitated by its low output impedance, linear output, and perfect intrinsic calibration. One of the most often observed parameters worldwide is temperature. Everyday household appliances including microwaves, refrigerators, air conditioners, and all engineering specialties use them. A temperature sensor essentially gauges the amount of heat or cold produced by the object it is attached to. After that, it outputs a proportionate amount of voltage, current, or resistance, which is measured or handled in accordance with our application.

Light Sensor

One kind of photo detector (also known as a photo sensor) that picks up light is a light sensor. To detect IL brightness, react to variations in the amount of light received, or convert light into energy, a variety of light sensors can be employed. Photodiodes, photo resistors, phototransistors, and photovoltaic light sensors are common types of light sensors. Applications for these components include proximity sensors, automated outdoor lighting, light detection in mobile devices, and renewable energy.

Light is converted into an electrical current by photodiodes. These are p-n junction semiconductors, which resemble typical diodes. Semiconducting materials of the p-type and n-type make up a p-n junction device. The “p” stands for “positive” due to

the material's excess of electron holes, and the "n" stands for "negative" due to an excess of electrons. This means that current can only flow in one direction through the boundary. In a photodiode, these electron hole pairs are formed when the energy from the incident light is absorbed by the device.

Air quality Sensor

Every air quality sensor we ship is capable of measuring the most prevalent air contaminants. Our environmental sensing platform may be expanded to incorporate even the most exotic pollutants for larger-scale projects. Data integrity is guaranteed by proprietary on-device data management.

The most recent connectivity standards for smart building and smart city projects are supported by our air quality sensors: Whether you're looking for fully autonomous sensors that use the cellular network for data transmission, or you want to set up long-range infrastructure networks with LoRa air quality sensors, you may use your current infrastructure with WiFi air quality sensors.

DHT11 - Humidity Sensor

The DHT11 Temperature & Humidity Sensor has a digital signal output that is calibrated in addition to a temperature and humidity sensor complex. It offers great dependability and outstanding long-term stability by utilizing temperature and

humidity sensing technologies along with an innovative digital signal collecting technique. This sensor links to a high-performance 8-bit microcontroller that offers great quality, quick response, anti-interference capability, and cost-effectiveness. It also features resistive-type humidity and NTC temperature measurement components.

Wireless Transceiver

A wireless transceiver is a vital component of wireless communication systems. The quality of the wireless transceiver determines the dependability and efficacy of information transfer in a wireless system.

A wireless transceiver is composed of two functional levels: the physical (PHY) layer and the media access control (MAC) layer. The PHY layer is composed of a baseband processor and an RF front end. The baseband processor modulates a bit stream into a constellation symbol stream for transmission. The receiver demodulates a stream of symbols to recover the transmitted signal

The RF front end of the wireless transceiver downconverts the received RF signal to baseband and adds an RF carrier to the baseband symbol stream for transmission. The MAC layer provides link traffic control for the wireless transmitter to access the wireless links, avoid collisions, and optimize data throughput.

LCD Display

LCD (Liquid Crystal Display) operates primarily through the usage of liquid crystals. Since LEDs are frequently used in computer monitors, instrument panels, televisions, cellphones, and other devices, there is a wide range of applications for both consumers and enterprises.

When compared to the technologies they superseded, such as gas-plasma and light-emitting diode (LED) displays, LCDs represented a significant advancement. Compared to cathode ray tube (CRT) technology, LCDs permitted screens to be far thinner. Compared to LED and gas-display screens, LCDs use a lot less electricity because their operating principle is to block light instead of emit it. The liquid crystals in an LCD use a backlight to create an image where an LED emits light.

Power Supply

LCDs were a major advancement over the technology they replaced, such as gas-plasma and light-emitting diode (LED) displays. LCDs allowed for much thinner screens than those made possible by cathode ray tube (CRT) technology. LCDs use a lot less electricity than gas-display displays and LED screens since its working concept is to block light rather than emit it. Where an LED emits light, the liquid crystals in the LCD use a backlight to create an image.

Above all, it is crucial to understand that an amplifier is nothing more than a modulator that regulates the energy transfer from the power source to the load. Even the most exquisitely built amplifier will be worthless if the power supply is subpar and cannot provide the energy needed to fulfill the amplifier's peak needs. A DC High Tension (HT) supply and one or more heater, or Low Tension (LT), supplies – which might be AC or DC – are required for valve amplifiers. Though it's not always the case, the power supply, which is usually integrated inside the power amplifier, serves as the source of power for both the pre-amp and power amplifier.

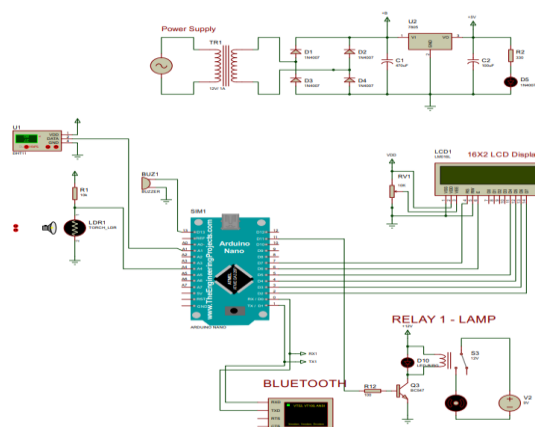

APPLICATIONS

The system helps optimize crop growth by monitoring and controlling environmental factors such as temperature, humidity, and light. This results in improved crop yields and quality.

It detects signs of diseases or stress in plants through image recognition technology and alerts farmers, enabling timely intervention and reducing crop losses.

Large-scale greenhouse operators can benefit from increased productivity and reduced operational costs, making their businesses more competitive and sustainable.

CIRCUIT DIAGRAM

RESULT

Greenhouse-based Crop Growth & Disease Monitoring System encompass higher yields, improved crop quality, resource efficiency, disease management, data-driven decision-making, sustainability, operational efficiency, climate adaptation, and ongoing agricultural innovation. These outcomes collectively contribute to the success and resilience of greenhouse farming in the face of evolving challenges in the agricultural industry.

Improved environmental monitoring and disease detection contribute to better crop quality. This outcome is particularly valuable for producing premium crops that meet stringent quality standards, commanding higher market prices. The system's data-driven approach minimizes resource wastage by precisely managing water, energy, and fertilizers. This efficiency not only reduces operational costs but also supports sustainable farming practices by minimizing environmental impact. The data generated by the system supports ongoing research and innovation in greenhouse farming, leading to the development of new techniques and technologies for improved crop cultivation.

CONCLUSION

The Greenhouse-based Crop Growth & Disease Monitoring System represents a groundbreaking and transformative approach to modern agriculture. It combines advanced sensor technology, data analytics, and automation to create a dynamic and responsive ecosystem within controlled greenhouse environments. Throughout our exploration of this innovative system, it has become evident that its potential benefits are extensive and far-reaching.

This technology offers the promise of increased crop yields, improved crop quality, and enhanced resource efficiency. By ensuring that crops receive the optimal environmental conditions for growth and promptly detecting signs of diseases or stress, it empowers greenhouse operators to achieve higher levels of productivity and profitability while minimizing environmental impact. The system's data-driven

approach not only supports informed decision-making but also fosters ongoing research and development in the field of greenhouse farming.

ABSTRACT

The constant progress in the technological world, worries about safety grow more and more pressing every day. Keys that provide protection are easily duplicated. This will prevent theft and criminal activity. This smart security system, thus, uses a buzzer, a camera module, and an Arduino microcontroller. In this paper we have proposed a model with major security techniques. The method provides security for the locker room door by face identification using Open CV is a type of biometric system to analyze the obtained information and identify the user uniquely by the trained images. In this proposed model the images of customers are trained. Arduino board which acts as a microcontroller unit. Using IOT, mail will be directed to the required person.

INTRODUCTION

A combination of lock and key is one method of securing an object. Modern locks and locking systems are much more sophisticated, and they frequently employ a dotted mechanism on the key to increase security. However, mechanism behind the lock and key is the same, which means that with enough work, the security system and the key can always be copied. Even though the locking system is protected, others can still easily see it. For the purpose of get around this, create a "secret

knocking pattern." Recognition plays a major role in this technology. The term "recognition" is used to describe the basic functions of biometric methods such as facial, fingerprint, and iris recognition; however, it does not always imply verification. either open-set or closed-set identification.

Verification is the process by which the biometric system compares a sample that has been supplied to one or more templates that were already enrolled in an effort to validate a person's claimed identification..

RELATED WORK

RFID based super secure door lock system is not needing to carry out the key. The electrically powered systems may not function properly if power gets failure. Even with the advent of sophisticated door locks and digital password lockers, it is now very easy for an unauthorized individual to crack the lock code. There are numerous electronic locks on the market right now that are based on IOT, RFID, biometrics, passwords, OTP, cryptography, and wireless technology. Every system has benefits and drawbacks, with some systems being able to prevail the shortcomings of others. The single factor authentication offered by the current technologies makes them less secure. So as to activate, verify, and validate the user and open the door in real time for safe access, a reliable door locking system with two-factor authentication and numerous encryptions employing RFID has been proposed.

Bio metric based authenticated system focuses on providing a safe, authentic and user-friendly mechanism for both the customer's of the bank holding a locker and the branch head's involvement in all operations pertaining to the safety lockers. The ultimate goal is to offer a comprehensive biometric-based authentication mechanism solution for the safety lockers. This mechanism rests on improving the current fact that all the lockers that operates currently operates only by using two different keys – one the branch head's key & other the user key. It is suggested to improve the present concept, which mostly depends on the user's key to operate the locker using biometric and secret code (password). User Interface Users' privacy may be restricted

by biometric gadgets such as facial recognition software. Users' privacy may be restricted by biometric gadgets such as facial recognition software.

IOT based smart locker security system is for highly secured reliable smart locker system. The system will take into account the security of the bank locker rooms in order to efficiently detect and control unwanted access. It will persuade bank customers to utilize the system, protecting their valuables from theft and other harm. When extreme security is required, this approach is employed. Future improvements to this job could include the addition of new features like face recognition. As a result, it increased bank locker dependability and reduced the likelihood of illegal access. The improvement might be used one more time to locate the unauthorized entry.

A biometric and GSM-enabled advanced security system is an effective means of bank evacuation. reduced waiting time and faster reaction times. completely automated system. robust system with little power consumption. To open the locker, the user and bank workers must both be present with the keys. The system is insecure since there is a chance that the key will be lost.

The primary objective of this project is to build an advanced security system for bank lockers that makes use of GSM and biometric technologies. This system will offer a safe, reliable, and easy-to-use method for opening safety lockers. This can be set up in homes, offices, and banks. The safest location to keep valuables is a bank locker. However, modern bank security systems employ the mechanical key approach, in which one of the two keys is held by a user and the other by an authorized bank official. To improve on this, we suggested a sophisticated GSM and biometric security solution for bank lockers. Initial enrollment in this system requires a finger print, username, password, and mobile number. The user must input their password and username while logging in.

PROPOSED SYSTEM

The Arduino Uno, camera, and buzzer are the components of the security pattern, which is used for security purposes and is only visible to the owner. The person face is also detected through camera if knocking pattern and face discovery matches the door will unlock and if any misread pattern or unknown person tries to enter a mail will be showed to the owner and buzzer alert provided.

Infrared detectors are mostly used to create a three-dimensional pattern of an individual's cranial physiognomy. This illustrates the process of obtaining the image using infrared technology.

HARDWARE MODULES

Arduino Uno is a micro-controller is a small computer on a single integrated circuit containing a processor core, memory, and programmable input/ output peripherals. The important part for us is that a micro-controller contains the processor (which all computers have) and memory, and some input/output pins that you can control. (often called GPIO - General Purpose Input Output Pins).

A relay acts as a switch that runs on electricity. A magnetic field produced by current passing through the relay's coil draws a lever, changing the switch contacts. Relays feature two switch settings because the coil current can be either on or off and they are double throw (changeover) switches.

Stepper motor is a device which translates an electrical signal to a positional change of a shaft. They are driven by pulses. Stepper motor depend upon reluctance torque only. The stepper motor will move a load a discrete amount for each pulse and then stop and do nothing until another pulse is applied.

Some security alarm systems include passive infrared sensors, or PIRs, which are electronic devices that detect motion from an infrared emitting source, usually a human body. A signalling device is a buzzer or beeper. Typically, these devices are based on an electromechanical system that functions similarly to an electric bell but without the metal gong that produces the ringing noise.

SOFTWARE MODULES

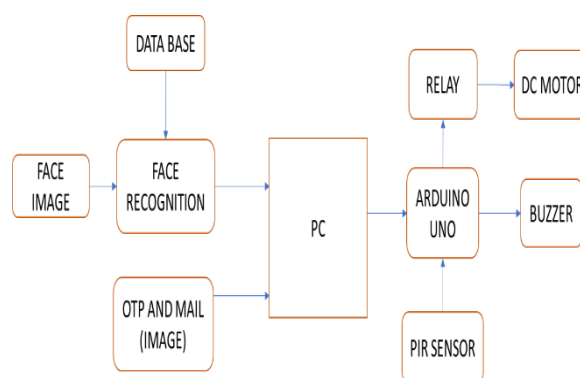

The Arduino Integrated Development Environment - or The Arduino Software (IDE) includes a text editor to write a code, a message section, a text console, a toolbar with buttons for frequently used activities, and an array of menus.

Embedded C: Arduino boards are programmed in C. Embedded C is a popular system programming language that has minimal execution time on hardware in comparison to other high-level programming languages.

Python: Python is a widely used general-purpose, high level programming language. It was designed with an emphasis on code readability, and its syntax allows programmers to express their concepts in fewer lines of code.

An open-source software library for computer vision and machine learning is called OpenCV (Open-Source Computer Vision Library). With its standard architecture used for computer vision applications, OpenCV aims to expedite the consolidation of machine perception in consumer goods. The BSD license for OpenCV makes it simple for companies to use and alter the source.

Face recognizing bank locker security system

To do facial recognition, an owner's photo is captured using a camera. Locker opens when face matches matching one.

If not, an email will be sent to the locker's owner, who will be notified if someone else tries to open it. Based on the program loaded on the Arduino UNO the output will be executed by the buzzer and motor.

RESULTS & DISCUSSION

Prototype Model

Face recognizing bank locker security system recognize the face of the owner and if suppose unauthorized person access the locker the notification will be send through Buzzer alarm and the motor.

CONCLUSION

Among the supporting services provide to its customers is Bank Locker facility, which are safe deposit lockers that allow the bank's customers to store their important and valuable items. Many individuals prefer to store their valuables such as jewelry, important documents, etc. Implicit guarantee of your money inside the bank being safe has usually been the reality of concernment. This project plays a first-

rate function in maintaining the safety and security of the respective valuables, financial institution being the utmost priority.

The proposed device is reliable, inexpensive with suitable layout. This undertaking Bank Locker Security System with high protection and Live Image authentication ensures to promote encouraging and improvised results, improving the safety and secureness over the presently present technologies.

FUTURE SCOPE

Nothing is perfect in this world but there are always chances of betterment and evolution of any system or product. Hence in our project “High Protection Bank Locker Security System Using Live Image And Authentication” we are looking towards the following future additions and amendments for making this system more efficient, reliable and building solid relationship between customers and their bank or users and locker service providers organizations.

Face recognition systems addition.

Voice recognition systems addition.

GSM module for OTPS and two step verification through mobile of user.

Data encryption.

IRIS scanners can also be added.

Multi-biometrics can be used for ultimate authentication.

ABSTRACT

As the world move forward in various fields like research and development, conservation of energy is a major issue to be resolved. The generation of electricity is a critical aspect of modern society. Traditional methods of generating electricity often rely on the burning of fossil fuels or nuclear reactions, both of which can have negative environmental impacts. Furthermore, these methods of power generation are limited by the availability of resources and can be costly. Hence, there is a need to develop a solution that overcomes these limitations. One such renewable source of energy is kinetic energy. To meet load demand, renewable energy can provide the necessary amount of clean energy for atmosphere stabilization and scale down the consumption of fossil fuel. This paper proposes a novel method by using a spring to capture and convert mechanical energy into electrical energy from human movements like walking and subsequently charging various mobile devices and powering electrical appliances, offering a sustainable and eco-friendly energy solution.

INTRODUCTION

Generally, the generation of electricity is a critical aspect of modern society. Traditional methods of generating electricity often rely on the burning of fossil fuels or nuclear reactions, both of which can have negative environmental impacts. Burning fossil fuels releases greenhouse gases (such as carbon dioxide) and other pollutants into the atmosphere, contributing to climate change and air pollution. This can lead to various environmental problems such as global warming, acid rain, and health issues. Furthermore, these methods of power generation are limited by the availability of resources and can be costly.

The worldwide search for sustainable energy solutions is more important than ever in light of growing environmental concerns and the necessity to lessen the effects of climate change. The idea of renewable energy, a revolutionary method of producing electricity by utilizing natural resources to minimize environmental damage, is at the forefront of this movement. Renewable energy comes from sources including sunlight, wind, water, and geothermal heat, in contrast to traditional energy sources that severely increase greenhouse gas emissions and deplete finite fossil resources. There has been increasing interest in the development of renewable and sustainable sources of energy to offset the use of traditional power generation methods.

In a time of technology advancement and digital connectedness, mobile device ubiquity has come to represent the way we live today. These portable companions, which range from smartphones to tablets and wearable technology, have easily incorporated themselves into every aspect of our everyday lives. However, in the midst of this digital revolution, there is still a critical need for dependable and environmentally friendly mobile charging solutions. The demand for eco-friendly and economical solutions to power our gadgets is rising along with the popularity of mobile technology. This introduction lays the groundwork for a discussion of how the field of mobile charging is changing, looking at energy requirements, technology

developments, and – above all – the growing trend toward environmentally friendly solutions that are in line with our shared duty to protect the environment. Finding a more sustainable and environmentally friendly way to charge our phones has become essential as we traverse this intersection of convenience and environmental awareness.

The idea of eco-friendly technology emerged in the period of rapid technological growth as a result of the necessity to balance innovation with environmental care. In light of the profound effects of climate change and resource depletion, there is a pressing need to adopt sustainable practices in all facets of our existence. Eco-friendly technology is a paradigm change, moving away from traditional methods that put human convenience ahead of environmental sustainability. This introduction lays the groundwork for an investigation into the field of environmentally friendly technology, exploring the creative approaches, methods, and ideologies that seek to reduce the environmental impact of our digital age. The conversation around environmentally friendly technology, which includes anything from recycled materials to energy-efficient designs, speaks to our shared obligation to pave a more morally and sustainably responsible pathway for future advancement.

GENERATION OF ELECTRICITY

This paper proposes a novel method by using a spring technology to capture and convert mechanical energy into electrical energy. fig 1 describes the flow chart of the proposed system.

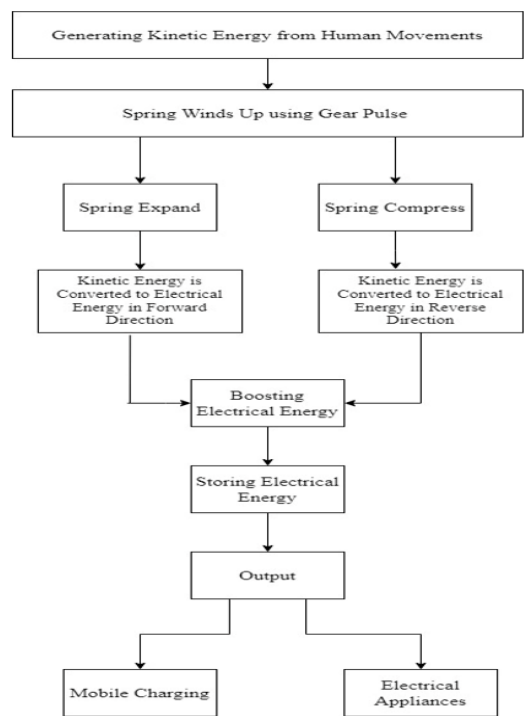

Fig. 1. Flow Chart of the Proposed System

As an initial step turnstile involves harnessing kinetic energy from human movements, such as walking or running. As individuals engage in these physical activities, their movements generate kinetic energy, which serves as the primary input for the energy generation system. This initial stage highlights the innovative utilization of natural human movements as a renewable resource for energy production. fig 2 depicts the appearance of the turnstile.

Fig. 2 Depicts the appearance of the turnstile

This approach integrates energy generation into daily routines, emphasizing the practicality and convenience of the system. Overall, the recognition of the abundant energy potential in human movements sets the stage for a sustainable and efficient energy generation process.

Table 1 Illustrate the Specifications of Turnstile

Parameters of Turnstile	Values	Units

Radius	7.5	cm
Diameter	15	cm
Circumference	47.12	cm

As a next step the turnstile is attached with Gear strip as shown in fig 3 involves the conversion of the kinetic energy generated from human movements into mechanical energy through a gear mechanism.

Fig. 3. Depicts the Appearance of Gear Strip and Dual-Sided Rack Gear Strip

Table 2 Illustrate the Specifications of Gear Strip Attached with Turnstile

As the kinetic energy is transferred to the system, the gear mechanism efficiently winds up a spring shown in fig 4, storing the mechanical energy for further conversion. This step demonstrates the strategic use of mechanical components to capture and store the initial kinetic energy input, facilitating its conversion into electrical energy in subsequent stages. The spring, which has been wound up using the kinetic energy generated from human movements, is used to rotate a DC dynamo in the forward direction. As the spring expands, it releases the stored mechanical energy, which is then transferred to the DC dynamo through a gear system. The

rotational motion of the DC dynamo is then converted into electrical energy, employing principles of electromagnetic induction.

Fig. 4. Spring and DC Dynamo

The spring, which has previously expanded to release its stored kinetic energy, now undergoes a reverse process. The spring is now compressed back, through a mechanism similar to the one used for winding it up initially. As the spring compresses, it exerts force in the opposite direction, which is harnessed to rotate the DC dynamo in the backward direction. This reverse rotation converts the mechanical energy from the compressed spring into electrical energy using the same electromagnetic induction principles as in expanding spring. As the DC motor spins in the opposite direction, it generates an electrical current, resulting in the conversion of kinetic energy into electric energy.

Table 4 Illustrate the Specifications of Gear Strip Attached with DC Motor

Parameters of Gear Strip	Values	Unit
Number of Teeth	25	-
Material	Plastic	-
Bore Diameter	6	mm

Pitch Diameter	25	mm

Table 5 Illustrate the Specifications of Spring

Parameters of Spring	Values	Unit
Material	Steel	-
Wire Diameter	1.5	mm
Outer Diameter	15	mm
Inner Diameter	12	mm
Total Number of Coils	47	Turns
Free Length	50	mm
Initial Tension	10	N
Spring Constant	200	N/m

By using the above values as shown in table 5 we can calculate the Extended Spring Length;

Extended Length = Free Length + (Number of Coils * Wire Diameter) - (Initial Tension / Spring Constant)

Extended Length = 50 mm + (47 coils * 1.5 mm) - (10 N / 200 N/m) = 50 mm + 70.5 mm - 0.05 m \approx 120.45 mm

By using the above values as shown in table 5 we can calculate the Compressed Spring Length;

Compressed Length = Free Length - (Number of Coils * Wire Diameter) + (Initial Tension / Spring Constant)

Compressed Length = 50 mm - (47 coils * 1.5 mm) + (10 N / 200 N/m) = 50 mm - 70.5 mm + 0.05 m \approx -20.45 mm

The electrical energy generated from both the forward and backward rotations of the DC Dynamo undergo an enhancement process. This enhancement is facilitated by employing a DC-to-DC boost converter as shown in fig 5, a device designed to elevate the voltage level of the electrical energy. By increasing the voltage, the boost converter ensures that the electrical energy is optimized for storage and usage, making it more efficient and versatile. This boosted energy is vital for maintaining a consistent and reliable power supply, especially when considering fluctuations in energy output from the kinetic sources. The boost converter plays a pivotal role in maximizing the effectiveness of the entire energy conversion system, ultimately contributing to the overall efficiency and performance of the process.

Fig. 5. Depicts the Appearance of DC-DC Boost Converter

The electrical energy from the DC-to-DC Boost Converter is efficiently stored in a lead acid battery as shown in fig 6 . The charge that is produced by the human movement is stored in the battery. The voltage is stored in D.C form.

The energy storage process ensures that the electricity produced from the kinetic energy of human movement is not wasted and can be accessed when needed. The battery serves as a reservoir for storing the converted electrical energy, allowing for flexibility in its utilization.

Fig. 6. Depicts Lead Acid Battery

The stored electric energy from the battery is utilized for mobile charging via a USB port. USB ports typically provide a standard voltage of around 5 volts, making them compatible with a wide range of mobile devices such as smartphones, tablets, and other gadgets that operate within this voltage range. By connecting the battery to the USB port, the stored energy is made available to charge these devices efficiently. This approach ensures compatibility and effectiveness in charging various mobile devices, making it a convenient and practical solution for powering electronics.

The stored electric energy from the battery is also utilized to power electrical appliances via a socket. This stage involves connecting the battery to a socket, which serves as an interface for powering a variety of electrical devices and appliances. With the stored energy readily available, users can plug in appliances such as lamps, fans, or small electronic devices, enabling them to function without requiring a direct connection to the main power grid. This application provides flexibility and convenience, particularly in situations where access to conventional power sources may be limited or unavailable. By tapping into the stored electric energy, individuals can continue to use essential appliances and devices, enhancing comfort and productivity even in off-grid or remote locations.

RESULT

Fig. 8. Illustrates the Output Voltage of DC Dynamo in Forward Direction

The line graph illustrates in the fig 8 is the output voltage from the DC Dynamo in the forward direction, corresponding to different numbers of people crossing the turnstile. The x-axis represents the number of people (ranging from 1 to 10), while the y-axis represents the voltage output (ranging from 0.5 to 3.5 volts). Two distinct line graphs are plotted on the same graph to depict the voltage output for both slow and fast movements. The slow movement line, depicted in red, starts from 1 person with a voltage of 0.7 volts and gradually increases to 2.52 volts at 10 people. Conversely, the fast movement line, represented in blue, starts from 1 person with a minimum voltage of 1.54 volts and reaches 3.45 volts at 10 people. This visualization allows for a clear comparison between the voltage output for slow and fast movements as the number of people crossing the turbine increases, highlighting the variability in voltage generation based on the speed of movement.

Fig. 9. Illustrates the Output Voltage of DC Dynamo in Reverse Direction

The line graph illustrates in the fig 9 is the output voltage from the DC Dynamo in the reverse direction, corresponding to different numbers of people crossing the turnstile. The x-axis represents the number of people (ranging from 1 to 10), while the y-axis represents the voltage output, with values ranging from a minimum of 2.54 volts to a maximum of 3.3 volts. Two distinct line graphs are plotted on the same graph to depict the voltage output for both slow and fast movements. The first line graph, depicted in red, represents the voltage output for slow movement. The voltage output fluctuates between up and down movements within the range of 2.54 to 3.3 volts. The second line graph, shown in blue, represents the voltage output for fast movement. Similarly, the voltage output varies in a zigzag pattern between 2.54 and 3.3 volts. This visual representation captures the dynamic fluctuations in voltage output from the DC Dynamo in the reverse direction for both slow and fast movements, providing insights into the variability of the voltage generation process.

Fig. 10. Illustrates the Output Voltage of DC-DC Boost Converter

The bar graph illustrates in the fig 10 is the output voltage from the DC-DC boost converter, categorized by different levels of movement speed represented by slow and fast movements. The x-axis of the graph represents the types of movement (slow and fast), while the y-axis represents the voltage output (ranging from 10.5 to 12.4 volts). Two distinct bar graphs are presented on the same graph, differentiated by colour; The first bar graph, depicted in red, represents the voltage output for slow movement. It starts at a minimum voltage of 10.5 volts and reaches a maximum of 11.65 volts. The second bar graph, depicted in blue, represents the voltage output for fast movement. It starts at a minimum voltage of 11.5 volts and reaches a maximum of 12.4 volts. This visual representation allows for a comparison between the voltage output for slow and fast movements from the DC to DC boost converter, showcasing the differences in voltage generation based on movement speed

CONCLUSION

This paper demonstrates the harnessing of kinetic energy from human movement to generate electrical energy using a DC Dynamo and a DC-to-DC boost converter. Through meticulous experimentation and analysis, we observed the generation of electrical energy both in the forward and reverse directions, with varying voltage outputs corresponding to different levels of movement.

The paper showcased the versatility and sustainability of utilizing human movements as a renewable energy source, with potential applications in various settings such as urban environments, workplaces, and public spaces. By converting kinetic energy into electrical energy, we contribute to sustainable energy practices while reducing reliance on non-renewable sources. Furthermore, the paper utilized graphical representations, such as line graphs and bar graphs, to visually depict the voltage output from the DC Dynamo and DC to DC boost converter. These visual aids provided clear insights into the relationship between movement speed and energy generation. In summary, our paper provides valuable insights into the potential of kinetic energy harvesting for practical energy generation, and

emphasizes the importance of sustainable energy solutions in addressing current and future energy challenges.

ABSTRACT

this work proposes a new bidirectional latch-based shift register as an alternative to conventional D flip-flops. The development is executed using Cadence Virtuoso EDA Tool using 90nm technology of an 8-bit shift register the maximum speed attained is approximately 200MHz. The power consumption and power dissipation are low compared to the conventional cells proposed earlier. Temporary storage helps the data to be stored unchanged in the last bit opposite to the input side. Reducing individual clocks to the registers, 2 to 1 multiplexer, and the master-slave flip flops gives the efficiency to area. The power consumption for 2 MHz is 16.48uW. The energy is calculated with the product of the dynamic power and clock speed, the result obtained is 82.4fJ which is very minimum for the proposed 8-bit bidirectional shift register using bidirectional pulsed latches.

INTRODUCTION

The demands of modern electronic devices emphasize high speed, low power, and area efficiency. Shift registers are pivotal in data storage and movement within electronic devices. This work focuses on bidirectional latches and pulsed techniques

to enhance efficiency, particularly low power consumption and reduced area utilization. The use of bidirectional latches and pulsed techniques represents an innovative approach to overcome the limitations of traditional designs. Incorporating these advancements in shift registers aligns with the continuous pursuit of optimizing electronic device performance. Using a single clock pulse design aims to reduce time delay, making the shift register suitable for high-speed electronic devices where minimizing delays is crucial. This work, ensuring compatibility with the requirements of contemporary electronic devices focused on high speed, low power consumption, and efficient use of space. This design in synchronous serial communication interfaces involves integrating the innovative shift register design into the communication system.

INVERTER

A basic CMOS inverter is a fundamental digital electronic circuit using Metal-Oxide-Semiconductor (CMOS) transistors, Which Consist of two transistors connected in series – one NMOS and one PMOS[1]. The gate Terminals of these transistors serve as the input to the inverter. The Design is being Implemented Using 90nm technology. Fig.1 shows the circuit diagram of the MOS inverter.

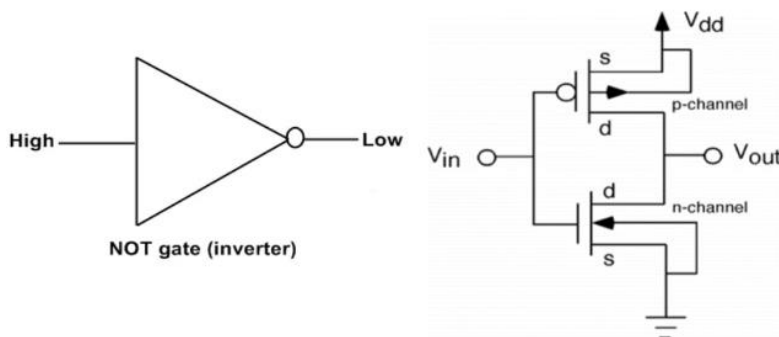

Fig 1. A fundamental CMOS inverter circuit

The CMOS inverter designed uses the PMOS and NMOS of the same W/L ratio (i.e. $W = 120\text{n}$; $L = 120\text{n}$). The inverter has the same W/L ratio, as the storing element is designed only for 1 bit and low power consumption.

PROPOSED METHODOLOGY

BIDIRECTIONAL PULSED LATCH

Fig 2. 1 bit memory cell

A memory cell is the basic unit of storage capable of holding binary information (0 or 1). It is a building block of memory systems and is essential for storing and retrieving data in digital circuits. In this method, memory cells are likely used to store and manipulate data in the bidirectional shift register. Basic Block diagram of 1-bit memory cell is shown in Fig. 2. Proposed Architecture of the N bit Shift Register is shown in Fig. 3

Fig. 3. Proposed Architecture of N bit Shift Register

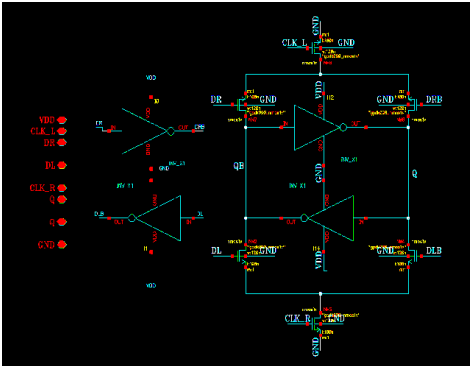

Fig. 4 BDPL Schematic

Bidirectional Pulsed Latch is capable of holding data on either side and designing a shift register allowing bidirectional data shifting using these latches, both left and right. Bidirectional Pulsed Latch (BDPL) as a groundbreaking solution for enhancing both efficiency and performance in electronic devices. By eliminating the need for a Master-Slave flip-flop and a 2-to-1 multiplexer, the BDPL not only reduces area requirements but also significantly cuts down on power consumption. The architecture of the BDPL is ingeniously designed, with left latch inputs (DL and DLB) connected to left latch outputs, and right latch inputs (DR and DR_B) linked to right latch outputs (Outputs -> Q and QB). This unique configuration enables seamless bidirectional data shifting, with latch data updating either left or right in response to a high pulse in CLK_R (Right Clock) or CLK_L (Left Clock). This approach ensures efficient storage and retrieval of data based on the specified clock signal, thereby optimizing overall performance. With its ability to store data based on CLK_R or CLK_L. The Bidirectional Pulsed Latch Schematic is shown in Fig. 4. The Proposed bidirectional shift register relies on bidirectional pulsed latches, combining a latch with a pulsed clock signal. Upon activation of the high pulsed clock signal for right or left shifting, the latch data updates accordingly, facilitating seamless data movement.

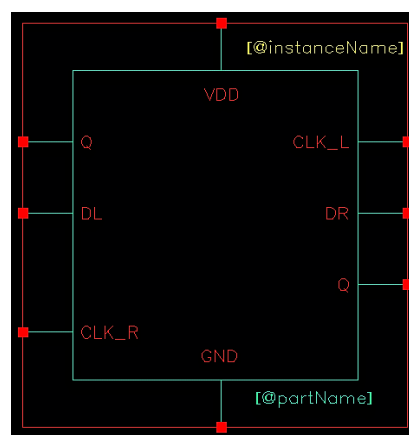

Fig .5 BDPL Symbol

The input data are given through the nodes of DR (Data Right) and DL (Data Left) (For ease of understanding and working, the nodes DL_B and DR_B (inputs) and QB

(output) are ignored). When the CLK_R (Right Clock) is triggered the output Q changes the state and stays constant until the CLK_L (Left Clock) is triggered. Fig. 5 Shows the BDPL Symbol.

Fig. 6 BDPL Waveform

BDSR (Bidirectional Shift register) uses sub-shift registers and additional temporary latches to reduce the number of pulsed clock signals. Temporary BDPL is added for storing input signals in the BDSR. For N bits of shift, registers require N+1 BDPL to shift data to the right or left using 5 pulsed clock signals for right or left shifting respectively. A 4-bit shift register and an 8-bit shift register have been developed by this proposed methodology. It contains the bit register, a storage cell, and a temporary storage cell, an input cell that receives input from the right or left. BDPL Waveform is shown in Fig. 6.

RESULTS AND DISCUSSION

A Cadence Virtuoso Schematic was created for a Bidirectional shift registers, which incorporated a bidirectional latch, bidirectional shift register, 4-bit Bidirectional shift register, 8-bit Bidirectional shift register. BDSR (Bidirectional Shift register) uses sub shift-registers and additional temporary latches to reduce the number of the pulsed clock signals.

ABSTRACT

In this research, we propose a novel approach for estimating fog density and performing image defogging by leveraging surrogate modeling techniques applied to the optical path. Atmospheric fog presents a significant challenge in various imaging applications, degrading image quality and reducing visibility. Our method focuses on accurately estimating fog density along the optical path, which is crucial for effective defogging. By utilizing surrogate modeling, we construct a predictive model of fog density based on input image characteristics and environmental factors. This model enables real-time estimation of fog density without relying on complex physical simulations, leading to efficient image defogging algorithms. We validate our approach through extensive experiments on diverse datasets, demonstrating its effectiveness in improving image clarity and restoring visibility in foggy conditions. Our proposed method offers a promising solution for enhancing imaging systems operating in challenging atmospheric environments.

INTRODUCTION

Video output which is difficult to process at a time and produce fog free output to the drivers. Hence, we are proposing a system that processes a video in frame-by-frame method i.e., image by image processing of a video. Our system is also capable

of evaluating the amount of fog density present in the outer atmosphere. Based on the density of fog presence in the atmosphere, the fog is removed in the image using fog aware density evaluator. This system can be used in both day and night time. The visibility alteration during night time causes several accidents. Our system is also capable of adjusting light intensity of the opposite vehicles can be removed at the processing phase of the image. The calculation of vehicle distance for impact is also estimated by this system which avoids collision. Fog mainly causes problems in vision applications such as video surveillance, remote sensing, defect recognition in the objects and navigation. Presence of outer atmospheric components such as aerosol and water droplets affect the visibility of the image due to defects such as absorption or scattering. Both absorption and scattering causes decrease in visibility if any of the factors is present in excess. This absorption and scattering are high only when the amount of fog present in the outer atmosphere is also high. This makes a tough situation of non-availability of road markings or objects. Thus, it is necessary to estimate scattering co-efficient.

LITERATURE REVIEW

The RGB color space in the image is converted into YCB Cr color space. Using Gabor filter and back scattered veil detection the density of fog in the image is estimated. This is used to analyze whether or not fog is present in the image and density of fog is estimated based on the intensity of light. [2] We use this method to calculate the threshold that is used to determine whether the fog present or not. Fog doesn't only cause changes in the quality of the image but it also causes changes in some image parameters such as contrast, color and luminescence due to the presence of fog in the outdoor image. We are introducing a reference free fog density prediction model which produces a fog free output image. Based on the depth of the pixel in the image and analyzing abrupt change in the pixel length are some basic steps in processing of the foggy image.

[3]. The estimation of visibility distance is calculated from the camera projection equation and blurring occur in the image due to the presence of fog. Thus, an automatic vision diagnostics system for ADAS is developed. Using this system, for fog detected image the cross verification is done using computer vision technique of evaluating an image. The suitable segmentation and ROI models are applied in the foggy image to obtain fog free output image. The algorithm used here is used to know the edge density and visibility distance so that the foggy region can be idealized and removed. The visibility is estimated by measuring the contrast attenuation of the markings in the road. In advanced to that using geographical information the automatic method for fog detection and estimation of visibility distance.

[4]. In anisotropic diffusion model RGB color model-based processing method that on Koschmieder's law as a fog removal algorithm. both smoothing and sharpening is done in intra-region as well as in the edges. Post processing is done and fog free output image is obtained. If the density of fog is high the complexity of the system is also high. [5]. Using adaptive wiener filter the amount of fog present in the image and distance of the object is calculated. The noise variation in the image is evaluated and removed. The outer atmospheric factors such as reflection, scattering and other contrast variation in the image are corrected. Finally, the fog free output image is obtained.

[6]. In color attenuation prior, fog is calculated using mathematical function of realization. The depth of the pixel is estimated from the foggy image. By using suitable image restoration software simulations, the fog free output image is obtained. [7]. Fog generally reduces contrast of the image and color of the image. In order to avoid such conditions a novel algorithm is proposed for visibility restoration from a single image. It can be implemented in surveillance camera, intelligent vehicles and remote sensing systems in case of poor weather conditions affected by haze or fog. Image acquisition cannot be performed as it does not deal with grey

level scales of the image. Using the visibility restoration algorithm by Koschmieder, the grey level and color factors can be balanced. Contrast magnification factor which avoids noise factor in the image. As the size of image is increased, the complexity of the image is also increased. Using median filtering the visibility is restored from a single image.

[8]. Forward looking vision system is used to track the lane and estimate the visibility. To estimate the visibility devices like transmissometer's which measure the transmittance and receiver to measure the scattering coefficient in the atmosphere caused due to suspended particles. It requires both transmitter and receiver to measure the back scatter of light due to particles in air. Using RALPH (rapid adopting lateral position handler) the position and curvature of the road including lane markings, road boundaries are detected. The visibility estimation is generated using EOFAST (electro optical and simulation tool software. Live vehicle test is yet to be processed in this method. [9] Reference less perceptual fog density prediction based on FADE which predicts the visibility of fog in a single image. FADE does not only predict fog but processes the entire image for correction. defogging achieves better result for darker image and denser image. Optical model of foggy image due to scattering is complex to remove and the light reflected from the object makes it even more complex.

The fog aware statistical features for prediction of perceptual fog density are done using MSCN coefficients. Both FADE and defogging performances are performed to predict and evaluate the fog content in the image. [10] Using fast edge preserving smoothing approach allows very fast method without high complexity of linear functions having contrast and color fidelity which affects the image visibility. The visibility is restored using estimation of density of skylight, white balance, atmospheric veil are done. The system is fast in removing the atmospheric veil of a foggy image using edge preserving smoothing. It majorly depends on the assumption that produces complexity at the final stages of processing. It is capable

of automatically defog the single image without requiring any additional information about the atmospheric factors.

PROPOSED SYSTEM

Based on the above fog related researches, we can use surrogate-based method to evaluate a regression model for estimating the optical depth D for fog in images. Surrogate model is chosen for minimizing the computational cost and maximizing model accuracy. Fog density or optical depth is not related to the image content, but some fog-relevant features are closely related to it. In order to exclude the interference from image contents on some fog-relevant features, the content-nonspecific fog-relevant features should be selected to obtain the regression model. Based on the error analysis and sensitivity analysis, the accurate fog-relevant features and optical depth can be estimated by the surrogate model. The construction of the surrogate model can be regarded as a non-linear inverse problem. We extract a list of fog-relevant statistical features from foggy images and fit these features as independent variables to the surrogate model of optical depth as an objective function. The dark-channel feature is an informative feature for fog detection and the dark-channel feature is based on the statistics of outdoor fog-free images. Color images can be represented in a more perceptually relevant HSV space and the conversion of an image from RGB to HSV space is performed. Similar to local contrast, the image saturation-value feature degrades exponentially with the optical depth D of scene points in fog. Colorfulness is used as an effective fog-relevant feature to measure the degree of difference between the color and gray of images affected by fog in the scene. The texture in an image is blurred by light scattering in a foggy atmosphere which decreases the image sharpness. . The seven fog-relevant features such as dark channel, local contrast, saturation-value, chroma, variance of chroma, colorfulness, and sharpness are investigated as independent variables to construct the objective function on optical depth. To define the sensitivity of an

independent variable in the surrogate model, the second-order PRG model is used. The flowchart representation of the proposed system is given in the fig.1.

VIDEO CAMERA

The camera is used obtain the recorded outdoor video. The obtained video is moved and stored in the memory unit. The memory unit is functioned to be periodically removing the processed video which avoids memory latency in the system.

VIDEO SPLITTER

The video splitter processes the image into n number of frames so that the system can process the image and make the video output to the drivers. Thus, the obtained foggy image is made ready for processing based on surrogate modeling in optical path.

Figure.1. Flow chart for fog removal algorithm in an image.

SURROGATE MODELLING

In surrogate modeling the visibility defects in the image are identified and evaluated. It has three methods of measuring and evaluating visibility defects

OUTDOOR FOG SENSOR

Outdoor unit regularly sends and receives short infrared optical pulses. Amplitude of the reflected optical pulses is influenced by the reflectance of the

elements in the environment. In addition, the optical sensor is also equipped with temperature and relative humidity sensors. These parameters provide important information and have characteristic values in foggy weather. The sensor is built for the rainy conditions and is shielded from direct sunlight, but allows free movement of fog droplets into the sensor. It is placed outside of the vehicle or any other application based on the requirement.

Figure.2. outdoor fog sensor

INDOOR FOG SENSOR

The outdoor unit contains a microcontroller, which collects the measured data and communicates with the internal unit. Capability ensures seamless firmware updates for the sensor without requiring physical access or additional equipment. The boot loader communicates with the control computer via a serial interface. The user program from the computer will be written into the microcontroller flash memory. This restriction ensures the security and integrity of the firmware update process by limiting it to microcontrollers with the necessary capabilities for self-writing to flash memory. The boot loader itself must be programmed into the initial address space of the flash memory using external programming device. This requirement necessitates compatibility with RS-232 communication ports to facilitate the transfer of measurement data from the external drive to computers running Windows XP or

Vista operating systems. If user computer has an RS-232 serial port it is easy to obtain the output results of fog density.

Fig.3. Indoor fog sensor

PROGRAM SPECIFICATION

The outdoor unit contains a microcontroller, which collects the measured data and communicates with the internal unit. The firmware of the sensor can be updated from the indoor unit, as the outdoor unit has a built-in boot loader system. The boot loader communicates with the control computer via a serial interface. The user program from the computer will be written into the microcontroller flash memory. Boot loader can be used only with those microcontrollers, which is capable to write its owned flash memory. The boot loader itself must be programmed into the initial address space of the flash memory using external programming device. To adopt and save measurement data from the external drive to user computer with the operating software Windows XP or Vista, communication port RS-232 is required. Unlike other platforms in this method, we have used python as the platform.

SENSITIVITY ANALYZER

Measuring device along the propagation path enables accurate monitoring of fog density variations, ensuring precise estimation of fog attenuation for Free-Space Optical (FSO) links. The sensitivity of each independent variable used in learning the model is measured by the variance in the objective function a set of variables can be ranked by their sensitivities. In other words, variables with more contributions to the variability of the objective function comes first. the variables without significantly

affecting the variability of the objective function can be removed from the model regression.

ERROR ANALYZER

The selected accurate surrogate model for optical depth as the objective function is illustrated using 3D contour distribution graph, with a part of the 3D graph shown in Fig. 8(b) and each color contour representing the points with the same specific value of the objective function. The quality of the fit and prediction accuracies of the PRG models are assessed through statistical metrics such as adjusted root mean square error RMSE and adjusted coefficient of multiple data.

FIG.4. principle of fog density measurement

FOG FREE OUTPUT IMAGE

In this work, several sets of experiments are carried out to compare our proposed methods for fog density estimation and image defogging based on surrogate modeling on optical depth with FADE. f values are not similar with each other. Furthermore, all the pixels on each synthetic foggy image should have the same fog density because the optical depths are assigned to be the same for all the pixels in the image. In order to compare the results of fog density estimation and FADE prediction in detail, the 3D graphs of the is required.

WORKING MECHANISM OF THE SYSTEM

Visibility distance depends on the relative sky-height. This concept means that, when there is some fog in a scene and road is segmented, some part of sky gets into

the road part, and the limit between the sky and the road go down. If the image is not foggy, sky and road height on the image are both the same and equals to the vanishing point height, but in a foggy image, apparent sky height is lower than the vanishing point.

This algorithm works with a monocular camera; therefore, 3D structure information is not directly available, but estimation can be made using camera projection equations projection. light sources present in the road because of limited camera dynamic range. If the fog is present, it creates a halo around the light source in the scene due to light scattering produced by the water droplets. In the scene it appears as the luminous shape around the source light and we can observe that the intensity of which decreases slowly away from the light source. Based on the different geometrical parameters the halo around the light source is detected and the output is passed to classification stage to know whether it is a foggy scene or fog free area. The input image is thus segmented into regions where the intensity varies slowly with depth. The regions with constant intensity or fronto- parallel to the image are rejected as well as the tiny regions which are useless. The used criterion for this selection is to select regions with a depth range higher than 10% of the whole image depth range and with an area higher than 2% of the number of image pixels.

This segmentation can also be performed with advantages on a clear day image when a static sensor is used. The segmentation can be also performed on both the image and the depth map, when the depth map is accurate enough. An example for foggy and fog free image estimated by our system is given below FIG.5.

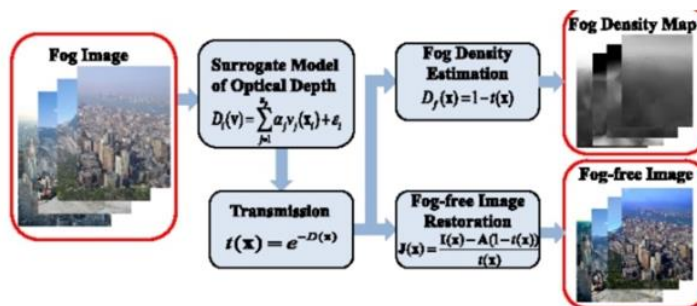

FIG.5. Flow chart for surrogate modelling process

RESULT & DISCUSSION

In this paper, we have proposed a surrogate model on optical depth which is used for effective fog density estimation and image defogging. We have used our surrogate-based method to learn a refined PRG model of optical depth with informative fog-relevant features. Based on the surrogate modelling for optical depth, we have presented a method to represent the level of fog density. It carries out image defogging more effectively. The system offers multiple image processing capability which effectively reduces the execution time of the system. FADE is capable of eliminating noise caused by reflection and scattering, the system accuracy is high compared all other previous methods of fog removal. The simulation part of the system is less complex and less time consuming which makes the system even more efficient.

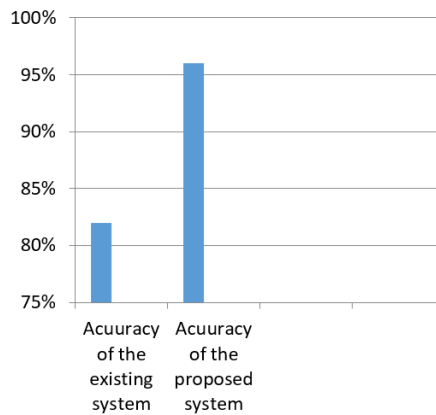

FIG.6. Accuracy difference between existing and proposed system

Experimental result satisfies quantitatively and qualitatively synthesis foggy images and real-world images. Even though the system is a developed one it still produces noise at the output. However, the system accuracy is considerably increased. The future research can focus on various advanced learning models and live video processing.

ABSTRACT

The estimated number of down syndrome individuals in worldwide population is more than 6 million. Children with Down syndrome typically have some delay in physical and mental development which need specialized and personalized efforts to improve their abilities. To address this issue, we aiming to create an intelligent companion app for individuals with Down syndrome, leveraging AI, NLP, and IoT. The app addresses diverse needs such as personalized learning, cognitive training, and promoting independent living. Using ML algorithms, it incorporates emotion recognition for targeted responses based on users' moods. IoT integration ensures safety by tracking locations and facilitating communication with caregivers. This approach, revolutionizes support for this individuals, enhancing communication and emotional well-being.

INTRODUCTION

The Down syndrome, a condition affecting cognitive abilities, is caused by an extra chromosome in the 21st pair. This genetic difference doesn't influence physical development but can impact thinking and learning [1]. Around 6,000 babies are born with Down syndrome in the United States each year, and it's more likely in mothers over 35. People with Down syndrome often face various challenges, such as having a slightly lower IQ, speaking more slowly, and dealing with psychological and social difficulties. These challenges include feelings of anxiety and depression, attention deficit hyperactivity disorder (ADHD) characterized by repetitive movements that affect concentration, and occasional aggressive outbursts. Additionally, some may experience conditions like autism spectrum disorder, including psychosis syndrome. To help address these challenges early on, it's crucial to provide support through services like speech therapy and occupational therapy [3] [4]. To tackle the unique difficulties individuals with Down syndrome encounter, we propose the development of an app equipped with Artificial Intelligence (AI) capabilities. This app goes beyond providing care; it aims to foster inclusiveness, autonomy, and personal growth through a personalized empowerment model. By incorporating cutting-edge technology, this created app can understand and respond to non-verbal cues, making the communication and emotional support more effective. The integration of Internet of Things (IoT) technologies further enhances safety and communication. The envisioned app also contributes to education by offering personalized learning experiences through adaptive AI-driven modules. Machine Learning algorithms within the app adapt to individual learning styles, tailoring cognitive training for each user. This initiative aligns with broader societal goals of creating a more supportive and inclusive environment for individuals with diverse abilities.

In practical terms, the proposed app could have a positive impact on the daily lives of individuals with Down syndrome. For instance, it could help them communicate more effectively, understand and express their emotions, and enhance their safety by utilizing location-tracking features. The AI capabilities could assist in recognizing and addressing specific needs, ensuring a more tailored and responsive approach to support.

Furthermore, educational aspect of app could revolutionize learning experiences for individuals with syndrome. By adapting to their unique learning styles, the AI-driven modules could make education more engaging and effective. This could lead to improved cognitive abilities, contributing to independence and well-being.

In conclusion, the integration of AI in a comprehensive app for individuals with Down syndrome holds tremendous potential in addressing their unique needs and fostering a more inclusive and supportive society. By combining advancements in AI, NLP, and IoT, this initiative represents a noteworthy step towards leveraging technology for the well-being and empowerment of individuals with Down syndrome. Through personalized support, enhanced communication, and adaptive learning experiences, the proposed app could make a meaningful difference in the lives of those with Down syndrome, contributing to a more inclusive and supportive society.

This study of Linnea E Sandstrom, Danielle Harvey (2022) compared mental state language used by 6- to 11-year-old children with Down syndrome to a younger typically developing comparison group matched by nonverbal cognition [2]. They aimed to determine whether mental state language use is delayed in DS relative to developmental expectations, and if there are differences between groups in the association between mental state language and developmental factors. Rate of mental state language use was significantly lower in the group with DS, but the

number of different mental state terms was not significantly different. Patterns of similarity and difference emerged between groups regarding the association between mental state language and other developmental factors.

Highlighting the importance of adaptive technologies in education, the proposed ITS framework aims to assess, evaluate, and provide personalized early intervention services for children with Down syndrome, recognizing the unique requirements that distinguish it from traditional ITSs.

Del Hoyo Soriano et al. (2022) examine the link between expressive language skills and adaptive behavior in Down syndrome (DS) individuals. The study, employing AI-based communication tools, controls for age and cognitive ability. Utilizing

Expressive Language Sampling and Vineland Scales, significant correlations between language measures and adaptive skills are found, implying expressive language's impact on adaptive behavior in DS individuals, irrespective of age and cognitive delays. Longitudinal studies are suggested for deeper insights.

This study of João Antonio Campos Panceri, Éberte Freitas (2019) on MARIA T21, a socially assistive robot, is introduced for therapies in children with Down syndrome and autism spectrum disorder [7]. Utilizing a mini-video projector for Serious Games, developed in Python, the robot enhances engagement in psychomotor, psychosocial, and cognitive therapies. A pilot study involving eight children, despite COVID-19 constraints, demonstrates encouraging outcomes through the Goal Attainment Scale. The study underscores the innovative potential of MARIA T21 and Serious Games as therapeutic tools, paving the way for further validation in larger cohorts for improved healthcare interventions

In this study by Federico Baldo and Allison Piovesan (2023), machine learning techniques [8], specifically random forest and gradient boosting machine models, were applied to analyze clinical records of 106 individuals with Down syndrome (DS) to identify key variables associated with intellectual disability (ID). Utilizing feature selection, data augmentation, and age effect mitigation, the models demonstrated high accuracy in pinpointing factors linked to intellectual functioning, such as hearing, gastrointestinal issues, thyroid state, immune system, and vitamin B12. The results suggest the potential of ML-based models to inform therapeutic targets and improve care pathways for individuals with DS, urging further validation with larger datasets.

demonstrates high usability, satisfaction, and notable improvements in linguistic abilities, particularly in naming, after 6 months of training.

Problem Definition

The frontal lobe, which has some control of intelligence and personality. It also significantly affects character judgment and behavior in daily life. People with Down syndrome who have relatively low level scientific mental development are for this reason deeply influenced by environment tall factors they understand only that which they see or hear at every moment; what people say to them is thus particularly important because it heavily influences In terms of speech development, they are markedly delayed relative to their peers and thus in need of specific support. When it comes to behavior and emotion, children with Down syndrome often suffer from dysthesia (anxiety) or dullthymia (depression). Other complications include Attention Deficit Hyperactive Disorder. They face various challenges in many respects. These include the observable behavioral components such as movement repetition, aggression and autism or even psychosis to social withdrawal that are all three-dimensional char-acters differing according to both time of day and type (sex). Specialists in speech and occupational therapies are called upon to overcome these difficulties so that Down syndrome sufferers may enjoy full-fledged growth. Such interventions are therefore an important step in helping them achieve their full potential by meeting specific needs. Getting involved with such services early on, especially during infancy and childhood extra effective. At this time it can offer an avenue for boosting both physical and intellectual abilities of baby .

Speech therapy can help these children to catch up in terms of verbal expression, developing better language ability and effective communication. Each person's needs are addressed in specific ways, so that fine motor skills and mental abilities can be honed, while independence is encouraged. Providing access to these services early on forms a key element of the support structure for persons with Down syndrome, providing a firm foundation from which they learn. In fact, the special characteristics of Down syndrome require selective approaches to interventions and services - especially in early years. Not only can these interventions help children overcome challenges, they represent a vital opportunity to open up untapped potential and push towards better physical or mental fitness; in fact this is the best way of promoting optimal health for people with Down syndrome.

FRAMEWORK FOR DEVELOPMENT

Solution Outline

Through this approach, the app aims to enhance the abilities of these individuals, by helping their unique needs. Additionally, it introduces a feature that allows parents and caregivers to actively monitor both the individuals and their surroundings [2]. This is made possible by integrating Internet of Things (IoT) technology, creating a collaborative system that not only

Figure 2. Block diagram

supports personal development but also ensures a more connected and monitored environment for the well-being of individuals with Down syndrome.

The above block diagram outlines how our app utilizes the power of machine learning and natural language processing to personalize support for down syndrome individuals.

Proposed Architecture

This app stands as a versatile and personalized support system crafted specifically for individuals with Down syndrome, harnessing cutting-edge technologies to meet their unique needs. Machine learning (ML) models undergo training to adeptly recognize speech patterns, interpret emotional cues, facial expressions, and tones of voice, ensuring precise comprehension of user inputs. The app, responsive to voice commands, not only answers questions and provides information on diverse topics but also adapts to each user's distinct capabilities, learning style, and preferences. The ML algorithms propel personalized learning programs [4] [10], encompassing interactive games [9], cognitive exercises, and educational content tailored to individual needs. The app diligently monitors progress, delivers feedback, [5] and dynamically adjusts difficulty levels to provide continuous challenges and support for the user's development.

Beyond education, the app takes a holistic approach by evaluating the user's abilities at the outset, tailoring subject modules based on their intelligence quotient level. Delving into emotional well-being, the app extends support through comforting messages, positive reinforcement, and virtual companionship. It fosters social interaction [3] by enabling seamless communication with family, friends, and support networks through video calls and messaging functionalities. Integrated with Internet of Things (IoT) devices, the app contributes to establishing a safe living environment. It effortlessly connects to smart home systems, empowering users to control lights, temperature, and security features through either voice commands or

a user-friendly interface. Notably, the app incorporates location tracking functionality, offering caregivers a valuable tool to ensure user safety and receive alerts in cases of emergencies or irregular behaviour [2].

Emphasizing the utmost importance of privacy and security, the app is meticulously designed to adhere to stringent rules, guidelines, and encryption standards, safeguarding sensitive information. The core objective is to prioritize the well-being and independence of individuals with Down syndrome, ensuring a supportive and secure technological framework that enhances their overall quality of life.

Technological framework

The flow diagram represents the actual working flow of app by use of various advanced technologies like artificial intelligence and related technologies.

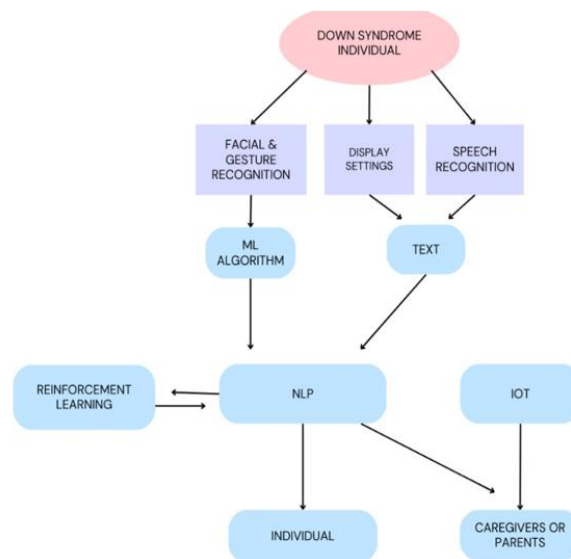

Figure 3. Flow diagram of working principle

Technological Stack

Technology used: ML, RL, NLP, IOT

Camera: To capture responses [facial emotion, body gesture]

ML: Used for detection and identification of emotions and body gesture (CNN)

RL: Adapt to user's characteristics, offers personalized responses like interactive games, cognitive and vocal exercises, educational content etc.,

NLP: Integrated with RL algorithms and chatbot for speech recognition and to sound appropriately.

IOT: used for tracking location and ensure safety of individuals.

Games: To improve their cognitive and intellectual ability in playful way. Satisfying games to reduce stress.

Procedure of implementation

The processes involved are

Step 1: Identify and capture verbal and non-verbal communication modalities [3] by sensors (wearable devices, cameras) using CV and ASR. Train an emotion recognition model using ML/ DL algorithms [10].

Step 2: The emotional recognition model provides predictions, select the dominant emotion based on a threshold or the highest probability.

Step 3: It is further processed using NLP to enhance understanding of the user's emotional context during interactions with app [3]. This integration allows system to respond with empathy and provide appropriate emotional support.

Step 4: Define mappings between recognized emotions and text representations by predefined mapping or lookup table. Design a feedback system with appropriate text, images, or sounds using NLG.

Step 5: RL algorithms learns from user actions and provide appropriate rewards or feedback to reinforce positive behaviors. By incorporating RL, it can continuously improve its recommendations, adjust difficulty level of activities,[5] optimize its responses to suit up references and learning style.[1]

By adjusting weights- quality, relevance or contextual appropriateness of the generated responses can be improved. RL can explore different response generation strategies and exploit most effective ones based on learned rewards and user feedback.

The RL process is iterative, allowing system to continuously learn and refine its response generation. As users interact with system, RL updates NLG model based

on collected feedback, leading to more personalized and contextually appropriate responses over time.

Create customized interfaces such as display settings, text, images, other visual content associated with recognized emotions on the device's screen (touchscreens, large buttons, etc.). Collaborate with caregivers, educators, and therapists for input and refinement, location tracking functionality and to monitor irregular behavioral patterns [2].

RESULTS AND DISCUSSION

The below graph shows expected intellectual and cognitive development of down syndrome individuals by usage of app over a period of time.

Figure 4. Graph

The app, integrating ML, RL, NLP, and IoT [10] for Down syndrome patients, is made to make significant role in enhancing the IQ levels of individuals over the years. ML models will accurately recognize speech patterns and emotional tones, enabling natural conversations and also recognizes information portrayed by user by capturing body/sign language. The app will respond to voice commands, suggesting personalized learning programs [5] based on intelligent quotient level found by usage and assessment and tracking progress over time. Emotional support, social interaction, and safety standards in everyday living will be maintained through consoling messages, video calls, and IoT-integrated security systems respectively. Utilizing CNNs for emotion detection, RL for adaptive learning, and

NLP for speech recognition, among other technologies, the app will include cognitive development games designed to contribute to relaxation and overall well-being. Iterative refinement through RL processes, informed by user feedback over time, is expected to lead to observable improvements in the IQ levels [6] of individuals with Down syndrome with respect to time duration in years. Ongoing collaboration with caregivers [2] and the recommendation for further validation with a diverse user population will ensure that the evolving needs of individuals are effectively met by this innovative app. It is proved that this application exemplifies how advanced technology could improve lives of Down syndrome patients today.

FUTURE ENHANCEMENT

Utilize Augmented Reality or Virtual Reality scenarios to simulate social situations and provide training for individuals with Down syndrome to improve their social interaction skills. Virtual avatars or characters will be made to display emotions, and individuals can practice responding appropriately through dialogues or interactions. This helps individuals to be more familiar with handling emotions with ordinary people. AR/VR can offer a safe and controlled environment for individuals to learn and refine their social skills without real-world pressures like isolation, discriminated handling, etc.

CONCLUSION

In conclusion, this app integrates various advanced technologies to provide comprehensive support for individuals with Down syndrome. Through recognizing speech patterns and interpreting emotions, facial expressions and tone of voice, the application offers personalized learning, interactive games and cognitive exercises. It adapts in difficulty levels dynamically according to progress stored by it while offering emotional well-being through positive reinforcement and virtual companionship. Making video calls or messaging to socialize as well as connecting to IoT devices for safe living environments are also services offered by it.

The app's procedural framework prioritizes data privacy that includes emotion recognition training, NLP integration as well as iterative RL in order to improve continuously. In addition, customized interfaces and collaborative development with caregivers are aimed at enhancing user experience thereby making this application a promising and inclusive tool [1] for people with intellectual plus developmental disabilities revealing how advanced technologies can change lives.

ABSTRACT

The IoT-based Smart Alert Flood and Earthquake Monitoring and Early Warning System addresses the urgent need for advanced disaster management solutions. Leveraging Internet of Things (IoT) technology, this system offers real-time monitoring and predictive capabilities for flood and seismic events. Key features include continuous data collection, advanced analytics, and automated alert mechanisms. This paper provides an overview of the system architecture, including sensor deployment and data processing techniques. Performance evaluation metrics are discussed, along with results from simulated scenarios. The study concludes with implications for future research and implementation strategies.

KEYWORDS

IoT, SMART ALERT, FLOOD MONITORING, EARTHQUAKE MONITORING, EARLY WARNING SYSTEM, DISASTER MANAGEMENT

INTRODUCTION

Natural disasters like floods and earthquakes present significant challenges to communities worldwide. Early warning systems play a crucial role in mitigating the impact of such events by providing timely alerts and enabling proactive response measures. The IoT-based Smart Alert Flood and Earthquake Monitoring and Early

Warning System is designed to enhance the effectiveness of disaster management efforts through advanced technology and real-time data analysis.

SYSTEM ARCHITECTURE

The architecture of the IoT-based Smart Alert System comprises sensor nodes deployed in flood-prone and seismic areas, connected to a central monitoring and control unit via wireless communication networks. These sensors collect data on environmental parameters such as water levels, seismic activity, and weather conditions. The central unit processes the incoming data using machine learning algorithms to detect patterns indicative of impending disasters.

DATA PROCESSING AND ANALYSIS

Upon receiving sensor data, the central unit applies various data processing techniques to extract meaningful insights. Machine learning algorithms are employed for predictive modeling, enabling the system to anticipate flood and earthquake events based on historical data and real-time observations. The accuracy of predictions is continuously refined through iterative learning processes.

ALERT MECHANISMS

When the system detects potential threats, it triggers automated alert mechanisms to notify relevant stakeholders. Alerts are delivered through multiple channels, including mobile applications, SMS, email, and sirens, ensuring that residents, authorities, and emergency responders receive timely notifications. The system allows for customizable alert thresholds based on the severity of the detected event, enabling appropriate response actions to be initiated.

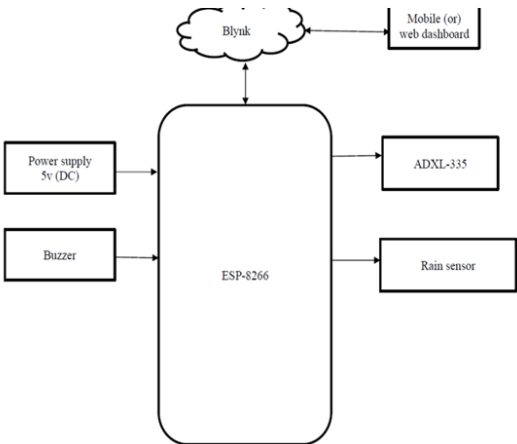

FIGURE 2. Block diagram for earthquake detection

PERFORMANCE EVALUATION

Performance evaluation of the IoT-based Smart Alert System involves testing its effectiveness in detecting and predicting flood and earthquake events. Simulated scenarios are used to assess the system's response time, accuracy of predictions, and reliability of alert mechanisms. Results from these tests provide valuable insights into the system's capabilities and areas for improvement.

CONCLUSION

The IoT-based Smart Alert Flood and Earthquake Monitoring and Early Warning System represents a significant advancement in disaster management technology. By leveraging IoT technology, real-time data analysis, and predictive modeling, the system offers a proactive approach to mitigating the impact of natural disasters. Continued research and development efforts are needed to enhance the system's capabilities and ensure its widespread adoption in communities vulnerable to floods and earthquakes.

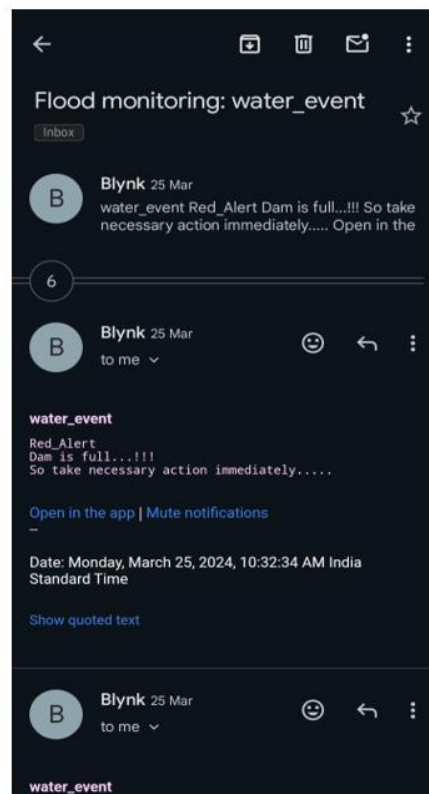

RESULT AND DISCUSSION

The data collection phase of the project involved the deployment of IoT sensors for flood and earthquake monitoring. These sensors gathered a wealth of information, including water levels, seismic activity, and environmental parameters. Analysis of the collected data revealed notable patterns and trends, such as increased water levels preceding flood events and seismic disturbances preceding earthquakes. Statistical analysis further corroborated these findings, providing quantitative insights into the behavior of the monitored phenomena.

In terms of system performance, the IoT-based early warning system demonstrated commendable efficacy. Real-time monitoring capabilities allowed for swift detection of flood and earthquake events, with alerts generated promptly upon detection. Metrics such as response time and accuracy of predictions showcased the system's reliability in providing timely warnings to at-risk communities. Comparisons with traditional monitoring methods highlighted the superiority of the IoT-based approach, particularly in its ability to deliver actionable insights in a timely manner. The early warning alerts issued by the system proved to be invaluable in mitigating the impact of natural disasters. Examples of alerts provided ample evidence of the system's ability to provide advance notice of impending flood and earthquake events, enabling authorities and individuals to take proactive measures to protect life and property. The timely dissemination of warnings

significantly enhanced preparedness and response efforts, potentially saving lives and minimizing damage.

The project underscored the transformative potential of IoT technology in disaster management and early warning systems. By leveraging IoT sensors for real-time monitoring, the system demonstrated a marked improvement over traditional methods, offering enhanced accuracy and responsiveness. However, challenges such as sensor reliability and data transmission issues necessitated careful consideration during implementation. Addressing these challenges will be crucial for ensuring the long-term viability of IoT-based early warning systems. Integration with existing disaster management frameworks emerged as a key consideration for maximizing the impact of the IoT-based system. Seamless integration with governmental alert systems and disaster response protocols can streamline communication and coordination during crisis situations, facilitating more effective disaster response efforts. Exploring avenues for interoperability and collaboration will be essential for realizing the full potential of the IoT-based early warning system. Looking ahead, the project identified several areas for future research and development. Enhancements to sensor technology, data analytics algorithms, and communication protocols hold promise for further improving the accuracy and reliability of early warning systems. Additionally, research into the social and behavioral aspects of disaster preparedness and response can inform the design of more effective risk communication strategies. By continuously innovating and refining IoT-based solutions, we can better equip communities to anticipate, mitigate, and respond to the ever-present threat of natural disasters.

ABSTRACT

Forest 4.0 represents a groundbreaking approach to forest monitoring and prevention by harnessing the power of Wireless Sensor Networks (WSNs) and the Internet of Things (IoT). Through the integration of LoRa transceiver modules with Arduino micro-controllers, this system enables seamless data collection in dense forest environments. Leveraging long-range LoRa communication and cloud connectivity via Wi-Fi, Forest 4.0 provides real-time insights into forest health and environmental conditions. The integration with the Blynk IoT platform facilitates intuitive visualization and analysis, empowering stakeholders to make informed decisions for sustainable forest management.

INTRODUCTION

The Forest 4.0-based Wireless Sensor Network and IoT combined Forest Monitoring and Prevention System represents a groundbreaking integration of cutting-edge technologies to address the critical challenges of forest management. At the heart of this innovative project is the utilization of LoRa (Long Range) transceiver

modules, specifically the SX1278, to establish a robust wireless communication network in a forest environment. Deployed as a transmitter, the LoRa module is seamlessly integrated into an Arduino Nano micro controller strategically positioned within the forest. The Arduino Nano serves as the nerve center, collecting and monitoring essential environmental data vital for effective forest management. The sensor suite includes real-time measurements of air temperature, air and pressure are monitored. On the receiving end, another LoRa module captures the transmitted data, forming a wireless sensor network that acts as a vigilant guardian of the forest ecosystem. This information is then relayed via Wi-Fi to the Blynk IoT cloud platform, where it is presented in a user-friendly interface. This cloud-based solution empowers users to remotely monitor the forest conditions from anywhere in the world, providing real-time insights into the health and well-being of the ecosystem. The Forest 4.0 system is designed not only for monitoring but also for proactive prevention measures. By leveraging the Blynk IoT cloud, users can set up automated actions triggered by predefined thresholds. For instance, if the system detects unfavourable conditions such as high temperatures or low soil moisture levels, it can autonomously activate the water pump to mitigate potential risks to the forest.

LITERATURE SURVEY

Forest monitoring systems leveraging Wireless Sensor Networks (WSN) and Internet of Things (IoT) are rapidly evolving, propelled by advancements in technology. Key to these systems is the integration of LoRa transceiver modules, such as the SX1278, with Arduino micro controllers, enabling robust data acquisition and transmission even in dense forest environments. These systems incorporate environmental sensors to monitor crucial parameters like temperature, humidity, and soil conditions, providing valuable insights into forest ecosystems. LoRa technology facilitates long-range communication within the forest, overcoming traditional connectivity challenges.

HARDWARE IMPLEMENTATION

Arduino nano

The Arduino Nano is a compact, versatile, and user-friendly micro controller board that belongs to the Arduino family. Designed as a small form-factor version of the popular Arduino Uno, the Nano is particularly well-suited for projects with space constraints. It features the ATmega328P micro controller, the same chip found in the Uno, providing a powerful and flexible platform for a wide range of applications.

The Nano's support for communication protocols such as I2C, SPI, and UART further expands its capabilities, enabling seamless integration with a wide range of peripherals, from sensors to displays. This versatility makes it suitable for prototyping projects, building embedded systems, and undertaking DIY electronics endeavors. Whether powered through USB or an external source, the Nano offers flexibility to adapt to different usage scenarios, making it an invaluable tool for experimentation and innovation in the world of electronics.

Node mcu

The ESP8266, a versatile Wi-Fi enabled micro controller designed by Espressif Systems, serves as the backbone for countless Internet of Things (IoT) applications. Its integration of a powerful 32-bit micro controller with a Wi-Fi radio makes it an ideal choice for connected devices. Building upon the ESP8266's capabilities, the NodeMCU development board provides a user-friendly platform for prototyping IoT projects. With built-in Wi-Fi capabilities and easy access to the ESP8266's pins, NodeMCU simplifies the development process. Additionally, the pre-installed Lua

scripting language streamlines code writing and uploading. One notable feature of the ESP8266 is its Secure Digital Input/output (SDIO) Interface, supporting both 4-bit 25 MHz SDIO v1.1 and 4-bit 50 MHz SDIO v2.0 standards. This interface enables direct interfacing with SD cards, facilitating data storage and logging in IoT applications. Parameters. With adaptability to different frequency bands, LoRa modules comply with regulatory standards and adapt to local requirements. Overall, the LoRa module's working model ensures efficient data transmission over long distances with a focus on power efficiency and adaptability to diverse operational scenarios.

DHT-11

The DHT-11 sensor module is a popular and cost-effective device widely used for measuring temperature and humidity in various applications. Featuring a digital output, it is known for its simplicity and ease of use. The module integrates a DHT-11 sensor, a capacitive humidity sensor, and a thermistor for temperature measurement. Its compact design and low power consumption make it suitable for both hobbyist projects and commercial applications as shown in Fig 3.

The DHT-11 sensor utilizes a one-wire communication protocol, enabling seamless integration with micro controllers like Arduino and Raspberry Pi. With a humidity measurement range of 20-80% and a temperature range of 0 to 50 degrees

Celsius, the sensor module provides reliable data for climate monitoring, environmental control, and home automation. Despite its limitations, the DHT-11 sensor module remains a popular choice for educational projects, weather stations, and applications where moderate accuracy is sufficient. Its affordability, ease of use, and compatibility with various platforms contribute to its widespread adoption in the maker community and beyond.

LoRa SX1278

The LoRa module, like the SX1278, operates on the principle of spread spectrum modulation, specifically using chirp spread spectrum (CSS) technology. In transmission, data from sensors is collected by the Arduino micro-controller and sent to the LoRa module for modulation. The module generates chirp signals, where the signal frequency continuously varies, and transmits this over the airwaves. On the receiving end, another LoRa module captures the chirp signal and demodulates it to extract the original data as given Fig 4. LoRa's spread spectrum modulation enables reception of weak signals in noisy environments. Its long-range communication capability allows transmission over several kilometers, even in obstructed environments like

Fig 4 LoRa module

Relay module

The 5V relay module is an electronic device designed for interfacing low-voltage micro controllers or digital circuits with high-voltage or high-current devices, enabling seamless control over electrical appliances, industrial equipment, and other electro mechanical systems. This module typically consists of a relay, a driver circuit, and supporting components, encapsulated on a compact PCB (Printed Circuit Board). At the core of the 5V relay module is an electromagnetically relay, which serves as a switch that can control the flow of electrical current. The relay is activated by a small current from the micro controller, and when energized, it can handle higher currents and voltages, allowing the module to control devices that might otherwise be incompatible with the low-voltage logic of micro controllers as given Fig 5.

The 5V operating voltage of the relay module makes it compatible with common micro controllers like Arduino and Raspberry Pi, simplifying integration into various electronic projects. The module typically features multiple input and output pins, making it versatile for different applications. Additionally, the relay often has multiple poles, allowing it to control multiple circuits simultaneously.

Capacitive soil moisture sensor

The capacitive soil moisture sensor is an electronic device designed to measure the moisture content in soil by utilizing the principle of capacitance. This type of sensor is widely used in agriculture, gardening, and automated irrigation systems to monitor and control the watering of plants based on soil moisture levels. The

capacitive soil moisture sensor provides a more accurate and reliable measurement compared to traditional resistive soil moisture

micro controller, typically using the Dallas Semiconductor 1-Wire communication protocol. This protocol allows for easy integration into micro controller-based projects, with each sensor having a unique 64-bit ROM code for identification in a multi-sensor network. One of the notable dense forests. LoRa modules are designed for low power consumption, suitable for battery-operated devices in remote sensors. At its core, the sensor consists of two conductive electrodes that act as capacitor plates. When inserted into the soil, the moisture content in the soil influences the dielectric constant, affecting the capacitance between the electrodes. The sensor measures this capacitance and translates it into a moisture level reading as shown in Fig 6.

One of the key advantages of capacitive soil moisture sensors is their sensitivity to changes in soil moisture across a wide range. They can detect variations in moisture content more precisely than resistive sensors, providing a more nuanced understanding of soil conditions. Additionally, capacitive sensors are less prone to corrosion since they do not have exposed metal elements. Furthermore, capacitive soil moisture sensors are known for their low power consumption, allowing for extended periods of operation on battery-powered systems. This efficiency is especially beneficial in remote or off-grid applications.

When using capacitive soil moisture sensors, it's important to consider factors such as sensor calibration for specific soil types and the depth at which the sensor is inserted into the soil. Calibration ensures accurate moisture readings tailored to the characteristics of the soil in which the sensor is deployed

DS18B20

The DS18B20 is a digital temperature sensor known for its precision, ease of use, and one-wire communication interface. Manufactured by Maxim Integrated, this sensor is widely used in various applications where accurate temperature monitoring is essential. The DS18B20 operates based on the 1-Wire protocol, allowing multiple sensors to be connected to a single micro controller pin, simplifying wiring and making it suitable for applications like environmental monitoring, industrial control systems, and home automation.

The sensor is encapsulated in a small, waterproof stainless-steel package, enabling it to be deployed in harsh environments or submerged in liquids. Its versatile design, combined with its temperature range of -55°C to $+125^{\circ}\text{C}$, features of the DS18B20 is its high accuracy, with temperature resolution configurable down to 9, 10, 11, or 12 bits. This allows users to choose between lower resolution for faster readings or higher resolution for more precise temperature measurements as shown in Fig 7.

The sensor is powered through the same single-wire interface used for communication, simplifying the wiring and reducing the need for additional power lines. Its low power consumption makes it suitable for battery-powered applications, and the ability to put the sensor into a low-power sleep mode further enhances its energy efficiency.

O-led display

OLED displays typically have multiple pins used for different functions and can communicate with micro controllers using standard protocols such as I2C (Inter-Integrated Circuit) or SPI (Serial Peripheral Interface).

The function pins on an OLED display may include:

Power pins: These pins provide power to the display, typically including VCC (power supply voltage) and GND (ground).

Data pins: These pins are used to transmit data to and from the display. For example, in I2C communication, there are SDA (data) and SCL (clock) pins, while in SPI communication, there may be MOSI (Master Out Slave In), MISO (Master In Slave Out), SCK (clock), and CS (chip select) pins.

Control pins: These pins are used to control various aspects of the display, such as turning it on/off or resetting it. They may include pins like DC (data/command mode select) and RST (reset).

By connecting the appropriate pins to a micro controller and using the correct protocol, developers can easily send commands, data, and graphics to the OLED display, allowing for the creation of various applications and user interfaces.

Fig 8 Oled Display

makes the DS18B20 suitable for a wide range of temperature sensing applications.

SOFTWARE DESCRIPTION

A Arduino IDE

Arduino IDE is short for Integrated Development Environment - it's the official software from Arduino.cc, used primarily for writing, compiling, and uploading

code onto Arduino devices. It's open source and supports almost all Arduino modules, making it easy to install and start coding on the go. Compatible with MAC, Windows, and Linux, it runs on the Java Platform and offers built-in functions and commands crucial for debugging, editing, and compiling code. Various Arduino modules are available, such as Arduino Uno, Arduino Mega, Arduino Leonardo, Arduino Micro, each featuring a micro controller that's programmed to interpret and execute code. The main code, also known as a sketch, created on the IDE platform will ultimately generate a Hex File which is then transferred and uploaded in the controller on the board. The IDE environment mainly contains two basic parts: Editor and Compiler where former is used for writing the required code and later is used for compiling and uploading the code into the given Arduino Module. This environment supports both C and C++ languages.

BYLNK

Blynk app is user-friendly and easy to set up. The app has a drag-and-drop interface that allows users to quickly and easily create custom control panels for their

connected devices. Universal compatibility: Blynk app is compatible with a wide range of micro controllers and single-board computers, including Arduino, Raspberry Pi, ESP8266, and more. Cloud connectivity: Blynk app works with Blynk Cloud, a cloud-based infrastructure that allows users to control and monitor their devices from anywhere in the world, as long as they have an internet connection as shown in Fig 10.

Security: Blynk app provides secure communication between devices and the cloud server using industry-standard encryption protocols, keeping user data and devices safe from hackers. Low cost: Blynk app is a low-cost solution for IoT projects, as it eliminates the need for users to purchase expensive hardware and sensors. Users can simply connect their existing devices and sensors to the app. Flexibility: Blynk app is highly flexible and customizable, allowing users to create their own custom widgets and control panels, and to integrate third-party APIs and services.

Fig 10 Blynk Software.

Working of Blynk

Blynk serves as an IoT platform accessible through iOS or Android smartphones, facilitating remote control of devices like Arduino, Raspberry Pi, and NodeMCU over the internet. It enables users to design a graphical interface or human-machine

interface (HMI) by configuring widgets and assigning appropriate addresses, thus streamlining interaction with connected devices.

fig 11. Receiver block

The primary objective of the proposed Forest 4.0-based monitoring and prevention system is to harness the capabilities of wireless sensor networks and IoT technologies to create an intelligent and efficient solution for forest management as shown in Fig 11. At the heart of this innovative system is the LoRa SX1278 transceiver module, which acts as a transmitter installed on an Arduino Nano microcontroller strategically positioned within the forest. This transmitter is equipped to capture crucial environmental parameters such as air temperature, air humidity, soil temperature, soil moisture, and is also linked to a water pump designed for forest plant prevention system.

HARDWARE IMPLEMENTATION

An Improved Forest Fire Monitoring Algorithm With Three-Dimensional Outs

Forest fires can destroy millions of acres of land at shockingly fast speeds. The forest fire points identification algorithm is the most critical step in the forest fire monitoring process. Most traditional forest fire monitoring methods use fixed thresholds, ignoring background pixels, and have low recognition rates, which could lead to many problems, such as false reporting and low recognition rate. This paper proposes and tests an adaptive forest fire points identification algorithm using

Himawari-8 data. By calculating the three-dimensional histogram of brightness temperature, an adaptive threshold that can automatically identify potential forest fire points is obtained. Based on this three-dimensional Otsu method, the contextual test algorithm has also been adopted to specify forest fire points. The experimental results show that the omission rate of the improved algorithm is about 10% lower than that of the previous algorithm in small-scale fire incidents. The improved algorithm can quickly and effectively extract fire point information, and it is also sensitive to small and low-temperature fires, which provides an efficient means for monitoring fire disasters.

The LoRa SX1278 transmitter serves as the linchpin for the wireless communication network, facilitating the seamless transfer of real-time data over long distances, a critical feature for expansive forest areas. This transmitted data is then received using another LoRa module, forming an interconnected wireless sensor network that effectively captures the dynamic conditions of the forest ecosystem. The utilization of LoRa technology ensures low power consumption and wide coverage, making it ideal for remote and challenging environments like forests as shown in Fig 12. The integration of Blynk IoT cloud services into the system further elevates its functionality. The LoRa-received data is transmitted over WiFi to the Blynk IoT cloud, allowing for remote monitoring and control from any location worldwide. This cloud-based interface provides a comprehensive and user-friendly platform where stakeholders, including forest managers, researchers, and authorities, can access real-time information on the monitored parameters.

The overarching goal of this Forest 4.0 system is to enable proactive forest management by automating preventive actions based on the gathered data. For instance, the system can trigger the water pump to irrigate the forest in response to low soil moisture levels, mitigating the risk of drought-induced stress on plant life. Additionally, the ability to remotely monitor air and soil conditions empowers

stakeholders to make informed decisions, facilitating early intervention in the case of potential threats such as wildfires or disease outbreaks.

In summary, the main objectives of this Forest 4.0-based monitoring and prevention system include the establishment of a robust wireless sensor network using LoRa technology, real-time data acquisition of crucial environmental parameters, seamless data transmission to the Blynk IoT cloud for global accessibility, and the implementation of automated preventive actions to ensure the sustainable management and protection of forest ecosystems. This holistic approach aims to revolutionize forest monitoring, making it not only technologically advanced system

Interference Cancellation for LoRa Gateways and Impact on Network Capacity

A second generation LoRa receiver that implements Successive Interference Cancellation (SIC) and time synchronization to improve the performance of LoRa gateways. Indeed, the chirp spread spectrum modulation employed in LoRa experiences very high capture probability, and cancelling the strongest signal in case of collisions can significantly improve the cell capacity. An important feature of LoRaSyNc is the ability to track the frequency and clock drifts between the transmitter and presumably tailored to meet the specific needs of such projects, likely offers a suite of tools designed to streamline data collection, facilitate in-depth analysis, and enhance visualization of findings

where the use of low-cost oscillators on end-devices can lead to inaccuracies. To validate the effectiveness of LoRaSyNc in handling collisions, we developed a receiver prototype using software-defined radios. We conducted numerous experiments in various realistic scenarios and compared our receiver's performance with that of commercial gateways. Furthermore, we simulated a cellular deployment involving one or more gateways, demonstrating that our proposed scheme enhances performance by nearly 50% compared to traditional receivers."

CONCLUSION

The integration of a wireless sensor network and IoT in a Forest 4.0-based monitoring and prevention system represents a cutting-edge approach to environmental management. The utilization of LoRa transceiver modules, specifically the SX1278, enhances communication capabilities in remote forest areas. Implemented on an Arduino Nano micro controller, the LoRa SX1278 acts as a transmitter, facilitating the seamless transmission of crucial data such as air temperature, air humidity, soil temperature, soil moisture, and the status of a water pump designated for forest plant prevention.

Utilizing an innovative wireless sensor network, this system employs LoRa technology to efficiently transmit forest data. At the receiving end, the data is seamlessly integrated, creating a comprehensive forest monitoring solution. Leveraging the Blynk IoT cloud, users can remotely monitor vital parameters in real-time from anywhere in the world. This cloud-based approach offers a user-friendly interface for visualizing and analyzing data, empowering stakeholders with global accessibility.

ABSTRACT

In the increasingly interconnected landscape of federated cloud services, ensuring the secure exchange of data among different entities is a critical concern. This paper presents a novel approach to authentication using a combination of cryptography and machine learning techniques. The proposed method integrates an encryption algorithm for secure data transmission and a corresponding decryption algorithm for data retrieval. Additionally, machine learning algorithms, specifically ensemble Voting Classifier, are employed for enhanced authentication and threat detection in real-time. By leveraging cryptographic principles, including encryption and decryption algorithms, the proposed system ensures that data shared within federated cloud environments remain protected from unauthorized access or tampering. Moreover, the integration of machine learning algorithms adds an extra layer of security by enabling proactive threat detection and mitigation. To validate the efficacy of the proposed approach, performance evaluations are conducted using benchmarks from reputable cybersecurity datasets and analysis tools. The results demonstrate the effectiveness of the system in terms of security features and communication efficiency compared to existing methods. Overall, this work

contributes to advancing the field of secure data-sharing in federated cloud services environments by combining cryptography and machine learning techniques to provide robust authentication mechanisms, thereby addressing the growing challenges of cybersecurity in distributed computing environments.

INTRODUCTION

By utilizing both hardware and software services from various cloud service providers, corporate organizations offer e-services such as e-business, online banking, e-commerce, e-finance, and e-marketing to clients worldwide (Krombholz et al., 2015; Saxena & Saxena, 2015; Saxena & Singh, 2020a). Securing online communications between senders and receivers has become imperative to ensure secure and efficient online commerce or data collaboration. A robust mutual authentication mechanism is necessary to facilitate protected key exchange and secure session establishment during online data sharing (Li, Xuelian, et al., 2019; Li, Yang, et al., 2019). For security and scalability reasons, businesses distribute their data across multiple cloud servers (Saxena et al., 2018). Consequently, many clouds collaborate to provide IT services to these firms, which have branch offices dispersed worldwide

(Li et al., 2012; Saxena et al., 2016; Saxena & Saxena, 2015).

In the past year, 47% of firms experienced security attacks or failed compliance audits, according to the Thales Report 2020. Additionally, a multi-server environment has introduced complexities and vulnerabilities. In 2017, Equifax, the largest U.S. credit bureau, exposed the private information of 147.9 million clients due to an application vulnerability, as reported by Armerding (2018). Numerous researchers have proposed security solutions to address flaws in online data exchange, including secure authentication protocols, access control schemes,

protected credential storage, secure secret key sharing, and secure data storage and sharing (Li, Xuelian, et al., 2019; Li, Yang, et al., 2019; Saxena et al., 2018; Saxena & Singh, 2020b).

To ensure comprehensive security against user anonymity attacks, some security measures include a dynamic identity-based mutual authentication protocol employing smart cards in a multi-server system (Li et al., 2012). Online communication in smart grids is safeguarded by creating public and private keys using ECC (Abbasinezhad-Mood & Nikooghadam, 2018; Mahmood et al., 2018). Mutual authentication is essential for users to share data and protect themselves against frauds such as man-in-the-middle attacks, key loggers, and user anonymity. Typically, mutual authentication involves three phases: registration, login or authentication, and password changing. During registration, clients establish their authentic identity or account at a reputable cloud server. Secret key sharing occurs during the authentication process to establish a specific session (Abbasinezhad-Mood & Nikooghadam, 2018; Balaji et al., 2019; Mahmood et al., 2016, 2018; Nimmy & Sethumadhavan, 2014). Clients can update security measures on their identities at the cloud server during the password change phase.

The objective is to develop a secure authentication mechanism for data exchange in federated cloud services by integrating cryptography and machine learning to ensure data confidentiality and integrity. In federated cloud environments, ensuring secure data exchange among entities poses challenges due to potential security breaches. Existing methods often lack real-time threat detection and mitigation capabilities. Therefore, there is a need to develop an authentication system that combines cryptographic techniques with machine learning algorithms to enhance security, detect threats in real-time, and ensure the integrity of shared data.

LITERATURE SURVEY

In the cybersecurity domain, ensuring secure communication and authentication mechanisms is crucial, especially concerning emerging technologies like federated

cloud services, smart grids, vehicular ad hoc networks, and mobile social networks. This literature review aims to investigate recent advancements and research endeavors in developing robust authentication schemes using cryptography, machine learning, and privacy-preserving techniques.

Abbasinezhad-Mood and Nikooghadam (2018) proposed a lightweight authentication scheme based on security-enhanced elliptic curve cryptography (ECC) tailored for smart grid communications. Their focus was on enhancing security while accommodating the resource limitations of smart grid devices. By utilizing ECC, their scheme provided strong security features suitable for the smart grid environment [1].

In the realm of malware detection, Arash and Kadir (2017) introduced a network-based framework for detecting and characterizing Android malware. Their framework emphasized the significance of network-based detection methods in combating the evolving landscape of Android malware. Through the analysis of network traffic patterns and behavioral characteristics, their framework aimed to improve the detection and characterization of Android malware[2].

Data breaches continue to present significant challenges in cybersecurity. Armerding (2018) underscored the severity of data breaches in the 21st century by compiling a list of major incidents. This compilation serves as a reminder of the critical importance of robust authentication and security measures in preventing and mitigating data breaches[3].

Balaji, Sukumar, and Parvathy (2019) proposed an enhanced dual authentication and key management scheme for authenticating data in vehicular ad hoc networks (VANETs). VANETs require secure authentication mechanisms to ensure the integrity and authenticity of exchanged data. Their scheme addressed these needs by incorporating dual authentication and efficient key management techniques, bolstering the security of VANETs [4].

Bilogrevic et al. (2016) introduced a machine-learning based approach for privacy-aware information-sharing in mobile social networks. Privacy concerns are paramount in mobile social networks where users share personal information. Their approach utilized machine learning algorithms to analyze user preferences and behavior while preserving privacy, aiming to mitigate privacy risks in mobile social networks [5].

Privacy-preserving techniques play a vital role in safeguarding sensitive information. Doderio et al. (2019) proposed a privacy-preserving reengineering approach for model-view-controller (MVC) application architectures using linked data. Their approach aimed to enhance privacy protection in web applications by leveraging linked data principles, integrating privacy-preserving mechanisms into MVC

architectures to mitigate privacy risks associated with web applications [6].

Regarding smart card authentication, Fan, Chan, and Zhang (2005) presented a robust remote authentication scheme for smart cards. Remote authentication is crucial for ensuring secure access to smart card-based systems. Their scheme offered robust security features, including mutual authentication and resistance against various attacks, enhancing the security of smart card systems [7].

Fouda, Fadlullah, and Kato (2011) proposed a lightweight message authentication scheme tailored for smart grid communications. Smart grids require efficient and secure communication protocols to support various applications. Their lightweight authentication scheme addressed these needs by providing efficient message authentication mechanisms suitable for smart grid environments [8].

In summary, recent research efforts have concentrated on developing robust authentication schemes tailored for specific domains such as smart grids, vehicular ad hoc networks, mobile social networks, and smart card systems. These schemes leverage cryptographic techniques, machine learning algorithms, and privacy-preserving mechanisms to enhance security, privacy, and efficiency in

communication systems. However, further research is needed to address emerging challenges and evolving threats in cybersecurity.

METHODOLOGY

Proposed Work:

The system proposed integrates both cryptography and machine learning techniques to bolster authentication and security within federated cloud services environments. It utilizes encryption algorithms for safeguarding data transmission and corresponding decryption algorithms for retrieving data, thereby ensuring the integrity and confidentiality of data. Furthermore, machine learning algorithms, specifically the ensemble Voting Classifier, are deployed for real-time threat detection and authentication enhancement. During authentication processes, entities undergo rigorous verification facilitated by machine learning algorithms, which scrutinize patterns and behaviors to identify and thwart unauthorized access attempts. Cryptographic principles are harnessed to secure data exchange, establishing a dependable framework for communication within federated cloud environments. The efficacy of the system is substantiated through performance evaluations using cybersecurity benchmarks and analysis tools, underscoring its superiority in terms of security features and communication efficiency vis-à-vis existing methodologies. Through the fusion of cryptography and machine learning, the proposed system offers a holistic solution to the challenges associated with secure data-sharing, thereby advancing cybersecurity in distributed computing environments.

System Architecture:

The proposed system architecture comprises three primary components: data transmission, encryption/decryption, and result analysis. Data transmission entails the exchange of information among various entities within federated cloud services. Encryption and decryption algorithms are employed to safeguard the data during transmission and retrieval, respectively. The encryption algorithm utilizes robust

cryptographic techniques to encode the data before transmission, whereas the decryption algorithm restores the received data to its original form. Result analysis entails assessing the system's effectiveness using performance metrics such as security features and communication efficiency.

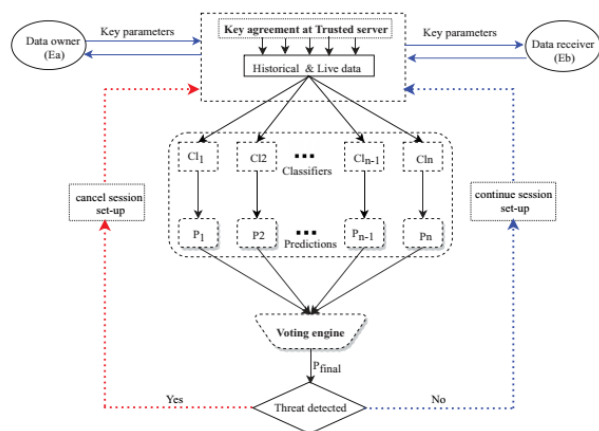

Fig 1 Proposed Architecture

Implementation:

A private key serves as the basis to randomly generate a sequence of pixels to store a secret message. This private key is also used to encrypt the message before embedding it into the pixels. To mitigate the effects of noise introduced during embedding, pictures with noise in each pixel are utilized. This approach is advantageous because the presence of noise in all pixels makes it challenging for hackers to identify those containing embedded information. A system is devised such that the image can only be viewed with the login credentials shared with the intended recipient. Instead of embedding each bit in all three components of a pixel (RGB), one component (either R, G, or B) is replaced with a byte containing the secret message byte. This method prevents hackers from determining the number of hidden bits in a pixel and the specific component where the message bits are stored.

Encryption Algorithm:

We have developed a web-based application to facilitate authorized user's communication and data transfer using images.

In the encryption interface, User 01 selects a cover image, inputs a key, and provides the data they intend to transfer. The data is then encrypted using a symmetric encryption algorithm like the Advanced Encryption Standard (AES). AES, known for its strong security and efficiency, processes data in blocks, typically 128 bits in size, and supports key sizes of 128, 192, or 256 bits. The user's provided key determines the encryption process, ensuring that only authorized parties possessing the correct key can decrypt the data.

Following encryption, the AES cipher is embedded into the chosen cover image using techniques like steganography. This method conceals the encrypted data within the image while preserving its visual appearance. This ensures data security during transmission, allowing only those with the corresponding decryption key to access the information.

Decryption Algorithm:

After embedding the data, the stego image appears undistorted and noise-free, closely resembling the cover image.

During decryption in our system, a corresponding algorithm is utilized to extract the embedded data from the stego image without introducing distortion or noise. This decryption process mirrors the embedding process, ensuring the recovery of the original data without altering the stego image's visual appearance.

For example, if steganography is employed to embed encrypted data into the cover image, the decryption algorithm first identifies and extracts the hidden data from the stego image. Once the encrypted data is retrieved, a symmetric decryption algorithm like AES is applied, using the same key as during encryption. This guarantees accurate decryption of the encrypted data while maintaining its integrity and confidentiality.

The decryption process operates efficiently, allowing authorized users with the correct decryption key to access the original data without any noticeable changes to the stego image. This method ensures secure and reliable data transfer within

federated cloud services environments, preserving the confidentiality and authenticity of the transmitted information.

CONCLUSION

In summary, our proposed system marks a significant leap forward in ensuring secure data exchange within federated cloud services environments. Through the integration of cryptography and machine learning techniques, our mutual authentication system delivers a robust response to authentication and security challenges. Employing encryption and decryption algorithms guarantees the

integrity and confidentiality of data, while machine learning algorithms, particularly the ensemble Voting Classifier, bolster real-time threat detection and authentication processes. A notable strength of our system is its capability to defend against a broad spectrum of security threats, encompassing user anonymity attacks, middle-man attacks, reflection attacks, replay attacks, denial-of-service attacks, and more. By refraining from directly disclosing users' true identities and frequently used session keys on public networks, our protocol erects a formidable barrier against potential breaches. Furthermore, the validation of our system's efficacy through performance evaluations using cybersecurity benchmarks and analysis tools underscores its superiority in security features and communication efficiency when compared to existing methodologies. Leveraging ProVerif security analysis further underscores the resilience of our mutual authentication technique against diverse security threats. In essence, our proposed system offers a holistic solution to the challenges of secure data-sharing in federated cloud services environments. Its fusion of cryptography and machine learning techniques not only enriches authentication processes but also drives advancements in cybersecurity within distributed computing environments.

FUTURE SCOPE

Looking ahead, there exists the opportunity to enhance our proposed system through the exploration of advancements in cryptography and machine learning techniques. Furthermore, integrating emerging technologies like blockchain could strengthen security and instill trust in data exchange processes. Additionally, expanding the application of our system to various domains beyond federated cloud services, such as Internet of Things (IoT) and edge computing, offers promising avenues for development. Continuous research and development endeavors can drive refinements and innovations to tackle evolving cybersecurity challenges and guarantee secure data exchange in ever more intricate and interconnected environments.

ABSTRACT

Every year, e-banking transactions that are blown up result in significant financial losses. Financial institutions must therefore enhance the fraud detection system and make the e-banking system more secure. Score rules and data-driven models are the primary subjects of research for fraud risk monitoring. The expertise that forms the basis of the score rule makes it susceptible to new fraud techniques. Usually used to address the imbalanced classification problem, data-driven models are built on machine learning classifiers. For e-banking transactions, we provide a novel fraud risk monitoring method in this study. For fraud detection, a model of score rules for both offline historical transactions and online real-time transactions is merged. The efficacy of our suggested system is demonstrated by experimental findings across a genuine huge dataset of electronic banking transactions. Our assessment helps us to pinpoint problems and research gaps that need to be taken into account for next projects.

INTRODUCTION

Fraud is the illegal use of deception with the goal of making money. Increased credit card transactions have resulted from a high reliance on internet technologies. The greatest benefit of cash for both online and offline transactions is that it is becoming more cordless. credit card misuse rate appears to be rising along with transaction rates. Credit card misuse can take two forms: external card fraud or unauthorized interior card access. While outer card fraud uses a stolen credit card to obtain cash through questionable means, inside card fraud happens when cardholders and banks consent to an error being committed under the false identity. The bulk of credit card frauds are the result of outside card fraud, which has been detected by numerous study developers. Big data has made manual approaches even more unfeasible because they require a lot of time and are ineffective when it comes to detecting fraudulent activities. Nonetheless, financial organizations have looked into new computational approaches to address the issue of credit card misuse.

The goal of crime detection is to prevent property or money from being acquired by unscrupulous individuals.. There are numerous avenues for obtaining criminality, as well as a wide range of industries and businesses. In order to create a cohesive overview of both credit-based online valid and non-valid payment data, increasing cause of detection approaches integrate several crime detection datasets. We can demonstrate how safely and anonymously we may credit the amount with the aid of the specified experimental outcome.. Additionally, it will function well and raise the security level. The actual transaction information, historical transaction trends, device identification, global latitude and longitude, IP address, geolocation, and BINl data must all be taken into account in this output. The output that was produced in this experimental setup was based on a customer problem, and the customers used analytically based replies that applied a set of business rules or analytical techniques using data from both internal and external sources.

EXISTING SYSTEM

The term "credit card fraud" refers to a broad category of scams that use a payment card, such as a credit card, as a tainted source of funding for transactions. Utilizing a credit card fraud detection technology, these illicit sources of transactions are located. Over the world, the volume of fraudulent transactions has increased dramatically. Phishing transactions made using credit cards that are carried out without the original cardholders' knowledge are known as fraud transactions. Payments for bills, private goods, internet purchases, and other activities have all been the subject of fraudulent activity. Therefore, credit card fraud is a significant problem these days that needs to be resolved right away. The machine learning approach is used to start the credit card fraud detection system.

The Synthetic Minority Oversampling Technique (SMOTE) algorithm and the Whale Optimization algorithm are the two primary algorithms utilized in machine learning. A class's dominance over another class in machine learning is resolved by the synthetic minority oversampling approach, or SMOTE.. We refer to this issue as class imbalance. When one class outnumbers the other classes in frequency, there is a class imbalance. Using SMOTE, the minority instances between the true instances are synthesized and differentiated. By reducing the minority examples from the true occurrences, the SMOTE () functions are employed. SMOTE () function parameters are used to synthesize instances. Based on a simulation of whale behavior, the whale optimization algorithm is suggested. Whale optimization is achieved through the way whales hunt, attack, encircle, and engage in other behaviors.

PROPOSED SYSTEM

The suggested system classifies the credit card data set using the random forest technique. A classification and regression algorithm is called Random Forest. Compared to a choice tree, irregular words have an advantage since they can modify the tendency to overfit to their own set of circumstances. In order to prepare each individual tree, a random subset of the preparation set is evaluated, resulting in the

selection of each node's component components from the whole list of capabilities at that moment. A choice tree is then built. On the other hand, because each tree is created independently of the others, it is extremely quick to prepare for massive information collections with plenty of highlights and information events in random forests.

SYSTEM SOFTWARE

Anacoda:

The goal of this free and open-source distribution is to make package management and deployment easier for scientific computing applications such as data science, machine learning, large-scale data processing, and predictive analytics. It supports both the Python and R programming languages.

Together with the virtual environment manager and over 1,500 items, the Anaconda distribution also includes the Anaconda package. In addition, Anaconda Navigator, a graphical user interface (GUI) to replace the Command Line Interface (CLI), is included. The management of package dependencies is the primary distinction between Anaconda and the pip package manager. This is a major issue for Python data science and the rationale behind Conda's existence. Regardless of whether they clash with other packages you've already installed, Pip installs all necessary Python package dependencies. Therefore, when you pip install a different package that requires a different version of the Numpy library, your working installation of, say, Google Tensor Flow, can suddenly cease working. More subtly, even though everything seems to be working, your data science may now yield different results, or you may not be able to replicate the same results elsewhere due to a different pip installation sequence.

When you provide version limits (e.g., you only require Tensor Flow ≥ 2.0), Anaconda examines everything you have installed, your current environment, and determines how to install compatible dependencies. Or it may inform you that your desired outcome is not achievable.

In contrast, Pip will install the desired package along with any dependencies, even if doing so breaks other packages. Using the conda install command, you can install individual open source packages from the Anaconda repository, Anaconda Cloud (anaconda.org), or your own private repository or mirror. All of the packages in the Anaconda repository are assembled and built by Anaconda Inc., which also offers binaries for Linux 64-bit, MacOS 64-bit, and Windows 32/64-bit. Additionally, you may use pip to install anything from PyPI into a Conda environment; Conda is aware of both pip's and its own installations. The desktop program Anaconda Navigator. Users may run apps and manage conda packages, environments, and channels without the need for command-line commands thanks to the Graphical User Interface (GUI) provided in the Anaconda distribution. In addition to installing

packages in an environment, Navigator may search for and find packages on Anaconda Cloud and in local Anaconda repositories. Windows, macOS, and Linux users can access.

Discussion

A program called Python was first created to make the implementation of numerical linear algebra operations simpler.. Since then, it has expanded into something considerably larger, and numerical algorithms are implemented for a variety of purposes. Although there are a few extensions, the core language is fairly close to ordinary linear algebra notation and may first cause some confusion for you..

With use Machine and Deep Learning we can increase the security level by monitoring the details of with greater limit and in addition to we also use Visual studio to continuous monitoring and easy identification of Fraudulent cases to rectify the public needs.

ABSTRACT

In this paper, we proposed a system to find the underground water without digging the bore well. The system is purely based on resistivity method. To exercise the resistivity method, field probes are used. A known value of current is passed to the probe which is fixed on the ground surface. Potential difference is noted across the field probes by using ohms law. If the reflected current from the ground is decreases when indicates the presence of water. This method is the condensation of several techniques. A 5v power supply is given to the microcontroller. The field probe draws current from the micro-controller. A gain factor is used for accurate calculation of resistance. Another one technique is data logging, which is used for easier access of the

data found from the ground surface. Also, it can be used for accessing the same data from remote

area. An ultrasonic sensor is used to find depth of the water from ground surface. Moreover, a GPS technology is used to have the exact

latitude and longitudinal position of the water. A buzzer is used, which is automatically rings,

if the water is found. All the obtained data are displayed using a LCD display. The data include the values of current, voltage, resistance, the GPS latitude, longitudinal

positions and even the depth. Thus this paper will meet the challenge of finding out ground water. This system is also a low-cost system can be made by using easily available materials.

LITERATURE REVIEW

The work is going to deploy Wenner method (Fig.1) to detect any underground water source. The Wenner array method is about keeping four electrodes collinear to each other. The four electrodes considered are D1,E1, D2, E2. D1 and D2 electrode will supply current externally at two ends. Between that two electrodes E1 and E2 electrodes are fixed which gives reading of voltage across soil. The distance between all four electrodes should be same. The readings are measured by voltmeter connected to electrodes E1 and E2. These readings are converted in resistance form by ohms law. This resistance is not proper resistance that of the soil. Soil is havi.

Motors connected with driver IC will turn on as you connect 9V dc battery with driver IC connection. Motors will remain in on mode for 3 seconds, as in programming it is done for 3seconds. So, robot will move ahead for 3 seconds. These are done for government level projects where large scale

investigations are carried out to ascertain the results of surface surveys .

Rod attached with servo motor will insert the electrodes attached with it inside the soil. Water witching is a traditional method adopted by people to detect bore-well locations. Using a forked stick to locate water source is known as water witched.

GPS location of that particular place where reading is taken is motor electrodes will be removed. Along with that GPS location of that particular place also displayed on serial monitor.

PROPOSED SYSTEM

In this system power supply is given to microcontroller and the other devices are activated. The fixed probe is taken reading from the surface and it send the data to controller. The check the resistivity of soil and then the output is displayed in LCD. The GPS is to find the location of the water flow. The buzzer is to indicate the water flow in surface. This system is fully based of resistivity of soil. Electrical resistivity method (Fig.2) is based on the difference in the electrical conductivity or the electrical

resistivity of different soils (Table-1). Resistivity is defined as resistance in ohms between the opposite phases of a unit cube of a material.

A geologic investigation begins with the collection, analysis, and hydrogeologic interpretation of existing topographic maps, aerial photographs, geologic maps and logs, and other pertinent records. This should be supplemented, when possible, by geologic field reconnaissance and by evaluation of available hydrologic data on stream flow and springs, well yields, groundwater recharge, discharge, and levels and water quality. In some places, the drainages may be fully controlled by the presence of minor and major structures like joints, faults and lineaments. Such 5 zones are good and potential zones for groundwater exploration.

MICROCONTROLLER

Arduino Uno board used in this project. The Arduino is a microcontroller board, based on the ATmega8/168/328, UNO R3 major in ATmega328. Arduino UNO R3 have 14 digital input/output pins (which include about 6 pins PWM output), 6 analog inputs and one 16MHz ceramic resonator, one USB connection and Power jack, an ICSP header (In Circuit Serial Programming) (like MAX232, RS232 programming) (Fig.4). Each of the 14 digital pins on the UNO R3 can be used as an input or output (they operate at 5 Volts and provide/receive a maximum of 40mA and has an internal pull-up resistor (disconnected by default) of 20-50 K ohms.), we can using functions as below:

LIQUID CRYSTAL DISPLAY

LCD (Liquid Crystal Display) screen is an electronic display module and find a wide range of applications. A 16×2 LCD display (Fig.5) is very basic module and is very commonly used in various devices and circuits. A 16×2 LCD means it can display 16 characters per line and there are 2 such lines. In this LCD each character is displayed in 5×7-pixel matrix. This LCD has two registers, namely, command and data

GPS

GPS stands for Global Positioning System (Fig.6) and was developed by the US Department of Defence as a worldwide navigation and positioning facility for both military and civilian use. It is a space-based radio-navigation system consisting of 24 satellites and ground support. GPS provides users with accurate information about their position and velocity, as well as the time, anywhere in the world and in all weather conditions.

ULTRASONIC SENSOR

The Arduino board sends a short pulse to trigger the detection, then listens for a pulse on the same pin using the Pulse In () function. The duration of this second pulse is equal to the time taken by the ultrasound to travel to the object and back to the sensor. Using the speed of sound, this time can be converted to distance.

BUZZER

A buzzer (Fig.8) designed to operate at 12 V can work perfectly at a voltage between 6 V and 28 V (see characteristics given by the manufacturer for not making stupidity). There are also buzzers that work directly on the AC mains 230 V. This type of buzzer is convenient to use, because unlike piezoelectric buzzers simple (simple piezoelectric transducers without associated electronics).

Table-1Resistivity&Aquifer characteristics

Thus, we have found the presence of ground water by using the resistivity method. The resistivity is varying for various aquifer characteristics such as clay/sand saturated with salt water, dry sand, fresh water and saline coastal area. The table above have a clear idea about the resistivity for various sand types.

For fresh water, the resistivity should be between 20-60. As water is good conductor of electricity, resistance decreases in soil and conductivity increases inside soil. So we can know from it that water is there inside soil at the depth electrodes are inserted inside soil. Voltage readings and GPS locations of place where soil testing was done was displayed on serial monitor screen.

Fig.9 Resistivity & aquifer characteristics

CONCLUSION

To identify the presence of groundwater from resistivity measurements, one can look to the absolute value of the ground resistivity, through the Archie law: for a practical range of fresh water resistivity of 20 to 60 ohm's, a usual target for aquifer resistivity can be between 50 and 2000 ohm. In this the groundwater is identified by the electrical method using the resistivity of the sand.

ABSTRACT

This paper describes the planning of a medication delivery stage using an autonomous drone. The framework uses SIMULINK to plan the robot regardless of obstacles, and the conveyance robot can find its way to the destination and fly there on its own with the help of a PC vision-based framework. The Direction Landing Framework was integrated into the framework to assist the robot's administrator or independent framework in selecting the best arrival plots for landing; the arrival determination was based on the heading and power of the light. It transports the conveyance bundle from the home area to the client area via the developed method. A test system is then modified and used as a pre-mission instrument to predict mission outcome and after approval. To fulfil its conveyance purpose, a competent payload structure is designed and created for the quadcopter. Once the robot is gathered with the payload device, SolidWorks is used to establish its true perimeter. Comparable limits, such as execution coefficients, are then updated in the quadcopter characteristics of the test system. The quadcopter and simulator have been tested in the autonomous delivery mission in order to compare outcomes and demonstrate how physical aspects such as weather and speed affect them.

INTRODUCTION

A Quadcopter is a rotor-based, automated elevated vehicle. Quadcopters mobility and track down applications in different fields. The elements of a quadcopter is profoundly non-direct. Besides, it is an under-activated framework with six levels of opportunity and four control inputs. The push as well as the forces expected for shifting the quadcopter are the control inputs which decide the movement of the vehicle. The push as well as forces are produced by changing the rotor speeds. The rotor blades always produce thrust in the same direction as the quadcopter's center. Thusly, to accomplish impetus in a specific heading, the pivot of quadcopter ought to be shifted concerning the vertical. The translational movement of a quadcopter is thus combined with its rakish direction, making quadcopter elements and control exceptionally mind boggling. The deficiency of quadcopter propeller cutting edges can cause the quadcopter to crash. Aside from the financial loses related with the harm to quadcopter parts, it can have many adverse results. Loss of a quadcopter utilized for surveillance work can prompt loss of significant military insight and causes its gamble being found by the foe. In movie film making, warm imaging photography and so on., the hardware mounted on the quadcopter are exorbitant and propeller disappointment can prompt the harm of significant gear. In search and salvage activities in misfortune impacted districts, the disappointment of the quadcopter can prompt potential postponements, expanding the endanger on the existence of impacted individuals. In material taking care of frameworks, disappointment might prompt harm of exorbitant parts. Added to this, there is likewise the gamble of the quadcopter crashing on to individuals and causing wounds particularly in broad daylight spaces. Unmanned Aerial Vehicles (UAVs), commonly known as drones, have emerged as versatile platforms with applications spanning various industries, including logistics and healthcare. The integration of UAVs into the healthcare sector presents a groundbreaking opportunity to revolutionize medical supply chain logistics. This project focuses on the design and

simulation of a UAV drone system for the efficient and timely delivery of medical kits using MATLAB Simulink. The healthcare industry faces challenges related to timely access to critical medical supplies, especially in remote or disaster-stricken areas. Traditional delivery methods often struggle to overcome geographical constraints and time-sensitive demands. The use of UAVs for medical kit delivery offers a solution to these challenges by providing rapid and reliable transportation. This project aims to employ Simulink, a powerful simulation tool, to model and analyze the dynamics of a UAV drone system tailored for medical kit delivery. Simulink provides a platform for comprehensive modeling, simulation, and testing of complex systems, allowing for a detailed examination of the drone's performance under various conditions.

The UAV drone designed in this project will be equipped with a secure and temperature-controlled compartment to ensure the integrity of medical supplies during transportation. The system will be optimized for efficient route planning, obstacle avoidance, and real-time monitoring, all crucial aspects for a successful medical kit delivery mission. Furthermore, the project will explore the integration of communication technologies, such as GPS and wireless data transmission, to enable seamless tracking of the UAV and facilitate communication between the drone and ground control. This connectivity ensures precise navigation, enhances safety, and allows for immediate response to any unforeseen circumstances. The simulation results obtained through Simulink will provide insights into the performance metrics of the UAV drone system, including delivery time, energy consumption, and reliability. This information will be instrumental in refining the design and optimizing the operational parameters to meet the specific requirements of medical kit delivery.

In summary, the integration of UAV technology into medical kit delivery systems holds immense potential for transforming healthcare logistics. This project, utilizing Simulink, aims to design and simulate a UAV drone system that not only addresses

the challenges associated with medical supply chain logistics but also sets the stage for a more resilient and responsive healthcare infrastructure.

COORDINATE FRAMEWORK

Dynamics Model:

Begin by modelling the UAV drone dynamics. Use Simulink blocks for six-degree-of-freedom (6DOF) to represent the drone's motion. Define parameters such as mass, inertia, and aerodynamic coefficients based on your drone specifications.

Control System:

Develop a control system to stabilize and control the UAV's movement. You can use PID controllers or other control algorithms depending on your requirements. Connect the control system to the dynamics model to create a closed-loop control system.

Navigation and Waypoints:

Implement a waypoint navigation system using Simulink blocks. Define waypoints that represent the desired path for the drone. Integrate a path-following algorithm to guide the drone along the defined waypoints.

Package Release Mechanism:

Design a mechanism to simulate the release of the medikit package. Use logical blocks or triggers in the control logic to initiate the release action at a specific location.

Communication System:

Model a communication system to receive commands and send telemetry data. Utilize Simulink blocks to represent communication components. Consider incorporating error handling mechanisms for robust communication.

Obstacle Avoidance:

Integrate obstacle detection and avoidance mechanisms into your model. Use Simulink blocks to simulate the drone's response to obstacles and implement collision avoidance logic.

Simulation Configuration:

Set up simulation parameters such as the simulation time, solver settings, and other relevant configurations. Ensure that the simulation environment reflects real-world conditions for testing and validation.

Visualization:

Use Simulink 3D Animation blocks to visualize the drone's movement and the medikit package delivery process. Incorporate appropriate visualization elements to monitor the drone's behaviour during the simulation. Remember, this guide is meant to help you structure your Simulink model. Be creative in implementing your specific drone characteristics, control algorithms, and delivery scenarios. This approach will ensure that your model is unique and tailored to your project requirements.

The flying sidekick traveling salesman problem: Optimization of drone assisted parcel delivery

In the main led examinations toward this path resolved two issues connected with drone-based conveyance related to trucks to limit the outing time for both the robot and the truck while getting back to the stop. The first problem that was dealt with was the flying sidekick traveling salesman problem, which was solved using a mixed integer linear programming (MILP) formulation to reduce the expected delivery time

by assigning the drone to the truck to deliver packages to customers. With respect to issue, the creators proposed a heuristic methodology called "Truck First, Robot Second", where the truck way is intended to determine the mobile sales rep issue. The truck goes along a course that starts at a terminal, serves clients an route, then, at that point, wraps up at the terminal. The subsequent issue handled was the mobile sales rep issue with equal robot planning. Rather than the primary issue, this issue thinks about that the robot and the truck perform conveyances freely. The heuristic approach proposed for this issue accepts that the robots will serve all the clients inside their most extreme reach, while the truck will serve the excess clients. In contrast, a number of assumptions.

were later made to simplify the model, including the authors' assumption that the number of drones is very small, that a drone's flight velocity and duration are constant, that the drone preparation is done by a person in the vehicle (rather than by the drone), and that the depot is close to all customers' centers. In any case, the conveyance issue is viewed as a stochastic issue and involves a huge armada of completely independent robots in the conveyance framework, in this way making the demonstrating exceptionally testing.

accompanying headings: (1) vehicle directing issue with drones; (2) the issue of the assigned drone; 3) the charging procedure and the location of the charging station; 4) armada dimensioning. While considering the Vehicle Directing Issue with Robots (VRPD), a large portion of the writing has tended to half and half conveyance frameworks, which join two conveyance modes: the vehicle-based conveyance framework and the robot-based conveyance mode. Most issues with last-mile conveyance with drones recommend that the ethereal vehicle is shipped close to the objective of the bundle by ground vehicles. From here, while the robot is conveying a bundle, the van can serve different clients who are not reachable by drone. Thus, the robot will actually want to keep serving all clients who are inside its flight zone, expanding ease of use and making the timetable more Adaptable.

bundle. The authors assumed that the operator only deploys one depot (charging station) in the area and that the operator has sufficient fully charged batteries to meet the drone's energy needs before deliveries could begin. Interestingly, it would be extremely difficult and pensive for a conveyance organization to send numerous stops and battery trading stations, as well as to oversee battery trading between trips.

The proposed drone-vehicle conveyance way could build the normal conveyance time contrasted with the robot direct conveyance mode. Moreover, the

correspondence innovation of robots to vehicles, which permits the robot to gather vehicle trip data, is still in the beginning phases of purpose in the operations business. It proposed a blended whole number programming (MIP) model to address the unique pickup and conveyance issue, accepting that the conveyance framework is supported by charging stops for trading batteries when the robot's battery is practically depleted. Additionally added to the writing on the re-energizing station sending issue. The creators talked about drone dinner conveyance issues for cafés, where an organization of charging stations is proposed to help robots' restricted flight range. A heuristic optimization model was proposed to determine the best location and number of recharging stations to maximize coverage under a set of constraints.

RESULTS

The three unique regulators utilized for the demeanor control; a stage input is offered as the ideal benefit for every one of the disposition factors. Parameters like rise/fall time and percentage overshoot/undershoot are used in the comparison. Taking a gander at the step reaction for, it is obvious that LQR regulator shows the best execution as the fall time is least and there is no huge undershoot. The mix of FBL and PD regulator shows a nearly slower reaction with some undershoot. PID regulator shows relatively terrible showing as the fall is exceptionally steady and it requires a long investment to settle, however without any motions. All the three regulators arrive at the consistent state esteem without any motions, thus settling time isn't viewed as here to convey the bundle.

ABSTRACT

Intracranial haemorrhage (ICH) poses a large chance to affected person fitness, regularly modern requiring set off diagnosis and intervention. In latest years, medical imaging techniques, specifically computed tomography (CT) scanning, have end up critical tools for detecting and characterizing ICH. This paper offers a complete evaluate comprehensive review of the state-of-the-art techniques for the segmentation, category, and visualization cutting-edge intracranial haemorrhage in CT mind pics. The evaluate encompasses numerous methodologies, consisting of conventional picture processing strategies, system cutting-edge algorithms, and deep brand new strategies, highlighting their strengths, limitations, and capability applications in scientific exercise. Additionally, it discusses the challenges associated with correct ICH detection and quantification, inclusive of the presence modern day artifacts, anatomical variations, and sophistication imbalance. Furthermore, the paper explores emerging tendencies in ICH research, which includes the combination trendy multimodal imaging information and the improvement trendy interactive visualization gear for enhanced medical choice-making. The segmented portion from each CT image is constructed into a single 3D volumetric structure and essential information such as region Area, volume and location are provided. Further the classification accuracy between normal brain and ICH brain is 95.8%. Such a 3D visualization, Classification and volumetric analysis of ICH can provide the exact

and necessary information to the neurologist which is essential for the treatment of ICH.

INTRODUCTION

Intracranial haemorrhage (ICH) represents a critical medical condition characterized by bleeding inside the cranium. It encompasses various types, which includes epidural, subdural, subarachnoid, and intracerebral haemorrhages, each imparting unique challenges in prognosis and control. ICH can end result from diverse etiologies, consisting of trauma, vascular abnormalities, high blood pressure, coagulopathies, or underlying structural lesions. No matter the underlying reason, prompt identification and precise localization of ICH are paramount for initiating timely interventions and improving affected person consequences.

Medical imaging performs a pivotal function in the detection and characterization of intracranial haemorrhage. Among the modalities to be had, Computed Tomography (CT) imaging sticks out as a cornerstone in the diagnostic workflow for brain-associated pathologies. CT offers numerous blessings over other imaging modalities, which includes rapid acquisition instances, high spatial decision, and the capability to visualize each bony structures and smooth tissues with incredible assessment decision. This makes CT especially properly-suitable for assessing acute haemorrhagic activities in the mind, allowing clinicians to swiftly compare the extent and severity of bleeding.

The importance of early detection and correct analysis of ICH cannot be overstated. Behind schedule or overlooked prognosis may lead to devastating outcomes, including neurological deficits, everlasting disability, or maybe demise.

Consequently, developing dependable and efficient methods for the segmentation, category, and visualization of intracranial haemorrhage in CT brain snap shots is of extreme importance.

Early detection of ICH is crucial for starting up timely interventions, inclusive of surgical evacuation of hematomas or management of anticoagulant reversal dealers that could substantially enhance affected person consequences and reduce mortality charges. Moreover, correct localization and characterization of haemorrhagic lesions are essential for guiding remedy decisions and assessing analysis. As an example, distinguishing among exceptional styles of ICH (e.g., disturbing vs. Spontaneous, or intra parenchymal vs. Subdural) is crucial, as their management strategies can also differ drastically.

Fig 1.1 Intracranial haemorrhage CT brain image

Intracranial haemorrhage is defined as bleeding within the skull, as demonstrated in Figure 1.1.

Intracranial haemorrhage is an important cause of death and disability and is a subtype of stroke. Intracranial haemorrhage can occur spontaneously or in the setting of trauma. Spontaneous intracranial haemorrhage can be associated with a variety of disease processes including, but not limited to, arteriovenous malformations, ruptured aneurysms, anticoagulation, tumors, venous sinus thrombosis, hypertension, cerebral amyloid angiopathy, and haemorrhagic

conversion of is chemic stroke. Traumatic intracranial haemorrhage can occur in anyone who has suffered trauma, but patients on anticoagulation are at a substantially increased risk of intracranial haemorrhage. Intracranial haemorrhage is an emergency with rapid diagnosis critically important to improve patient outcomes as patients often deteriorate rapidly within the first few hours of the onset of symptoms.

BACKGROUND AND RELATED WORK

Intracranial haemorrhage (ICH) is a complex and doubtlessly life-threatening situation that requires fast and correct diagnosis for suitable scientific control. Over the years, researchers and clinicians have explored various methods to automate the detection, segmentation, and type of ICH lesions the use of medical imaging strategies, specifically computed tomography (CT) imaging.

PREVIOUS STUDIES ON ICH DETECTION, SEGMENTATION, AND CATEGORY

Early tries at automatic ICH detection relied closely on traditional picture processing strategies, together with thresholding, edge detection, and morphological operations. At the same time as those techniques supplied a foundation for automatic evaluation, they regularly struggled with as it should be segmenting haemorrhagic lesions, mainly inside the presence of noise, artifacts, and anatomical versions.

In current years, there was a paradigm shift in the direction of machine studying (ML) and deep gaining knowledge of (DL) methods for ICH detection and evaluation. ML algorithms, which includes aid vector machines (SVM), random forests, and gradient boosting machines (GBM), had been employed to examine discriminative functions from handmade descriptors and radiomic features extracted from CT pix. Even as those methods have shown promising consequences, they frequently depend on predefined characteristic sets and might conflict with capturing the complex spatial relationships inside ICH lesions.

Deep mastering techniques, specifically convolutional neural networks (cnns), have emerged as effective gear for computerized clinical picture analysis, together with ICH detection and segmentation. CNN architectures, which includes U-net, completely Convolutional Networks (fcns), and deeplab, have validated top notch skills in learning hierarchical features without delay from raw image information, enabling accurate and robust segmentation of haemorrhagic lesions. These DL-primarily based processes have proven superior overall performance as compared to conventional strategies, mainly in challenging eventualities with heterogeneous lesion traits and variable imaging protocols.

EXISTING METHODS AND THEIR BARRIERS

Despite the good sized development in automated ICH detection and analysis, several limitations persist. One commonplace challenge is the lack of massive-scale annotated datasets for schooling and validating system mastering fashions. Even as efforts were made to create publicly to be had datasets, which includes the RSNA Intracranial Haemorrhage Detection assignment dataset, those datasets may not completely capture the range of clinical eventualities encountered in real-world practice.

Every other hassle is the generalizability of present algorithms throughout exclusive imaging modalities, acquisition protocols, and patient populations. Many algorithms are skilled and evaluated on datasets from precise establishments or imaging protocols, which may additionally limit their applicability to other settings. Moreover, the interpretability of deep studying fashions stays a task, as those fashions often function as "black containers," making it difficult to apprehend the underlying choice-making method.

ADVANCES IN CLINICAL IMAGING GENERATION AND COMPUTATIONAL STRATEGIES:

Latest advances in clinical imaging generation have contributed to advanced detection and characterization of intracranial haemorrhage. Improvements in CT scanner hardware, inclusive of twin-power CT and iterative reconstruction strategies, have led to enhancements in picture high-quality, assessment decision, and artifact discount. Those improvements have facilitated the visualization of diffused haemorrhagic lesions and stepped forward the accuracy of automated detection algorithms.

At the computational the front, trends in deep gaining knowledge of architectures and education methodologies have improved development in automated ICH detection and segmentation. Switch mastering strategies, together with excellent-tuning pretrained fashions on area-specific information, have enabled speedy improvement of high-performance models with constrained annotated information. Moreover, the integration of multimodal imaging information, along with CT perfusion, diffusion-weighted imaging (DWI), and magnetic resonance imaging (MRI), holds promise for enhancing the sensitivity and specificity of automatic ICH detection algorithms.

LITERATURE REVIEW

Danfeng Guo et al (2020) proposed that total of 1176 head CT scans were collected from the hospitals, with 581 ICH patients and 595 normal subjects. Each slice in these head CT images has a size of 512_512 pixels. Divided the dataset into a random sample of 706 subjects for training, 235 for validation and 235 for testing, 3D/2D resnet18 and 3D U- Net were used as subject-level/slice-level classification task and segmentation task baseline models, respectively. Additionally performed ablation experiments by evaluating the performance of: ichnet for the classification tasks only without the segmentation branch (ichnetcls), ichnet for the segmentation task only without classification branch (ichnetseg), ichnet without attention blocks. They used

five metrics (accuracy, sensitivity, specificity, F1 score, and area under the curve (AUC)) to evaluate models' performance for the classification tasks, and used dice coefficient as the evaluation metric for the segmentation task. Multi-task ichnet generally outperforms the baseline models (3D/2D resnet18 for classification and 3D U-Net for seg) as well as single-task ichnet models (ichnetcls and ichnetseg) across all metrics. It should be also noted that the single-task ichnet model's performance is still notably better than the corresponding baseline model, indicating that convlstm module can be a more efficacious approach in capturing sequential information than directly utilizing 3D convolution. For the seg task, the use of attentionmechanism also brings additional performance improvement but not as substantial as adding the class branch.

Kai Hu et al (2020) developed that Intracranial haemorrhage, as a common disease of brain injury, is a serious threat to human life and health. Accurate segmentation of ICH regions will greatly help doctors in formulating treatment plans for their patients. To address this problem, in this paper they propose a novel ICH region segmentation

Method using deep neural networks, To extract the multi-scale features of ICH regions, propose a novel end-to-end network architecture, named ED-Net, which contains an encoder part and a decoder part. The encoder can effectively extract both the high- and low-level semantic features, and the decoder can integrate the multi-scale features to form a unified feature representation of ICH regions. Due to the existing difficulty in the segmentation of small ICH regions, they propose a new synthetic loss function to consider more local details and small regions of ICH. Because the new loss function considers the different rois in the image, it can also effectively overcome the problem of data imbalance. To use a total of 480 cases from four hospitals to verify the effectiveness of the proposed method. Also compare this method with nine state-of-the-art semantic segmentation approaches including segnet, U-Net, deeplabv3, pspnet, X-Net, CLCI-Net, Dual fcns, patchfcn and

multiresunet. The experimental results show that encoder decoder model outperforms other methods and achieves the best segmentation results. The results on the multi-center clinical data also indicate that our model is an effective method for ICH region segmentation and may be applied to other clinical medical image segmentation tasks in the future.

Pankaj Singh et al (2018) developed that a Diagnosis of haemorrhage is major task for the physicians because of vital mortality rate. This paper proposed a method for segmentation of intracranial haemorrhage on CT images. In this proposed method tried to improve the accuracy of haemorrhage diagnosis, which can save lives of patients. To achieve this object a hybrid method of FCM and MDRLSE is used for the segmentation of intracranial haemorrhage. FCM clustering is used for initialization of level set function in MDRLSE. Experimental results of ICH segmentation show that proposed hybrid method is much accurate for the segmentation of haemorrhagic regions. The results of ICH segmentation cooperate well with the experts measurements. Doctors in clinical can use this proposed method for the diagnosis of haemorrhage.

Sumijan et al (2017) proposed this research provides a method for segmentation, extraction and 3D reconstruction image of the incision. Merger Otsu method, feature region and Morphological can generate several things including: Algorithm cropping elliptical proposed models can accurately separate area of the skull and the brain from other areas in the image of a CT scan. These results greatly facilitate and accelerate the process of extraction of haemorrhage in the brain area. Combined Otsu method, the search and removal of objects as well as the area of mathematical morphology is very effective in segmenting and extracting areas of bleeding in the brain. Otsu algorithm is used to detect and Segmentation areas of brain haemorrhage and other areas that have a high intensity value. Search algorithm is developed to determine the position and area of each white area of Otsu algorithm results. Removal algorithm is used to identify and eliminate areas that are not part of the

area Haemorrhage, so what is left is only the bleeding area. Mathematical morphology algorithm used to cover parts of the bleeding area lost by previous processes. The area and volume calculation algorithm can calculate the area of a cerebral haemorrhage per slice and the volume of the entire slice through 3D reconstruction bleeding area. 3D reconstruction algorithm used brain haemorrhage area is referring to the algorithm linear interpolation between two adjacent slices.

Ameli et al (2017) proposed a Haemorrhage is seen from the image of the head scan, furthermore the image segmentation of head using the otsu method. Otsu method is one of thresholding method. The purpose of the method is to divide the gray level graphic histogram into two different regions automatically without requiring the user's help to enter the threshold value Segmentation processes are performed using the matlab programe and the image used for segmentation is a CT scan image. CT head image with haemorrhage on slice 26 until slice 37 before segmentation. The result of segmentation of otsu method can separate object with its background, that is brain haemorrhageand brain. The next step is followed by morphological operations to improve the segmentation results and eliminate the noise and eliminate the undesirable area. The

Result of segmentation with otsu method and morphological operation is binary image. The binary image is used for calculating the area of haemorrhage in the brain by summing all white objects with pixels of value is 1. The total area value obtained is still in pixel units, so as to convert it into mm² units, then the result is divided by image spatial resolution is 2,7380 pixels/mm. The head image in brain haemorrhage can be well segmented, and to know the region and area of haemorrhage segmented can be seenfrom the visualization of the segmentation. Conclude that the use of otsu method and morphological operation for image segmentation process can be well implemented.

DATA ACQUISITION AND PREPROCESSING

Description of the Dataset:

Our look at leveraged a complete dataset inclusive of CT brain photographs amassed from more than one scientific establishments and research repositories. The dataset turned into meticulously curated to encompass a diverse array of instances, making sure a broad representation of intracranial haemorrhage (ICH) eventualities. The inclusion standards encompassed sufferers with each acute and continual ICH, in addition to various tiers of haemorrhage severity, place, and etiology.

Each CT scan inside the dataset changed into followed through distinctive clinical metadata, such as patient demographics (age, gender), applicable clinical history (e.g., presence of hypertension, anticoagulant use), and pertinent imaging findings (e.g., haemorrhage area, quantity). Furthermore, to facilitate algorithm improvement and assessment, the dataset changed into partitioned into distinct subsets for schooling, validation, and testing, with careful attention given to preserving a balanced distribution of fantastic and negative instances throughout the subsets.

Floor truth annotations for haemorrhagic areas within the CT snap shots were meticulously delineated by using board-certified radiologists or neuroimaging specialists. Those annotations have been meticulously reviewed and established to make sure accuracy and consistency across the dataset. Special interest was paid to appropriately shooting the quantity and barriers of haemorrhagic lesions, accounting for variations in lesion morphology, size, and imaging characteristics.

Stringent measures have been undertaken to make sure affected person privacy and compliance with moral hints governing the usage of medical imaging data in studies. All affected person identifiers have been anonymized, and institutional evaluation board (IRB) approval changed into received in which relevant.

Preprocessing Steps:

2D sliced CT Intracranial haemorrhage image in RGB format. Image resizing is necessary to process a image and fix unique size of (256x256). Further the resized

RGB image can be converted in to Gray scale image for performing image processing. Grayscale image in 8-bit representation will be a matrix, and the values can be anything from 0 to 255. 0 indicates black pixels and 255 indicate white pixels and in between different shades from black to white will come.

Image shown in Fig 4.1(a) can be resize in to (256x256). Resized image in RGB can be converted in to gray scale image shown in fig 4.1(b).

Fig 4.1 Pre-processed CT Intracranial haemorrhage

Prior to undertaking picture evaluation obligations, a series of preprocessing steps have been employed to standardize and decorate the excellent of the CT brain photographs:

Noise reduction: CT pix are inherently susceptible to noise bobbing up from various sources, consisting of digital noise, affected person movement artifacts, and photon scatter. To mitigate these assets of noise, advanced denoising algorithms, including iterative reconstruction strategies or adaptive filtering techniques, were carried out to the uncooked CT pics. Those algorithms effectively suppressed noise whilst keeping crucial photograph features and information.

Cranium Stripping: The presence of extracranial systems, which include the cranium and soft tissues, can introduce confounding factors in automatic image analysis duties. To deal with this, robust cranium stripping algorithms have been employed to section the intracranial region from the encircling non-brain tissues.

Those algorithms applied superior morphological operations, depth thresholding, and location developing strategies to as it should be delineate the brain parenchyma at the same time as with the exception of extraneous structures.

Depth Normalization: CT pix acquired from exclusive scanners or imaging protocols may exhibit variations in intensity values, main to inconsistencies in picture look and contrast. To standardize the intensity traits throughout the dataset, intensity normalization techniques had been carried out. This worried rescaling the depth values to a commonplace range or employing histogram equalization strategies to align the depth distributions of the pictures.

Spatial Resampling: CT images frequently show off variations in voxel dimensions and orientations, that could impact the performance of subsequent picture evaluation algorithms. To make sure uniformity in voxel spacing and alignment across the dataset, spatial resampling techniques have been applied.

This concerned interpolating the photo voxels to reap isotropic voxel dimensions and constant orientation along the x, y, and z axes.

By using carefully imposing these preprocessing steps, we aimed to optimize the CT pix for next analysis, ensuring strong and reproducible effects in computerized ICH detection, segmentation, and characterization responsibilities. Furthermore, those preprocessing measures have been vital for minimizing artifacts, enhancing image quality, and facilitating the development of clinically relevant picture analysis algorithms.

SEGMENTATION OF INTRACRANIAL HAEMORRHAGE

Different Segmentation Techniques Employed

Traditional Methods:

Traditional segmentation approaches for intracranial haemorrhage often rely on classical image processing techniques. These methods typically involve thresholding, where pixels or voxels with intensity values above a certain threshold are classified as haemorrhagic, and those below are classified as non-haemorrhagic.

Region growing algorithms iteratively expand regions based on predefined criteria, such as intensity similarity or spatial connectivity. Additionally, morphological operations, such as erosion and dilation, are employed to refine the segmented regions and remove artifacts.

The Pre processed image can be cluster by using K-means cluster. The clustered image shown in Fig 5.1.

Fig 5.3 ICH present clustered region

Main aim is to segment a ICH region from the image. In Fig 5.4 image shows both ICH as well as Skull components. Need to remove the Skull region for efficient segmentation by using connected components. Skull region identify by using thresholding method.

Machine Learning (ML) Approaches:

Machine learning-based segmentation techniques leverage statistical learning algorithms to automatically identify and delineate intracranial haemorrhage regions within CT images. Supervised ML methods, such as support vector machines (SVM) and random forests, learn discriminative features from annotated training data to classify pixels or voxels as belonging to haemorrhagic or non-haemorrhagic regions. Unsupervised ML techniques, such as k-means clustering, partition the image into clusters based on feature similarity, with haemorrhagic regions emerging as distinct clusters.

Deep Learning (DL) Techniques:

Deep learning-based segmentation methods have emerged as state-of-the-art approaches for segmenting intracranial haemorrhage from CT images. Convolutional neural networks (CNNs) are particularly well-suited for this task due to their ability to learn hierarchical features directly from raw image data. Architectures like U-Net, Fully Convolutional Networks (FCNs), and Deep Lab employ encoder-decoder structures to capture contextual information and generate pixel-wise segmentation masks. DL-based approaches offer superior performance

compared to traditional methods, as they can handle complex lesion morphologies and variations in imaging characteristics.

Evaluation Metrics Used for Assessing Segmentation Accuracy:

Dice Similarity Coefficient (DSC):

The DSC measures the spatial overlap between the predicted and ground truth segmentation masks. It is calculated as twice the intersection of the predicted and ground truth masks divided by the sum of their sizes. A DSC value of 1 indicates perfect overlap, while lower values indicate poorer segmentation accuracy.

Jaccard Index (JI) or Intersection over Union (IoU):

The Jaccard Index (also known as IoU) measures the overlap between the predicted and ground truth segmentation masks, normalized by their union. It is calculated as the intersection of the predicted and ground truth masks divided by the union of the two masks. Similar to DSC, higher values indicate better segmentation performance.

Sensitivity and Specificity:

Sensitivity (true positive rate) measures the proportion of true haemorrhagic pixels or voxels correctly identified by the segmentation algorithm, while specificity (true negative rate) measures the proportion of true non-haemorrhagic pixels or voxels correctly identified. These metrics provide insights into the algorithm's ability to detect both positive and negative instances.

Accuracy and Precision:

Accuracy measures the overall correctness of the segmentation results, while precision measures the proportion of true positive predictions among all positive predictions. These metrics offer a comprehensive assessment of segmentation performance, considering both true positive and true negative instances.

Harsdorf Distance:

Harsdorf distance quantifies the maximum distance between corresponding points in the predicted and ground truth segmentation masks. It provides a measure

of spatial discrepancy between the two masks, with lower values indicating better alignment and agreement. Hausdorff distance is particularly useful for evaluating the spatial accuracy of segmentation algorithm.

By utilizing these evaluation metrics, researchers can quantitatively assess the performance of segmentation algorithms and compare their accuracy and robustness across different methodologies and datasets. Additionally, these metrics provide valuable insights into the strengths and limitations of segmentation algorithms, guiding further improvements and refinements in automated ICH detection and analysis.

CLASSIFICATION OF INTRACRANIAL HAEMORRHAGE

Classification Algorithms:

Support Vector Machine (SVM): SVM is a supervised learning algorithm that is effective for classification tasks, particularly in high-dimensional spaces. It works by finding the hyperplane that best separates different classes while maximizing the margin between them. SVMs can handle linear and non-linear classification problems using different kernel functions.

Fig 6.1 Linear SVM classifier

The goal of the SVM algorithm is to create the best line or decision boundary that can segregate n- dimensional space into classes so that easily put the new data point in the correct category in the future. The best decision boundary is called a hyperplane shown in fig 6.1.

Random Forest: Random Forest is an ensemble learning method that builds multiple decision trees during training. Each tree is trained on a random subset of the data and selects a random subset of features for splitting at each node. The final classification is determined by aggregating the predictions of individual trees, often through voting or averaging.

Convolutional Neural Network (CNN): CNNs are deep learning models specifically designed for processing structured grid-like data, such as images. They consist of convolutional layers that learn hierarchical representations of features directly from the input images. Pooling layers are used to reduce spatial dimensions, and fully connected layers at the end perform the final classification based on the learned features.

Feature Extraction Methods and Feature Selection Techniques:

Handcrafted Features: Traditional feature extraction methods involve manually defining and computing specific features from the images, such as texture, intensity, or shape features. These features are often designed to capture relevant information related to the underlying characteristics of intracranial haemorrhage.

Deep Learning-based Features: With CNNs, features are learned automatically from the raw pixel values of the images. Convolutional layers extract hierarchical representations of features, starting from simple patterns (e.g., edges) to more complex and abstract features (e.g., shapes, textures). These learned features are highly informative for classification tasks and often outperform handcrafted features.

Feature Selection: Feature selection techniques aim to identify the most informative features and reduce the dimensionality of the feature space. Methods such as principal component analysis (PCA), recursive feature elimination (RFE), or feature importance ranking from ensemble methods like Random Forest can be employed to select the most discriminative features.

Performance Evaluation Metrics for Classification Accuracy

Accuracy: Accuracy measures the proportion of correctly classified samples out of the total number of samples. It provides an overall assessment of the classifier's performance.

Precision and Recall: Precision measures the proportion of true positive samples among all samples classified as positive, while recall (also known as sensitivity) measures the proportion of true positive samples that were correctly identified. These metrics are particularly useful when dealing with imbalanced datasets.

Specificity: Specificity measures the proportion of true negative samples that were correctly identified. It is especially important in medical applications to ensure that healthy cases are not misclassified as diseased.

F1 Score: The F1 score is the harmonic mean of precision and recall, providing a balanced measure of the classifier's performance, especially in situations where precision and recall have contrasting values.

Receiver Operating Characteristic (ROC) Curve and Area under the Curve (AUC): ROC curves visualize the trade-off between sensitivity and specificity across different threshold values. AUC quantifies the classifier's ability to distinguish between classes, with higher values indicating better performance.

Confusion Matrix: A confusion matrix summarizes the performance of a classification algorithm by tabulating the true positive, false positive, true negative, and false negative predictions. It provides insights into the types of errors made by the classifier.

These performance evaluation metrics provide a comprehensive understanding of the classification model's effectiveness in distinguishing between different classes of intracranial haemorrhage. By analysing these metrics, researchers and clinicians can assess the strengths and weaknesses of the classification methods and make informed decisions about their applicability in clinical practice.

VISUALIZATION TECHNIQUES

2D Visualization Techniques:

Overlay Maps: Overlaying color-coded maps onto the original CT images allows for a straightforward visualization of haemorrhage regions. Different colors may represent different types or severity of haemorrhage.

Heatmaps: Heatmaps utilize color gradients to indicate the intensity or probability of haemorrhage at each pixel. This method provides a visual representation of the distribution and extent of haemorrhage within the brain.

Contour Plots: Drawing contours around haemorrhage regions helps delineate their boundaries, aiding in precise localization and measurement of haemorrhage volume.

Slice-by-Slice Visualization: Viewing individual CT slices with annotated haemorrhage regions enables detailed examination of haemorrhage morphology and its relationship with surrounding structures.

3D Visualization Techniques:

Surface Rendering: Generating 3D surface models of the skull and brain, with haemorrhage regions highlighted, provides an intuitive spatial understanding of haemorrhage location and extent.

Volume Rendering: Rendering the entire CT volume with different opacity levels assigned to haemorrhage regions allows for a transparent visualization of surrounding tissues, facilitating the assessment of haemorrhage location in relation to adjacent anatomical structures.

Concatenated or Reconstructed image can be visualized in 3D image using Iso surface shown in fig. 7.1

(a) Iso surface 3D visualization (b) Faces and Vertices Representation

Fig 7.1: 3D visualization using Iso surface

Is surface Extraction: Identifying and rendering surfaces within the CT volume that represent haemorrhage regions offers a clear visualization of the spatial distribution of haemorrhage, aiding in surgical planning and treatment evaluation.

3D Slice Stacks: Displaying consecutive CT slices in a 3D stack format offers a volumetric view of haemorrhage distribution, enabling clinicians to navigate through the volume and examine haemorrhage morphology from different perspectives.

Tools and Software for Visualization:

3D Slicer: This open-source software platform provides extensive tools for medical image visualization and analysis. It supports a variety of visualization techniques and enables customization to meet specific clinical needs.

ITK-SNAP: Another open-source software, ITK-SNAP specializes in segmentation and visualization of medical images. It offers intuitive tools for delineating haemorrhage regions and provides advanced visualization options.

OsiriX: Widely used in the medical community, OsiriX is a comprehensive software for MacOS that offers advanced visualization capabilities for CT, MRI, and other imaging modalities. It enables interactive exploration of CT volumes and facilitates the identification of haemorrhage regions.

ImageJ/FIJI: These open-source software packages offer a wide range of image processing and analysis tools, including plugins for medical image visualization. They provide flexibility and extensibility for custom visualization workflows.

MATLAB: MATLAB is a powerful tool for medical image processing and visualization. With built-in functions and toolboxes, it allows for the development of custom visualization techniques and integration with other analysis tools.

Python Libraries: Python libraries such as SimpleITK, PyRadiomics, and PyVista offer capabilities for medical image visualization and analysis. They provide a flexible and efficient platform for developing custom visualization solutions and integrating with deep learning frameworks for automated haemorrhage detection and visualization. These visualization techniques and tools are essential for interpreting CT brain images and aiding clinicians in the accurate diagnosis and treatment of intracranial haemorrhage.

They enable detailed analysis of haemorrhage morphology, localization, and distribution, ultimately improving patient care and outcomes.

INTEGRATION AND PERFORMANCE EVALUATION:

Integration of Segmentation and Classification Methods:

In medical imaging, the integration of segmentation and classification methods plays a pivotal role in automating the analysis of complex structures like intracranial haemorrhages (ICH). Segmentation algorithms delineate regions of interest within images, outlining potential areas of haemorrhage. These regions, however, lack context regarding the type or severity of haemorrhage. This is where classification methods come in. They analyze the segmented regions, discerning nuances like the type (e.g., epidural, subdural) and severity (e.g., mild, moderate, severe) of haemorrhage. Integrating these methodologies ensures a comprehensive understanding of ICH cases. For instance, a segmented region might indicate the presence of haemorrhage, but without classification, its clinical significance remains uncertain. By combining segmentation and classification, clinicians gain detailed

insights into the nature and extent of haemorrhage, aiding in accurate diagnosis and treatment planning.

Classification is a technique that classify the two-class such as Grayscale normal CT brain image and ICH brain image.

Evaluation of the Combined System's Performance

Assessing the performance of an integrated system is crucial for validating its efficacy in clinical practice. Various metrics are employed to gauge different aspects of performance. Sensitivity measures the system's ability to correctly identify positive cases of ICH, ensuring that no true cases are missed. Specificity assesses the system's accuracy in identifying negative cases, minimizing false alarms. Accuracy provides an overall measure of correctness, indicating the system's reliability across both positive and negative cases. Additionally, the Dice similarity coefficient quantifies the agreement between the system's segmentation results and ground truth annotations, reflecting the system's ability to accurately delineate haemorrhage regions. By comprehensively evaluating these metrics, clinicians can assess the integrated system's reliability, sensitivity, and specificity, crucial for its adoption in clinical workflows.

Comparative Analysis with Existing Approaches

Innovation in medical imaging is iterative, with new methodologies constantly emerging. Hence, it's essential to compare the performance of the integrated system with existing approaches to demonstrate its superiority or competitiveness. Traditional machine learning methods, such as support vector machines or random forests, have been widely used for ICH detection. Deep learning techniques,

particularly convolutional neural networks (CNNs), have also shown promising results in recent years. Comparative analysis involves evaluating factors like computational efficiency, accuracy, robustness to noise, and generalization to unseen data. By benchmarking the integrated system against established methods, researchers can showcase its advancements and potential clinical impact. Additionally, highlighting its strengths and limitations in comparison to existing approaches informs future research directions and facilitates the continuous refinement of medical imaging algorithms.

In summary, the integration of segmentation and classification methods in ICH detection allows for more accurate and detailed analysis of CT brain images, leading to improved diagnostic outcomes.

CONCLUSION AND SCOPE FUTURE WORK

Thus, the Intracranial Haemorrhage CT brain image to be digitally acquired, segmented, classified, 3D visualization, and volumetric analysis can be done. ICH segmentation for all 2D slices from a single CT scan done by K means clustering method, Further classification done by SVM classifier, and Finally proposed a 3D visualization using iso surface technique. These processes can be done by using the MATLAB tool. The achieved results shows that proposed system is a good segmentation, 3D Visualization and found the area, volume, depth of occurrence efficiently. The resultant output helps a doctor to determine the type of haemorrhage and its depth of occurrence. Moreover, an easy tool that can aid the surgeon to take the proper course of action can help reduce to provide better therapeutic planning and reduced mortality rate.

The future work would be to increase the accuracy of classification for accurate classified between normal brain and ICH brain. Need to improve ICH segmentation while multiple haemorrhage in single slice. Enhance the location of 3D ICH in all direction for implementing successful surgical procedure.

ABSTRACT

Medication errors continue to pose significant challenges in healthcare, warranting innovative solutions to enhance patient safety and streamline medication administration processes. This research introduces an Automatic Medicine Dispensing System leveraging QR code technology to verify patient identity and medication information, enabling precise dispensation without the reliance on a doctor's written prescription. The system incorporates a secure QR code verification mechanism, allowing patients to present their unique QR codes containing encrypted medication details to the dispensing system. Employing specialized software and hardware, the system interprets QR codes to dispense prescribed medications at designated times accurately. This advanced approach aims to mitigate risks associated with manual prescription errors and streamline medication administration, ultimately contributing to improved patient safety within healthcare settings.

KEYWORDS

QR Code Scanner, QR Code Generator, Servo Motor, Arduino IDE, Raspberry Pi.

INTRODUCTION

In the domain of healthcare, the prevalence of medication errors emerges as a critical public health challenge, leading to numerous injuries and fatalities annually. Addressing this concern necessitates innovative solutions, and one such avenue is the incorporation of Automated Medication Dispensing Systems (AMDSs). These advanced computer-driven systems are meticulously designed to securely store, dispense, and monitor medications in diverse healthcare settings, including hospitals, pharmacies, and nursing homes.

This research project introduces a pioneering variant of AMDSs, leveraging QR codes as a robust medium for transmitting prescription details from physicians to patients. Physicians generate QR codes containing comprehensive prescription information, encompassing medication names, dosages, and instructions. Subsequently, patients present these QR codes to the AMDS, where the system scans and interprets the codes, facilitating precise medication dispensation. The technological foundation of this endeavor encompasses QR codes for information encoding, specialized software for data management, and QR code generation, along with requisite hardware for medication dispensing, QR code scanning, and seamless system communication.

This novel approach holds substantial promise, primarily offering a tangible reduction in medication errors. The utilization of QR codes ensures a secure and precise means of transmitting prescription data, thereby mitigating risks associated with illegible prescriptions or misinterpretations. Simultaneously, the proposed AMDS contributes to advancing patient safety by guaranteeing the accurate administration of medications at prescribed times.

LITERATURE REVIEW

Automated medication dispensing systems are pivotal in resolving critical issues like ensuring patients take their medication as prescribed, accurate dosing, and remote monitoring. One innovative design combines IoT technology with Arduino

boards and Real-Time Clock modules, using Firebase as an IoT gateway. This system focuses on the precise delivery of both solid and liquid medications, featuring a user-friendly app integration and alarm notifications. Using components like Servo Motors, Centrifugal Pumps, Real-Time Clock Modules, Node MCUs, and Arduino UNOs, this system aims to remind patients and alert caregivers in case of missed doses. However, concerns over cybersecurity threats and initial costs remain, urging further exploration and strategies for widespread adoption. Another approach incorporates surveillance features via ESP CAM 32 and L293D motor drivers, enhancing medication dispensation systems with remote monitoring capabilities. Integrating GSM, RTC, and stepper motors, this system prioritizes accurate medication delivery, patient adherence, and automated notifications. While these advancements are promising, complexities in technical setup and initial costs may hinder widespread adoption in healthcare and home settings.

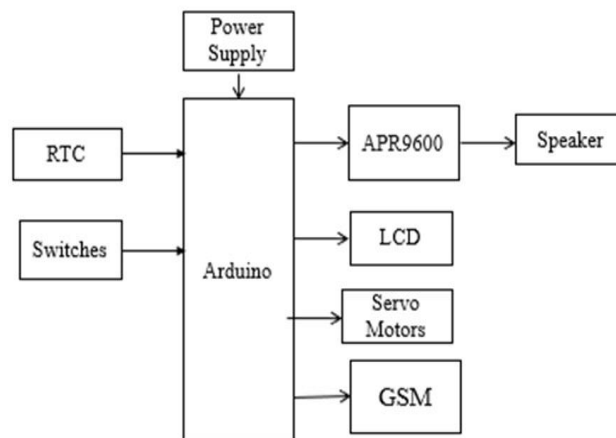

FIGURE 1. BLOCK DIAGRAM OF THE INTEGRATED SYSTEM.

Additionally, research on closed-loop EMMS and ADCs in hospitals emphasizes their effectiveness in managing controlled medications. These systems prioritize secure storage, accurate record-keeping, and streamlined workflows for healthcare professionals. Nevertheless, challenges persist, especially regarding data security, ongoing subscription fees for cloud services, and regular maintenance needs,

requiring robust strategies for cybersecurity and cost-effective maintenance protocols.

PROPOSED METHODOLOGY

The development of the Automatic Drug Dispenser with QR Code Scanner and Generator (ADDSQ) comprises a structured methodology designed to redefine medication management and enhance patient safety. The system's core architecture revolves around a microcontroller-based control unit to revolutionize the medication administration process.

The methodology integrates cutting-edge technologies to replace traditional written prescriptions with QR codes, ensuring enhanced accuracy and efficiency. The system is meticulously designed to handle both solid and liquid medications. Central to its functionality is a QR code scanner and generator, enabling seamless prescription authentication and precise medication dispensation. Healthcare providers encode prescription details into QR codes, simplifying data input and enhancing system interoperability.

The medication dispensing mechanism is engineered with precision, facilitating the accurate administration of prescribed dosages stored within QR codes. The system's design includes dedicated compartments for solid medications and specialized dispensers for the controlled release of liquid medications, ensuring meticulous dosage adherence.

A user-centric interface is prioritized, allowing effortless QR code scanning for prescription retrieval and medication dispensation. Stringent security protocols are embedded, granting exclusive access to authorized personnel while safeguarding against unauthorized usage or access.

Moreover, robust data management capabilities are integrated to securely store patient profiles, prescribed dosages, and medication histories. This system undergoes comprehensive testing to validate accurate dispensing, adherence to

prescription instructions, and user-friendly operation, ensuring reliability and precision in medication administration.

The ADDSQ system's distinctive features encompass seamless QR code integration, precise medication dispensation for both solid and liquid medications, user-friendly interfaces, stringent security measures, and robust data management capabilities. Its operational efficiency, extended battery life, and advanced technology integration contribute to a paradigm shift in medication management, aiming to elevate patient adherence and mitigate medication-related risks significantly.

Arduino Uno

The Arduino/Genuino Uno is a microcontroller board centered around the ATmega328P, featuring 14 digital input/output pins (6 PWM capable), 6 analog inputs, a 16 MHz quartz crystal, USB connection, power jack, ICSP header, and reset button. It's a versatile board, easily connectable to a computer via USB or powered by an AC-to-DC adapter or battery. Operating between 6 to 20 volts, a recommended range of 7 to 12 volts ensures stability; lower voltage might cause instability, while higher voltage could damage the board's regulator.

The IOREF pin provides voltage reference. RX/TX pins handle TTL serial data, while external interrupts (pins 2 and 3) allow for configurable triggers. PWM pins (3, 5, 6, 9, 10, 11) provide 8-bit PWM output, and SPI pins (10, 11, 12, 13) support SPI communication. The board includes a built-in LED (pin 13) and facilitates TWI communication (A4/SDA, A5/SCL) via the Wire library. With 6 analog inputs (A0-A5) offering 10-bit resolution and UART TTL serial communication on digital pins 0 (RX) and 1 (TX), the Arduino/Genuino Uno is a versatile microcontroller ideal for diverse applications.

LCD Display

A Liquid Crystal Display (LCD) is a sleek electronic visual interface, that harnesses Liquid Crystals' light-modulating prowess. LCs, non-emissive, excel in diverse applications like monitors, TVs, aircraft displays, and portable devices. Compact, lightweight, and cost-effective, LCDs dominate consumer tech, from clocks to gaming devices. Their advantages over CRT and plasma include varied screen sizes, burn-in immunity, energy efficiency, and eco-friendly disposal. Ideal for battery-powered gadgets, LCDs are digitally controlled optics, with pixels of liquid crystals aligned before a light source.

This dynamic interplay produces vibrant or monochromatic images, facilitated by a backlight. Inherently reliable and easy on the eyes, LCDs stand as a testament to modern display technology's evolution.

Power Supply

A power supply is a crucial component that transforms electrical energy from one form to another, accommodating diverse sources such as solar, mechanical, or chemical. Commonly integrated into the powered device, like computer power supplies, it converts AC to DC. Typically situated at the rear of a computer case alongside cooling fans, these supplies play a pivotal role in delivering electrical power to components. Featuring an input voltage switch, they allow users to adapt to varying power outlets worldwide, with settings like 110v/115v or 220v/240v. The

switch's position becomes critical due to the voltage disparities among global power systems.

RTC Module

Real-Time Clocks (RTCs) are integrated circuit modules that function as precise clocks and calendars, managing timekeeping even during power outages. Fueled by a backup battery, typically a 3V lithium coin cell, these RTCs require minimal current to operate when the main system is powered off. This resilient feature is akin to the small coin cell found on computer motherboards. A notable example is the DS1307, a low-power clock/calendar with 56 bytes of battery-backed SRAM.

Its capabilities include tracking seconds, minutes, hours, days, dates, months, and years, with automatic adjustments for month-end dates and leap years. Serving as a slave device on the I2C bus, the DS1307 ensures reliable timekeeping in diverse embedded systems, embodying the crucial marriage of accuracy and continuity in electronic time management.

Servo Motor

A servo motor offers precise rotation controlled by feedback on its shaft position. It's commonly used to achieve specific angles or distances in objects. There are DC and AC servo motors, with variations based on gear arrangement for compact, high-torque options. Rated in kg/cm, these motors can lift weights according to the distance from their shaft. For instance, a 6kg/cm servo can lift 6kg at a 1cm distance, with decreased capacity as the distance increases. Servo motors' positions are determined by electrical pulses, and their circuitry is positioned alongside the motor. They find applications in toy cars, RC devices, robotics, and more.

QR Code generator

The QR code generator comprises several key components, including a user interface for interaction, a QR code generation library responsible for creating QR codes from user-provided data, a data input mechanism allowing users to input the data they want to encode, a QR code renderer to visually display the generated QR

code, optional customization features for adjusting the QR code's appearance with colors or logos, and a save/export function to enable users to store or export the QR code.

The workflow involves users inputting data, which is then processed by the generator software using the QR Code Generation Library to produce a QR code that's displayed on the user interface. Customization options are available, and users can save or export the QR code for later use.

QR Code Scanner

The QR code scanner consists of essential components, such as a device camera used to capture QR codes, a QR code recognition library that analyzes camera input to detect and decode QR codes, a user interface for displaying the scanned data, and an action handler to determine how to interact with the decoded information, such as opening URLs, adding contacts, or displaying text.

The workflow starts with the user launching the QR code scanner application, and activating the device's camera for continuous scanning. When a QR code is detected, the Recognition Library decodes the information, which is then displayed in the user interface. Depending on the data type, the Action Handler initiates appropriate actions, providing a seamless and efficient means of interacting with QR codes.

Arduino Software (IDE)

The Arduino IDE, an open-source software, serves as a user-friendly platform to write and compile code for Arduino modules. Its accessibility allows beginners without technical backgrounds to dive into the learning process easily. Compatible with MAC, Windows, and Linux, the IDE operates on the Java Platform, offering built-in functions for debugging, editing, and code compilation. It supports various Arduino modules like Uno, Mega, and Leonardo.

The core functionality involves creating a sketch on the IDE, generating a Hex File, and uploading it to the controller on the board. The IDE comprises two primary

components: the Editor for code writing and the Compiler for code compilation and uploading to the Arduino Module.

Using the concept of a "sketchbook," the IDE provides a standardized location to store programs. This sketchbook, accessible through the File menu, stores sketches with a .ino file extension in version 1.0 and later, while older versions use the .pde extension. The software accommodates both extensions, automatically converting .pde files to .ino upon opening in versions 1.0 and beyond.

Embedded C

Embedded C stands out as the predominant programming language in the software domain for crafting electronic devices. Every processor within an electronic system relies on embedded software to execute tailored functions. From mobile phones to washing machines and digital cameras, our daily interactions with electronic devices hinge on microcontrollers programmed through Embedded C, showcasing its pivotal role in shaping modern technology.

RESULTS AND DISCUSSION

The results of the Automatic Drug Dispenser reveal a significant reduction in medical errors, attributed to the implementation of a QR code system instead of traditional written prescriptions by doctors. The programmable nature of the system emerges as a key advantage, enabling the adjustment of both pill quantity and dispensing frequency. Graphing the data with time on the X-axis and medical error on the Y-axis illustrates a noteworthy contrast between instances with and without QR codes.

FIGURE 3. COMPARISON OF ERROR DUE TO PRESCRIPTION AND QRCODE

The blue color bar represents scenarios without QR codes, while the orange color bar signifies those with QR codes. This graphical representation emphasizes the efficacy of QR codes in preventing medication errors and underscores the potential impact on patient well-being.

CONCLUSION

The advent of an automated medication dispenser marks a pivotal stride in enhancing medication adherence and patient safety. This user-friendly device is adept at dispensing multiple medications at designated intervals, offering a streamlined approach to medication management. With built-in safety features like a secure locking mechanism and a preventive system for medication interactions, the device mitigates the risk of errors. The utilization of such automatic dispensers not only minimizes medication-related discrepancies but also contributes to enhanced patient outcomes. Moreover, automating this aspect of healthcare, allows healthcare providers to allocate more time and attention to other critical facets of patient care.

ABSTRACT

Stroke risk may be predicted and detected early, which can greatly enhance patient outcomes and lessen the strain on healthcare systems. By utilizing deep learning techniques—more particularly, Convolutional Neural Networks (CNN) and Long Short-Term Memory networks (LSTM)—applied to Electrocardiogram (ECG) bio data, this study offers a unique method for stroke prediction. An extensive dataset of ECG signals from people with a history of strokes and a control group are acquired and preprocessed for the investigation. Relevant characteristics are extracted from the ECG signals using data mining algorithms, which also capture spatial and temporal patterns suggestive of cardiovascular problems. The LSTM is used to model the temporal relationships within the ECG data, while the CNN is used to automatically learn hierarchical representations of local characteristics. By merging the advantages of LSTM for temporal dependency detection and CNN for spatial feature extraction, the suggested model seeks to improve prediction accuracy. Using a labeled dataset with backpropagation to optimize the model parameters for supervised learning is the training phase. Sensitivity, specificity, and accuracy and other metrics are used to evaluate the results and contrast the CNN and LSTM-based model with other, more traditional approaches. The study contributes to the

growing corpus of research on the use of deep learning in healthcare and sheds light on the potential of ECG bio signals for early stroke risk detection.

INTRODUCTION

A stroke is a medical illness where anomalies in the blood arteries in the brain cause malfunction in certain parts of the brain. Stroke is the third most prevalent cause of disability worldwide and the second most common cause of death worldwide, according to a 2016 World Health Organization (WHO) report. Over the previous 40 years, the incidence of stroke has more than doubled in emerging nations. Early identification is crucial for stroke because there is currently no effective therapy for the condition. The most widely used procedures for detecting stroke disease are CT and MRI scans. But because CT and MRI are costly, they might not be appropriate for those in underdeveloped nations or with modest incomes. Stroke illness is becoming a major global health concern, especially for the elderly and those with little resources. As such, healthcare providers are in dire need of a low-cost, fast, and reliable way to identify stroke cases. Among these techniques, brain imaging (CT, MRI, X-ray), ECG, EEG, and neurological physiological methods (induced potential tests) can all be used to identify stroke disease. The most commonly used techniques to diagnose stroke are CT and MRI, but these involve risks such as radiation exposure or potential allergic reactions to the contrast agents used; additionally, these tools can be inconvenient due to confined spaces, constant monitoring, and separate medical costs for each examination, all of which increase the difficulty of diagnosis. Fortunately, new wearable electrodes offer an opportunity to measure EEG in the comfort of a participant's home. There are two types of stroke diseases: ischemic stroke and haemorrhagic stroke. Emergency care for stroke patients should include the type-specific delivery of coagulants or

thrombolytics. First and foremost, it is critical to identify the early warning signs of a stroke in real time, as each person experiences these symptoms differently, and to receive expert care from a medical facility within the appropriate treatment window.

After donning bio signals sensors, each subject's bio signals were measured five times for each scenario, including sleeping, standing steadily, walking, chatting, raising arms and legs, and sitting and standing, in order to ensure the impartiality of the process. Each scenario required a single pre-rehearsal from the subjects. The initial measured and collected bio-signals values were not employed in the experiment, despite their past experience, since human noise may arise from the subject's discomfort from wearing the sensor and the tense condition. Because it is quite possible that the subjects' weariness would be represented in the bio-signals data owing to their advanced age and the recurrence of trials, the last measurement procedure was not reflected in the experimental and performance verification data.

METHODOLOGY

In order to assess and interpret ECG data and eventually forecast the chance of a stroke, the goal is to make use of cutting-edge deep learning algorithms. With data mining approaches, relevant patterns and information are extracted from electrocardiogram (ECG) signals to create a CNN and LSTM-based stroke illness prediction utilizing ECG bio signals. Using ECG data, the objective is to develop a prediction model that can correctly identify those who are at risk of stroke.

In this proposal, we defined and found 29 novel qualities that were not utilized in prior multi-modal bio-signals based research on ECG and PPG for machine learning and deep learning approaches. This is an important addition because, by giving medical personnel access to the findings of semantic analysis, it may be actively employed for objective diagnosis and predictive therapy. The stroke prediction and monitoring system presented in this research has been experimentally proven to be useful for low-cost everyday health care services as well as real-time prognostic symptom prediction of stroke illness. The bio signals of the PPG and ECG, which

were recorded in real time while senior citizens 65 years of age or older were walking, were the data used in this investigation.

For every multimodal bio-signal, including ECG and PPG from senior patients and older adults who have had strokes, the suggested system measures, collects, and preprocesses data to store and maintain important properties. Using machine learning and preprocessing raw data-based deep learning models based on each bio-signal's characteristics, it was also intended to forecast and evaluate stroke prognostic symptoms in real-time.

There are five consecutive phases in the model construction process:

Choosing the data for the supervised learning's input and output.

Data normalization for both the input and output.

Applying neural network learning to train the normalized data.

Checking the model's quality of fit.

Evaluating the difference between the intended and projected results.

Layers, or subgroups of processing modules, make up a layered feed forward neural network. After performing separate calculations on the input it receives, one layer of processing components transfers the outcome to another layer. Subsequent layers have the ability to do autonomous calculations and transmit the outcome to subsequent layers. Ultimately, the output of the network is determined by a subgroup of one or more processing components.

Steps in neural network algorithm:

Step 1: Randomly initialize the weights and biases.

Step 2: feed the training sample.

Step 3: Forward the inputs and calculate each unit's net input and output in the hidden and output layers.

Step 4: back propagate the mistake to the layer that is concealed.

Step 5: Adjust the biases and weights to account for the propagating mistakes. The weights and biases of the network are automatically adjusted using mathematical processes called training and learning functions.

Step 6: Terminating condition: The neural network method performs better than the conventional machine learning algorithms based on these phases.

PROPOSED METHODOLOGY

A neural network is a computer method that uses a sizable number of neural units to simulate how the brain uses huge clusters of biological neurons connected by axons to solve issues. Numerous neuronal units are linked to each other. The effect of links on the activation state of linked neuronal units can be either enforcing or inhibitory. A summing function that combines the values of each neural unit's inputs may be present. a limiting or threshold function that must be exceeded on both the unit and each link in order for the signal to reach additional neurons.

DATASET AQUITION

A dataset, often spelled "data set," is a grouping of data; many modern dictionaries, including Merriam-Webster, do not use this form. A single database table or statistical data matrix, with each column denoting a different variable and each row designating a specific member of the data set under consideration, is

typically used to describe the contents of a data set. Every member of the data set has their values for every variable included in the data set, including object weight and height. A datum is a name for any value. Depending on the number of rows in the data collection, data for one or more members may be included. Depending on the number of rows, the data set may include information for one or more members. The data in a group of tightly connected tables that pertain to a certain experiment or event can also be referred to as a "data set" in a broader sense. We may upload cardiovascular datasets pertaining to heart disorders into this module. These datasets contain parameters like age, gender, height, weight, systolic and diastolic blood pressure, cholesterol, glucose, alcohol, smoking, active status, and cardio labels.

PREPROCESSING

An essential phase in the [data mining] process is data pre-processing. For data mining and machine learning projects in particular, the adage "garbage in, garbage out" holds true. A lot of the time, data collection techniques are not well regulated, which leads to missing values, impossible data combinations, and out-of-range numbers. Results from data analysis that hasn't been thoroughly checked for these issues may be deceptive. Therefore, before doing an analysis, the quality and representation of the data should come first. Knowledge discovery during the training phase is more challenging if there is a large amount of redundant and irrelevant information available, or noisy and untrustworthy data. Processing time can be significantly increased by the procedures involved in data preparation and filtering. This module allows us to estimate the missing values in the data and remove unnecessary items. Lastly, offer datasets that are structured.

FEATURES SELECTION

The process of narrowing down the inputs for processing and analysis, or identifying the most significant inputs, is known as feature selection. The process of

extracting valuable information or features from preexisting data is referred to as feature engineering, sometimes known as feature extraction. Statistical measures are used in filter feature selection procedures to give each feature a score. The score is used to rank the characteristics, after which they are either retained in the dataset or deleted. The techniques are frequently univariate and take the feature into account either alone or in relation to the dependent variable. It can be applied to the construction of various cardiac conditions. Choose the various characteristics from the uploaded datasets in this module. Additionally, train the datasets using a variety of illness labels, including normal, arrhythmia, high blood pressure, cardiac arrest, and coronary heart disease.

CLASSIFICATION

This module uses a classification system to forecast cardiac disease. Also use deep learning algorithms to forecast illnesses, like as the Multi-layer Perceptron algorithm. A feed forward artificial neural network model called a multilayer perceptron (MLP) translates sets of input data onto a collection of suitable outputs. Each layer in the multilayer graph (MLP) is fully linked to every other layer through a directed graph. With the exception of the input nodes, each node is a neuron with a nonlinear activation function. MLP trains the network via back propagation, a supervised learning approach.

A modified version of the basic linear perceptron, the MLP is capable of separating non-linearly separable data. Subsequently, the gradient approaches are employed in conjunction with optimization methods to modify weights in order to reduce the network's loss function. For the technique to compute the gradient of the loss function, a known and a desired output for each input is therefore necessary. Typically, a delta rule is used to generalize Multi-layered Feed Forward Networks, potentially creating a series of iterative rules to calculate gradients for every layer.

The Back Propagation Algorithm requires that each neuron's activation function be unique. Multilayer Perceptron principles are now being used to ongoing research

on computational neuroscience and parallel, distributed computing utilizing a Back Propagation Algorithm. In the field of pattern recognition, the MLP Back Propagation Algorithm has also attracted attention. Their capacity to solve complicated issues and their fitness approximation findings, even with crucial predictions, make them extremely useful in research. One of the Neural Network models, MLP, uses the same Feed-Forward back Propagation architecture for Supervised training. The most popular and often utilized kind of neural network is the multilayer perceptron. The user has the ability to input information and make automated illness predictions.

PYTHON LIBRARIES FOR DATA ANALYSIS

Python is an easy-to-learn programming language that allows you to conduct some fundamental operations such as adding and printing statements. However, if you want to perform data analysis, you need to import specific libraries. Some examples include:

Pandas - Used for structured data operations

NumPy - A powerful library that helps you create n-dimensional arrays

SciPy - Provides scientific capabilities, like linear algebra and Fourier transform

Matplotlib - Primarily used for visualization purposes

Scikit-learn - Used to perform all machine learning activities

DISEASE DIAGNOSIS

A medical decision support system is a software application that helps doctors and other health professionals make decisions. Examples of these decisions include diagnosing patients' data. Provide the diagnosis details for the anticipated cardiac illnesses in this module. The proposed method improves the prediction of heart disease's accuracy. Risk factors are behaviours or situations that increase an individual's chance of contracting an illness.

REAL-TIME ECG AND PPG BIO-SIGNALS

The purpose of this study is to validate the efficacy of systems that offer AI-based prognostic and predictive data for older stroke disorders by measuring and gathering a variety of biological signals. Bio-signals data such as ECG, EEG, PPG, EMG, and movements are gathered. The real-time measurement and collecting procedure is covered in full in this section. EEG and PPG were two of the bio signals that were recorded and gathered in this study and utilized in tests to test the efficacy of a system designed to predict stroke illness. Previous research has documented the appearance of anomalies in the sympathetic and autonomic nervous systems during the prelude to or during a stroke. Accurately forecasting stroke symptoms with a single bio-signal is fraught with challenges. Relevant characteristic values were derived from two forms of multimodal bio-signals for this study: PPG, which measures blood volume variations with heart contraction and relaxation, and ECG, which may validate pulse rate and consistency. To reliably anticipate stroke prognostic symptoms and onset, we suggest utilizing a characteristic that integrates two bio-signals. Depending on where the attachment is placed, the ECG measuring technique is primarily split into standard 12-lead ECG and chest guidance. Within standard 12-lead ECG, there are two more subtypes: unipolar extremities guidance and bipolar standard guidance. The study used the chest guiding approach to accurately measure and gather the ECGs of senior stroke patients as well as the general elderly.

The three ECG electrode attachment locations utilized in the investigations in this work as shown in figure 1. The sensors were attached to the subjects' left and right index fingers, allowing the PPG bio-signals that were detected and gathered for this article to be saved in real time as shown in figure 2.

Fig 2. 3-electrode-based measurement and acquisition for ECG bio-signal acquisition.

Fig 3. PPG bio-signal measurement and collection.

EXTRACTION OF VALUES IN ECG AND PPG BIO-SIGNALS

Only the gait data from all the bio signals gathered in different scenarios such as resting, sleeping, sitting, moving things, and speaking were used in this study. In other words, stroke illness in the elderly was only predicted and analysed using the bio-signals of the ECG and PPG restricted to walking situations. Table 1 provides a detailed description of the 29 features and their meanings that were taken from the PPG bio-signals (Fig. 5) and the ECG data (Fig.

Now let's examine how the confusion matrix determines the model's accuracy.

The following will calculate the model's accuracy:

$(\text{True Positive (TP)} + \text{True Negative (TN)}) / \text{Total}$

$(103+18)/150 = 0.80$

When anything predicts "yes" and how frequently it is accurate, it is precise.

$\text{True Positive} / \text{Predicted Yes} = 103/130 = 0.79$

EXPERIMENT AND RESULT

DATA CONFIGURATION AND EXPERIMENTAL DESIGN

For the purpose of deep learning and machine learning-based stroke disability prediction, as well as comprehensive analysis and verification, this section explains the procedure for gathering and pre-processing multimodal bio-signals of ECGs and PPGs. Multimodal data from real-time measurements and collection of PPG and ECG bio signals were used in the research carried out in this work. When the heart beats, an electric current flow through the three intestines and shows as a wavy line. These bio-signals, which include the ECG and PPG, represent values that can represent the contraction and relaxation of the heart. Blood vessel volume variations in response to heartbeat are recorded by ECG and PPG in the peripheral areas, heart electrical circuit, and heart rhythm. Major cardiovascular disorders like arrhythmias or atrial fibrillation, as well as chronic illnesses like hypertension, can be detected by examining the bio-signals of the ECG and PPG. As a result, we used the clinical data from this study to demonstrate how anomalies in the sympathetic and autonomic

nervous systems might emerge from stroke prognostic signs. Using medical opinion and diagnostic results of aberrant symptoms, such as cardiac arrest or arrhythmia in ECG and PPG, we tried to anticipate the prognostic symptoms of stroke illness and explain their implications. Furthermore, the stroke prognostic and prediction tests in older patients were verified by a deep learning model utilizing the raw data of the bio-signals of the PPG and ECG.

In the Emergency Medical Centre and Department of Neurology and Rehabilitation Medicine at Chungnam National University in the Republic of Korea, multimodal bio signals of ECG and PPG were monitored and collected from elderly patients in 2017 and 2018. Bio signals, including ECG and PPG, EEG, EMG, motion, and foot pressure, were gathered from subjects who were elderly (65 years of age or older) and had received a stroke diagnosis during the previous month. Bio-signals from 287 senior stroke patients and 287 elderly normal individuals make up the experimental dataset.

In this study, normal old patients were classified as those receiving therapy for conditions other than stroke-related discomforts. After donning bio signals sensors, each subject's bio signals were measured five times for each scenario, including sleeping, standing steadily, walking, chatting, raising arms and legs, and sitting and standing, in order to ensure the impartiality of the process. Each scenario required a single pre-rehearsal from the subjects. The initial measured and collected bio-signals values were not employed in the experiment, despite their past experience, since human noise may arise from the subject's discomfort from wearing the sensor and the tense condition. Because it is quite possible that the subject's weariness would be represented in the bio-signals data owing to their advanced age and the recurrence of trials, the last measurement procedure was not reflected in the experimental and performance verification data.

EVALUTION MATRICES

The proposed method is evaluated using the following evaluation tools: Specificity, F1_score, sensitivity (Recall), accuracy, and precision Equation, which is well-defined as the number of acceptably, noticed or categorized images, indicates the framework's accuracy. F1_score, on the other hand, computes the weighted average of precision and recall by combining the two. These metrics can be estimated using these equations:

$$\text{Precision} = \text{TP} / (\text{TP} + \text{FP})$$

$$\text{Accuracy} = (\text{TN} + \text{TP}) / \text{TS}$$

$$\text{Sensitivity (recall)} = \text{TP} / (\text{TP} + \text{FN})$$

$$\text{F1 score} = 2 \cdot (\text{Precision Recall}) / (\text{Precision} + \text{Recall}) \quad \text{Specificity} = \text{TN} / (\text{TN} + \text{FP})$$

True positive, total samples, false positive, true negative, and false negative, respectively, are denoted by the letters TP, TS, FP, TN, and FN.

KERNEL	Accuracy	Precision	Sensitivity	Specificity	F1 Score
Linear	91%	95.4%	97%	87.53%	91.7%
Quadratic	81%	79.6%	87%	73.4%	83.3%
RBF	59%	89%	27%	96%	41%
Polynomial	87.9%	84.8%	94.7%	80%	89%

A confusion matrix, as the name suggests, is a matrix of numbers that tell us where a model gets confused. The confusion matrix is a structured method of mapping the predictions to the original classes. It is a class-wise distribution of a classification model's predictive performance. The data scientist may more easily visually grasp how the labels are being forecasted with the use of a normalized confusion matrix. It is used to increase the performance of the model in the machine learning. The prediction of result shown in the Fig 11.

CONCLUSION

A system that uses several biological signals, such as PPG and ECG, obtained from walking throughout daily life to offer a semantic analysis of illnesses in the elderly. The suggested method gathers numerous ECG and PPG bio-signals in real-time and has the ability to quickly identify and forecast prognostic signs of senior stroke patients. An important development in data mining for healthcare applications is the CNN and LSTM-based stroke disease prediction that uses ECG bio signals. Utilizing the capabilities of Long Short-Term Memory (LSTM) and Convolutional Neural Networks (CNNs), the model demonstrates a strong capacity to examine intricate temporal patterns in ECG data.

With CNNs integrated, it is possible to automatically extract hierarchical features from unprocessed ECG data, capturing both global and local patterns that are essential for precise diagnosis. Concurrently, the LSTM network enhances the model's ability to identify minute abnormalities linked to stroke risk by mastering the learning and comprehension of long-term dependencies within the sequential pattern of ECG data. This novel method tackles the inherent difficulties in predicting stroke illness using bio signals and also demonstrates the promise of deep learning

in the healthcare industry. Validated by means of stringent data mining approaches, the model's performance indicates that it is effective in risk assessment and early detection.

In this study, we have developed a machine learning algorithm-based model for stroke prediction. We chose five distinct models, including decision trees, random forests, logistic regression, support vector machines, and K closest neighbours, after carefully reading through several IEEE publications. Important characteristics were chosen with the advice of by using graphs, charts, and other visual aids to convey important/common trends and information, health data visualization enables professionals to better explain the dataset to even data analysts. Thus, our primary goal was data visualization. used matplotlib, seaborn, pandas, and Pywaffle tools to create visually appealing and educational data visualizations.

FUTURE ENHANCEMENT

In the future, we will use a variety of bio-signals, including motion, foot pressure, EEG, and EMG, as well as MRI image data and electronic medical records (EMRs) to do in-depth analysis and predicting tests of stroke illness.

ABSTRACT

Improving agricultural production can only be achieved using innovative environmentally suitable solutions and modern agricultural technologies. Using Internet of Things (IoT) technologies in greenhouse farming allows reduction of the immediate impact of external climatic conditions. Many rice blast management approaches require know-how of experienced farmers or agronomists. Monitoring the farm for disease detection is labor intensive and time consuming. By using IoT and artificial intelligence (AI), we are able to detect plant diseases more efficiently. Existing AI and IoT studies detect plant diseases by images or non-image hyper spectral data, which require manual operations to obtain the photos or data for analysis. This project will introduce the highly scalable intelligent system controlling, and monitoring greenhouse climatic condition using IoT technologies also non-image IoT devices to detect greenhouse plant diseases. Unlike the image-based plant disease detection approaches, our agriculture sensors generate non-image data that can be automatically trained and analyzed by the AI mechanism in real time. The first objective of this system is to monitor the greenhouse environment and control the internal temperature to reduce consumed energy while maintaining good conditions that improve productivity. The second objective is to provide the AI model is treated as an IoT device and is managed like other IoT devices. In this way, our approach significantly reduces the platform management cost to provide real-

time training and predictions. The design tries to organize various possible unstructured formats of raw data, collected from different kinds of IoT devices, unified and technology-independent fashion using the benefit of model transformations and model-driven architecture to transform data in structured form.

INTRODUCTION

Overview

Agricultural irrigation always receives attention as an important application for the purpose of crop cultivation and production. A reliable and suitable irrigation water supply can significantly raise vast improvements in agricultural productivity and water savings. Clearly, traditional irrigation consumes not only bulk amounts of water, but electrical energy may also be required greatly, depending on the geographical location. The traditional irrigation practice involves applying water as uniformly as possible over every part of the field without taking the variability of soil and crop water needs into account. Consequently, some parts of the field are over-irrigated, meanwhile, other parts of the field are under-irrigated.

In addition, variable rate irrigation (VRI) provides the flexibility to manage spatial and temporal variabilities within different zones of a production field. However, the adoption of VRI is very limited, and it does not always guarantee the best irrigation. Presently, water demands are continuously increasing, whereas water resources are unfortunately limited. With water scarcity, precision irrigation (PI) systems have been focused and enabled by the advancement of sensor technologies and the internet of things (IoT). Currently, the new paradigm of massive measurements is represented in terms of wireless sensor networks (WSN). As the rapid growth of IoT,

low-power and low-complexity communications are one of the greatest challenges faced by practitioners today.

Objective

The Internet of things (IoT) is network of objects, in which the objects of everyday life are embedded with microcontroller, sensors and software that enables these objects to collect and communicate data with one another and the users, becoming the essential part of the internet. The IoT model, aims at making the Internet even more persistent. Furthermore, by enabling easy access and communication with a wide range of devices such as, for example, home appliances, surveillance cameras, monitoring sensors and so on, the IoT is implemented for the development of applications that makes use of the enormous amount and the data generated by such objects provide services. This method finds application in many different areas, such as home automate, mobile healthcare, traffic management and many others.

Application

The protocol integrates sensors and IoT (Internet of Things) technology to monitor soil moisture levels, weather conditions, and plant requirements in real-time. This data is then analyzed to provide intelligent recommendations for irrigation scheduling.

I-SWAP optimizes water usage, reducing waste and conserving resources. This ensures that water is distributed efficiently, based on actual needs rather than predetermined schedules.

The implementation of I-SWAP supports the sustainability goals of smart cities by promoting responsible water management practices. By minimizing water usage for irrigation, it helps to mitigate the strain on local water sources

The application features an intuitive interface that allows users, such as city planners, landscape architects, and farmers, to easily access and interpret relevant data. This empowers users to make informed decisions regarding irrigation strategies and resource allocation.

I-SWAP is designed to be scalable and adaptable to various urban environments and agricultural contexts. Whether deployed in large-scale urban farms, community gardens, or public parks, the protocol can be customized to suit specific needs and requirements.

INTERNET OF THINGS (IoT)

Today, Internet application development demand is very high. So IoT is a major technology by which we can produce various useful internet applications. Basically, IoT is a network in which all physical objects are connected to the internet through network devices or routers and exchange data. IoT allows objects to be controlled remotely across existing network infrastructure. IoT is a very good and intelligent technique which reduces human effort as well as easy access to physical devices. This technique also has autonomous control feature by which any device can control without any human interaction.

The above figure shows the connectivity of various devices of different fields with Internet and exchange data between them. So above figure represent the connectivity of world through various existing technologies.

“Things” in the IoT sense, is the mixture of hardware, software, data, and services. “Things” can refer to a wide variety of devices such as DNA analysis devices for environmental monitoring, electric clamps in coastal waters, Arduino chips in home automation and many other. These devices gather useful data with the help of various existing technologies and share that data between other devices. Examples

include Home Automation System which uses Wi-Fi or Bluetooth for exchange data between various devices of home.

The 'Thing' in IoT can be any device with any kind of built-in-sensors with the ability to collect and transfer data over a network without manual intervention. The embedded technology in the object helps them to interact with internal states and the external environment, which in turn helps in decisions making process.

In a nutshell, IoT is a concept that connects all the devices to the internet and let them communicate with each other over the internet. IoT is a giant network of connected devices – all of which gather and share data about how they are used and the environments in which they are operated.

By doing so, each of your devices will be learning from the experience of other devices, as humans do. IoT is trying to expand the interdependence in human- i.e interact, contribute and collaborate to things. I know this sounds a bit complicated, let's understand this with an example.

A developer submits the application with a document containing the standards, logic, errors & exceptions handled by him to the tester. Again, if there are any issues Tester communicates it back to the Developer. It takes multiple iterations & in this manner a smart application is created.

Similarly, a room temperature sensor gathers the data and send it across the network, which is then used by multiple device sensors to adjust their temperatures accordingly.

For example, refrigerator's sensor can gather the data regarding the outside temperature and accordingly adjust the refrigerator's temperature. Similarly, your air conditioners can also adjust its temperature accordingly. This is how devices can interact, contribute & collaborate.

LITERATURE SURVEY

CONTROLLED MOBILITY TIME SYNCHRONIZATION FOR WSNS. Gopal Chand Gautam, Narottam Chand Kaushal. Scientific Research - Wireless Sensor Network, Vol.9 No.1, January 2017. One of the important aspects in wireless sensor networks is time synchronization. Many applications such as military activity monitoring, environmental monitoring and forest fire monitoring require highly accurate time synchronization. Time synchronization assures that all the sensor nodes in wireless sensor network have the same clock time. It is not only essential for aforementioned applications but it is mandatory for TDMA scheduling and proper duty cycle coordination. Time synchronization is a challenging problem due to energy constraints. Most of the existing synchronization protocols use fixed nodes for synchronization, but in the proposed synchronization, algorithm mobile nodes are used to synchronize the stationary nodes in the sensing field. In this paper, we propose a new time synchronization algorithm, named controlled mobility time synchronization (CMTS) with the objective to achieve the higher accuracy while synchronizing the nodes.

A HYBRID WIRELESS NETWORKING INFRASTRUCTURE FOR GREENHOUSE MANAGEMENT USING ARM. International Journal Of Advanced Research and Innovation, December 2015. G.Mounika, V.Arun. The

technological development in Wireless Sensor Networks made it possible to use in monitoring and control of greenhouse parameter in precision agriculture. Due to uneven natural distribution of rain water it is very crucial for farmers to monitor and control the equal distribution of water to all crops in the whole farm or as per the requirement of the crop. All the parameters of greenhouse require a detailed analysis in order to choose the correct method. With the evolution in wireless sensor technologies and miniaturized sensor devices, it is possible to use them for automatic environment monitoring and controlling the parameters of greenhouse, for Precision Agriculture (PA) application. In the Field bus concept, the data transfer is mainly controlled by a suitable wired communication system, now can be replaced with the hybrid system(wired and wireless) to extract the benefits of both and to automate the system performance and throughput. ZigBee protocols based on IEEE 802.15.4 – 2003 for wireless system are used. The atmospheric conditions are monitored and controlled online by using Ethernet IEEE 802.3. Partial Root Zone Drying Process can be implemented to save water at the maximum extent.

LONG TERM AND LARGE SCALE TIME SYNCHRONIZATION IN WIRELESS SENSOR NETWORKS. G. Huang, A. Y. Zomaya, F. C. Delicato, and P. F. Pires. Computer Communications, vol. 37, pp. 77–91, 2014. Time synchronization is very important in wireless sensor networks (WSNs). Many applications, for example natural disaster monitoring and structural health monitoring of huge buildings, require a highly accurate, long-term and large-scale time synchronization among the sensor nodes that compose the network. In this paper, we propose a new time synchronization protocol, named 2LTSP (long term and large scale time synchronization protocol), which aims at addressing such requirements. Theoretical analysis and simulation results show that when the synchronization period is less than 100 s, the error of 2LTSP is within 0.6 ms, no matter how large the size of the network is. Besides, when the required synchronization error limit is 9 ms, the communication cost of 2LTSP is less than 3 packets per hour in networks of any size.

Therefore, 2LTSP is highly accurate and energy-efficient even for large-scale and long-term running networks

METHODOLOGY

Proposed Method

Basically, it is assumed that the proposed greenhouse system for controlling and monitoring temperature consists of three main subsystems, namely, temperature control & monitoring subsystem, greenhouse management information system, and data conversion subsystem, rather than starting the design description using collaborated classes and responsibilities.

Greenhouse vegetables, whether grown in soil or in a hydroponic system, will not do as well during the winter as in the summer. Shorter days and cloudy weather reduce the light intensity and thus limit production. Most vegetables will do better if grown from January to June or from July to December than if they are started in the fall and grown through the midwinter months.

Providing the plants with an adequate amount of water is not difficult in the water culture system, but it can be a problem with the aggregate culture method. During the hot summer months a large tomato plant may use one-half gallon of water per day. If the aggregate is not kept sufficiently moist, the plant roots will dry out and some will die. Even after the proper moisture level has been restored, the plants will recover slowly and production will be reduced.

Therefore, the main contributions of this project, that reduce the knowledge gap between low-cost commercial available and system designs, are listed as follows.

A fuzzy-based Petri Nets (PN) intelligent irrigation scheduling system is designed and implemented using a low-cost WSN.

Crop water stress index (CWSI) and soil moisture content are simultaneously considered as variables for irrigation scheduling strategy.

The prototype of the proposed system is constructed and validated to gather data on the performance and functionality of the design.

The proposed irrigation scheduling system is experimentally tested to evaluate its effectiveness.

The comparative study is performed to explore the efficiencies of the proposed irrigation scheduling system in terms of water use and energy consumption.

The cost analysis is performed to assess the economic viability of an investment.

Proposed explanation:

The paper proposes a novel method for replacing traditional miniature circuit breakers (MCBs) by incorporating embedded systems and the Internet of Things (IoT). The described model not only serves as a substitute for conventional MCBs but also offers improved functionality. An automation tool, implemented as programmable software, connects the device to the user's email account, providing notifications when the voltage exceeds a user-defined extremely high threshold (e.g., 240 V). Continuous email notifications are sent until the voltage drops below the set level. Additionally, in the event of extremely high voltage, all connected electrical appliances automatically turn off to prevent damage. As the voltage decreases, appliances within their desired voltage range automatically turn on without user

intervention. The model's scalability is achieved through the use of "N" channels relay, allowing simultaneous connection and operation of multiple electrical appliances with different voltage requirements. In summary, this innovative methodology not only replaces MCBs but introduces advanced features such as automated notifications, safety shutdown, and scalable operation of diverse appliances, promising enhanced electrical system management and user convenience.

Hardware Descriptions

Power Supplies

A power supply (sometimes known as a power supply unit or PSU) is a device or system that supplies electrical or other types of energy to an output load or group of loads. The term is most commonly applied to electrical energy supplies, less often to mechanical ones, and rarely to others.

This circuit is a small +5V power supply, which is useful when experimenting with digital electronics. Small inexpensive wall transformers with variable output voltage are available from any electronics shop and supermarket. Those transformers are easily available, but usually their voltage regulation is very poor, which makes them not very usable for digital circuit experimenter unless a better regulation can be achieved in some way. The following circuit is the answer to the problem.

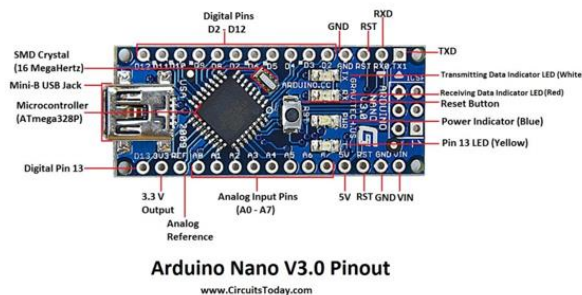

Fig 2: power supply

Arduino Nano

Arduino Nano has similar functionalities as Arduino Duemilanove but with a different package. The Nano is inbuilt with the ATmega328P microcontroller, same

as the Arduino UNO. The main difference between them is that the UNO board is presented in PDIP (Plastic Dual-In-line Package) form with 30 pins and Nano is available in TQFP (plastic quad flat pack) with 32 pins. The extra 2 pins of Arduino Nano serve for the ADC functionalities, while UNO has 6 ADC ports but Nano has 8 ADC ports. The Nano board doesn't have a DC power jack as other Arduino boards, but instead has a mini-USB port. This port is used for both programming and serial monitoring. The fascinating feature in Nano is that it will choose the strongest power source with its potential difference, and the power source selecting jumper is invalid

Temperature Sensor

A temperature sensor is a device which is designed specifically to measure the hotness or coldness of an object. LM35 is a precision IC temperature sensor with its output proportional to the temperature (in °C). With LM35, the temperature can be measured more accurately than with a thermistor. It also possess low self-heating and does not cause more than 0.1 °C temperature rise in still air. The operating temperature range is from -55°C to 150°C. The LM35's low output impedance, linear output, and precise inherent calibration make interfacing to readout or control circuitry especially easy. It has found its applications on power supplies, battery management, appliances, etc.

The LM35 is an integrated circuit sensor that can be used to measure temperature with an electrical output proportional to the temperature (in °C). It can measure temperature more accurately than using a thermistor. The sensor circuitry is sealed and not subject to oxidation. The LM35 generates a higher output voltage than

thermocouples and may not require that the output voltage be amplified. The LM35 has an output voltage that is proportional to the Celsius temperature. The scale factor is $.01\text{V}/^{\circ}\text{C}$.

Fig 3: Temperature Sensor

Humidity Sensor

Humidity is the presence of water in air. The amount of water vapor in air can affect human comfort as well as many manufacturing processes in industries. The presence of water vapor also influences various physical, chemical, and biological processes. Humidity measurement in industries is critical because it may affect the business cost of the product and the health and safety of the personnel. Hence, humidity sensing is very important, especially in the control systems for industrial processes and human comfort.

Fig 4: Humidity Sensor

Controlling or monitoring humidity is of paramount importance in many industrial & domestic applications. In semiconductor industry, humidity or moisture levels needs to be properly controlled & monitored during wafer processing. In medical applications, humidity control is required for respiratory equipments, sterilizers, incubators, pharmaceutical processing, and biological products.

Humidity control is also necessary in chemical gas purification, dryers, ovens, film desiccation, paper and textile production, and food processing. In agriculture, measurement of humidity is important for plantation protection (dew prevention), soil moisture monitoring, etc. For domestic applications, humidity control is required for living environment in buildings, cooking control for microwave ovens, etc. In all such applications and many others, humidity sensors are employed to provide an indication of the moisture levels in the environment.

LCD (Liquid Crystal Display)

An LCD (Liquid Crystal Display) is a widely used technology for visual output in electronic devices. LCD displays consist of a layer of liquid crystals sandwiched between two layers of glass or plastic, with electrodes at each end. The liquid crystals have the unique property of being able to modulate the passage of light when an electric current is applied. This modulation is precisely controlled to produce the desired images or text.

Fig 5: LCD Display

LCDs are known for their lightweight, thin form factor, and low power consumption, making them ideal for a broad range of applications, from consumer electronics like smartphones, tablets, and televisions, to industrial equipment and instrumentation. The displays can be either monochrome or color, and advancements in technology have led to the development of various types, including TFT (Thin-Film Transistor) and OLED (Organic Light-Emitting Diode) displays. LCDs offer high-resolution visuals, excellent contrast ratios, and a wide viewing angle, contributing to their widespread adoption in modern electronic devices.

Software Description

Arduino Software (Ide)

A software platform called the Arduino Integrated Development Environment (IDE) is used to program and create applications for Arduino microcontrollers. With an intuitive interface, the IDE offers code editor, compiler, and uploader features that make it simple for users to write, build, and upload code to Arduino boards. The IDE makes it easier to create interactive projects by supporting a streamlined version of C/C++ and providing a built-in library manager that makes it simple to integrate pre-written code modules.

EXPERIMENTAL RESULTS

Results

The experimental results demonstrate the significant advantages of utilizing innovative IoT technologies coupled with artificial intelligence (AI) in greenhouse farming. Through the integration of non-image IoT devices, our scalable intelligent system effectively monitors and controls greenhouse climatic conditions, reducing energy consumption while optimizing productivity. Unlike traditional methods that rely on manual labor for disease detection, our approach enables efficient and real-time detection of plant diseases by automatically analyzing non-image data generated by agriculture sensors. This method not only streamlines the disease

detection process but also minimizes the need for extensive human intervention. Furthermore, treating the AI model as an IoT device allows for seamless management alongside other IoT devices, significantly reducing platform management costs while providing timely training and predictions. By employing model transformations and a model-driven architecture, we successfully organize diverse raw data formats into a unified and technology-independent structure, further enhancing the system's efficiency and effectiveness in improving agricultural production.

CONCLUSION

In order to overcome the very restrictive climatic conditions in the greenhouse environment, a highly scalable intelligent system that monitors the greenhouse environment, generates the reference temperature, and regulates the internal temperature was developed. The use of a PN model allows us to monitor the greenhouse environment, to generate suitable reference temperatures, and to supervise the whole system. The proposed that utilize non-image IoT devices to detect fertilizers and temperature recommendations. In our approach, the agriculture sensors generating non-image data can be automatically trained and analyzed by the AI mechanism in real time. The beauty of proposed is that the AI model is treated as an IoT device and therefore can be managed like other IoT devices.

LITERATURE REVIEW

Exploring driverless metro train technology for student understanding the created nations like Germany, France, and Japan. At whatever point the prepare touches base at the station its tops naturally, as detected by an IRsensor. At that point the entry way is opens consequently so that the travelers can go inside the prepare. The entry way then closes after an end or set time set in the controller by the program. This implanted application mainly focuses on overcoming escape clauses in the current framework. The project is designed to keep costs low and use power efficiently

This train is equipped with a controller that enables the automatic stopping of the train from station to station. This paper presents the development process of a prototype for a autonomous train implemented using a peripheral interface controller tiny-controller. Simulation for the system's circuits is done with the aid of Proteus software. The hardware circuits, which are built on printed circuit boards Peripheral interface controller are interfaced with actuators and sensors for automation purposes. The hardware is assembled in a miniature model prototype train. The C programming language is used for programming the tiny-controller.

The paper introduces a metro traffic model that into consideration the energy consumed Thereby, Dual Heuristic Dynamic Programming technique is helps optimize how automated train system are designed it does this by using simulation to understand how much energy the system will used and testing those designs with real data from field this approach ensures that the ATS designs is both energy efficient and reliable under real world conditions Results show that designing the automated train system ATS with energy saving features using the DHP method is

feasible In addition, traffic regulation with better energy efficiency is attainable with the ATR design through coasting and dwell time control.

Automatic train regulation dominates the service quality, transport capacity, and energy usage of a metro-line operation. The train consumption of a metro line, and devises an adaptive-optimal-control algorithm to optimize the train regulator through reinforcement learning. In reinforcement learning, updating rules are basic steps that teach the system to get better by adjusting how it make decisions testing with field traffic data for optimization

This paper shows the form of the optimal solution and how to minimize enery of the train driving control that can be included into Automatic Train Operation systems. In this situation we looking at a train running automatically on a track with ups and downs that aren't constant all while following speed rules using the genetic algorithms (GA), we constructed optimal train driving strategy. The results are compared with P. Howett's the optimization method using the constrained optimal technique (Lagrange Function & Kuhn-Tucker equations) in view of energy cost benefit.

PROPOSED SYSTEM

For the existing system not accuracy to automatic train moving so go for our proposed system of "SMART CROWD MANAGEMENT IN METRO TRAINS WITH IR TECHNOLOGY" So added the new technique In our project we employed a new technique for plc microcontroller are used our system because pic microcontroller are accuracy and low cost can easily have implemented and easily used.

- Advantages of proposed system
- Accessible transit solution for remote locations
- Fully air conditioning trains.
- By using the automatic train systems, we can travel a safe journey.
- High speed technology

- Modernity
- Accessibility
- Ease of Use
- Selecting a Template (Heading 2)

Maintaining the Integrity of the Specifications

The template control your papers formatting such as margins column widths line spacing and font styles stick to these setting to ensure consistency and comply with style guidelines You may note peculiarities. For example, the template’s large head margin is intentional and suits its role within broader proceedings context

The IR LED-photodiode arrangement is placed such that both are placed parallel to each other. The photodiode doesn’t get the light pulses; result the microcontroller will get a high signal. The IR LED gets reflected by any object (suppose the station signal), Result the microcontroller will get a low signal.

The tiny-controller also sends a high signal to the door motor driver such that it drives the motor to open the door. The time end the tiny-controller sends a low signal to the door motor driver such that it drives the motor to close the door.

The IR LED-photodiode arrangement, when a person entre the door, there is interrupt between the IR LED and the photodiode send a logic high signal to tiny-controller. When the person leaves the door, there is interrupt between the IR LED and the photodiode send a logic low signal to tiny-controller.

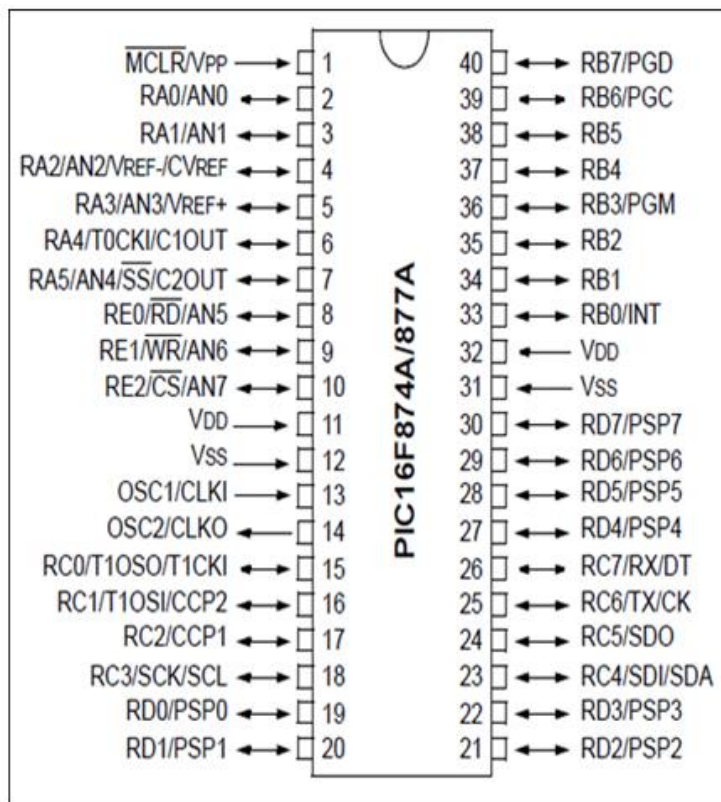

HARDWARE DESCRIPTION

General Requirement

The requirement for the project automatic moving train with help of IR sensor and passenger counting systems also. The specification of each and every requirement is mentioned below.

Pic microcontroller

Here we used PIC16fxx40 pin for performing multi functions within same pin. The microcontroller sends the data to PC through MAX232. The data is sent to the PC periodically for a set time duration. The PC thus sends the information to the GSM using MAX232 further it is sent to mobile through message. The PIC microcontroller is popular among industries and other purposes because of the availability of microcontrollers at low cost and small circuits.

DISTANCE MEASURING FOR IR

This circuit is consisting of the two IR sensor one for front side and another one for back side of the train. For forward and reverse in same signal direction. And IR sensor using the passenger counting systems interrupt between the entry and leaving.

Software Description

For IR based metro train, we had developed the program using MICROSOFT C and used dot net and visual studio for displaying the control parameters. The simulation of our project was done with the help of PROTIUS software.

CONCLUSION

Nowadays the accidents of trains are increasing day by day. Of these major accidents often occur due to human errors a man can do a mistake but a programmed processor doesn't have a chance of doing error. This project aims to improve metro train operations by effectively managing crowds this is a highly advanced technology which is currently used in developed nations such as Japan, Germany, and France etc. By using this auto metro train, the timings of the train will be exact and it avoids a lot of inconvenience to the passengers. This project will greatly reduce the human intervention in the control of trains and hence saves a lot of time and money. The project "SMART CROWD MANAGEMENT IN METRO TRAINS WITH IR TECHNOLOGY" aim to reduce human intervention in train control saving time and money

ABSTRACT

The number of electric vehicles has increased dramatically in recent years. (EVs) on the road, comprising fuel-cell electric vehicles (FCEV), Plug-in hybrid Electric Vehicles (PHEVs), Hybrid Electric vehicles (HEV), and Battery-Electric Vehicles (BEV). Based on current trends, it is anticipated that internal combustion engine (ICE) cars would eventually be replaced by this means of transportation. Every essential EV Component combines a number of Technologies that are either in use right now or could gain popularity in the future. Electric vehicles (EVs) have the potential to negatively impact the environment, power networks, and various other businesses. Although there is a risk of severe power systems instability if EV adoption increases, EVs can play a major Role in the success of the smart grid idea if they are managed and coordinated properly. Additionally, EVs Have the Ability to drastically reduce.

INTRODUCTION

Electric vehicles, or EVs, have recently become more popular for a variety of reasons. The major responsibility is to reduce greenhouse gas emissions. The transportation industry accounted for 25% of greenhouse gas emissions from energy-

related industries, according to a 2009 study [1]. This figure is expected to fall as EVs become more widely utilized in the transportation industry, but there are additional reasons to revive this century-old, once-dead concept as a marketable and accessible commodity. Unlike traditional cars, which are extremely expensive to fuel, an electric vehicle (EV) is both quiet and simple to use. It's a great form of transportation in cities. In idle mode, it may start and stop rapidly, providing the complete torque directly from.

The concept of using electric motors (EMs) emerged shortly after the discovery of the motor. In automobiles was initially proposed. Electric vehicles (EVs) made up In the late 1890s, they accounted for 28% of all autos, and they were usually preferred to conventional internal combustion engine (ICE) cars [1]. However, with little oil costs, internal combustion engines (ICEs) quickly gained enormous speed, dominated the market, and advanced significantly. Despite being ignored, EVs had a chance to come back thanks to General Motors' 1996 introduction of the EV1 concept. Not too long after, other well-known automakers including Ford, Toyota, and Honda introduced their own electric vehicles. The first HEV to be commercially successful was Toyota's Prius. In 1997, it was made available in Asia [1]. Except for the Toyota Prius, which is still produced, these EVs are essentially nonexistent now.

TYPES OF EVS

The main kind of EV is capable of operating only on electricity, utilizing batteries as its only energy source. Alternatively, they could cooperate with an ICE representative. They are able to make use of different energy sources, nevertheless. Vehicles that are hybrid electric are known as HEVs. Technical Committee 69 of the International Electro technical Commission on Electric Road Vehicles (ERV) defines a hybrid energy vehicle (HEV) as a vehicle having multiple energy sources, storage, or converters, at least one of which is electrical energy [6]. This specification permits a wide range of HEV configurations. Because of this, each kind of combination has a specific name that is known to both specialists and the general public: Ultra-capacitor

(UC) assisted electric vehicles (EVs) are cars that have both a capacitor and a battery. FCEVs are vehicles that combine a fuel cell and a battery [2], [3],

Figure 1. Structure of a BEV, the inverter changes DC electricity to AC power [7]

Battery-electric vehicle

An inverter converts DC electricity to AC power, as seen in Figure 1 of a BEV [7]. Batteries are the only energy source used by BEVs to power their power train.. Range is therefore reliant on battery capacity. A typical charge lasts between 100 and 250 kilometers [7]. In actuality, a number many variables, including driving style, road conditions, climate, car layouts, battery type, and vehicle age, have historically been connected. When the battery's energy gets low, it may take up to 36 hours to fully charge it [8, 9]., which is a lot longer than fuelling an ordinary internal combustion engine vehicle. While there are several kinds that take much less time, none are as efficient as filling up a car. BEVs have a few benefits, like being convenient, easy to use, and having a straightforward design. They are environmentally friendly, noiseless, and do not release greenhouse gases. The use of electric propulsion can provide

Hybrid or Electric Car

An Electrical power Train (PT) and an internal combustion engine (ICE) work together to propel HEVs. This combination can take on various forms, which will be covered in the discussion that follows. When there is little demand for power, HEVs employ an electric propulsion mechanism. This is a huge benefit for things like city transit, as it uses less fuel when it's idle (like in traffic) and produces less

environmental emissions. The vehicle shifts to the ICE when a higher speed is required. These two drive trains can also cooperate to improve performance. Vehicles with turbochargers, like the Acura NSX, frequently use hybrid power systems to reduce turbo lag.

Regenerative braking or The Internal combustion engine can be used to charge the power sources. Consequently, for improved fuel efficiency, ICE-powered cars can now include an electrical propulsion system to become hybrid electric vehicles, or HEVs. These benefits have led to automakers have widely approved HEV layouts. A basic HEV's energy flows are shown in Figure 2. The ICE may use the motor as a generator to produce and store electricity in the battery, as shown in Figures 2(a) and 2(b). when the vehicle is starting. It is necessary to accelerate the car upon passing because the PT is driven by both the electric motor (EM) and the ICE. In order to recharge the battery and perform regenerative braking, the PT converts the motor into a generator while it is in motion. When cruising, the ICE turns into a generator and produces power.

Fuel-cell electric vehicle

Fuel cell electric vehicles, or FCEVs for short, are electric vehicles powered by chemical reactions in fuel cells. Since hydrogen is the fuel that is most frequently used in this industry, hydrogen fuel cell cars, sometimes known as FCEVs, are used. Transporting hydrogen requires the use of specialized high-pressure tanks. Oxygen is also derived from ambient air and is required for the creation of energy. Fuel cells provide energy to the EM, which utilizes it to drive the wheels. The extra energy is stored in a battery or super capacitor. [2, 3, 18]. Many FCEVs that are sold commercially, including the Honda Clarity and the Toyota Mirai, require batteries. Water is produced by FCEVs through the vehicle's tailpipes after being generated during the power-generating process. Figure 4 shows.

Figure 4. FCEV's configuration

Figure 5 shows the advanced features ratio between BEV and FCEV for 320 km (blue) against 480 km (green).

Assuming a typical grid mix in the US from 2010 to 2020 and that all hydrogen is delivered from natural gas, Figure 5 shows the advanced features ratio between BEV and FCEV for 320 km (blue) against 480 km (green). Amounts above 1 imply an advantage for FCEVs over BEVs.

EV CONFIGURATIONS

Because they lack the complex mechanical configurations required to power a normal car, EVs are very flexible. The motor is the only moving component in an electric vehicle. There are numerous ways to supply the motor with the necessary power. The power source and motor may be connected by electrical wires that are installed in various locations throughout the car. Furthermore, as previously noted, EVs have the option of operating only on electricity or in combination with both an

EM and an ICE. The versatility in EC setup has allowed for many setups depending on the kind of vehicle. An electric vehicle commonly has three subsystems. The energy supply, the auxiliary subsystem, and the propulsion subsystem.

HEV setups

Both an electric and an internal combustion engine power HEVs. Based on how they are configured, various configurations are divided into four groups [6]. Series hybrid configuration.

Hybrid structure of series

The setup of a parallel-hybrid

The setup of a series-parallel-hybrid

Robust hybrid arrangement

With a HEV, this is the easiest design to understand because the wheels are just linked to the motor. The engine powers a generator that generates electricity. This is essentially an EV with an ICE generator, to put it simply [6]. The series hybrid's powertrain design is seen in Figure 9. Table 2.

Parallel-hybrid arrangement

This arrangement links the ice & EM to wheels simultaneously. They can all supply power. As a result, it is an ICE car with electric assistance [6]. In this type of car, the EM can charge the energy storage using either regenerative braking or the ICE.

Figure 9 shows the drive train of a series hybrid system.

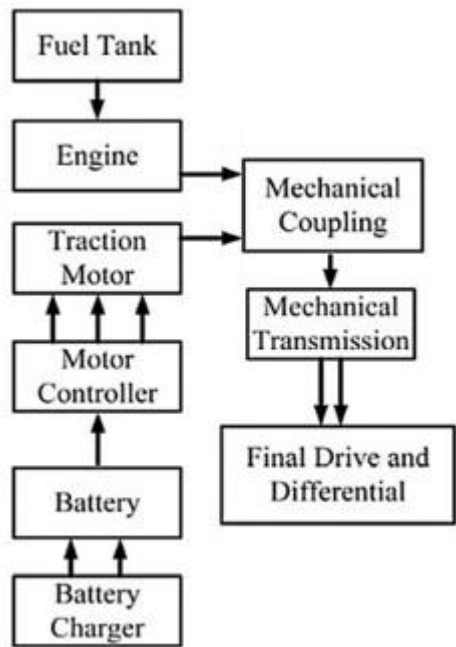

Figure 10 shows the PHEV system's driving train.

Series-parallel-hybrid configuration

The series-parallel-hybrid electric vehicle system both the series-hybrid and parallel hybrid topologies. (SPHEV). This method is more expensive and time-consuming, but it promises to offer the advantages of both. A planetary gear unit is partially to blame for the issues. Figure 11 shows the configuration of a planetary gear unit. The planetary carrier is connected to the internal combustion engine (ICE), the sun gear is connected to the generator, and the ring gear is linked to the output shaft and the pinion gears maintain the connection throughout the system. The transmotor is a simpler form in which the rotor is tied to the drive train wheel via gears and the engine is connected to the stator. How to set up a series-parallel hybrid drivetrain.

Figure 11: Planetary Gear Unit

Complex hybrid configuration

Bidirectional power flow is possible in the complicated hybrid system, in contrast to the series- Parallel architecture. According to current terminology, this system has a series-parallel architecture. This system suffers from both high costs and complexity [6]. Continuously variable transmission (CVT) can aid in power splitting and wheel propulsion source selection in complex hybrid systems. Toyota Motor Corporation has introduced the e-CVT, or electric-controlled variable valve technology, for these procedures. Hydraulic, mechanical, hydro mechanical, and electromechanical CVTs are only a few of the applications for CVTs. They can also be used for power splitting, with two possible approaches being input splitting or

complex splitting. For input splitting, a power-splitting mechanism is used at the transmission input. Specific Ford and Toyota vehicles.

ENERGY SOURCES

Depending on a few requirements, EVs can run on a variety of energy sources [6]. Energy density and power density are the two most significant of these. It is true that the ideal energy source would also need to have easy maintenance, low cost, extended service and cycle life, and quick charging. High specific power improves acceleration for short-distance driving. High specific energy is required for long-range travel. Many energy storage systems (ESS) are considered, with varied combinations to fulfill different purposes, source requires numerous features [6].

Battery

For a long time, batteries were the energy source for eventually, technologies were. Lead-acid, Ni-Cd, Ni-Zn, Ni-MH, Li-polymer, and Li-ion batteries of the types. The of graphene batteries for EVs, their structural models. Each type of battery has its own Table 5 the key of battery types.

CHARGING SYSTEMS

The part of AC charging systems is an AC-DC converter, which changes the AC supply into DC for charging. The Society of Automotive Engineers (SAE) has created the following categories for EV AC charging power levels:

Level 1: a maximum voltage 120 V and a current 12 A or 16 A, on circuit ratings, charging takes up to 12.5 hours, can be overnight EV.

Level 2: The most for electric (EVs) an EVSE with an on-board charger be connected .14.4 kW maximum power, 240V and maximum voltage, and 60 A maximum current.

CONCLUSION

In addition to having the ability to save the planet from the looming issues brought on by global warming, electric vehicles (EVs) have enormous potential to become the transportation of the future. They are a viable alternative to conventional cars, which are directly dependent on finite fossil fuel supplies. Numerous aspects of electric vehicles are covered in this page, such as their various configurations, power sources, charging techniques, and control schemes. The key technologies in each segment have been described along with their potential. Electric cars (EVs) have an immense potential to contribute to a cleaner and greener energy system through collaboration with smart grids and integration of renewable sources. The ramifications of EVs span several industries. The drawbacks of modern electric cars (EVs) have been noted, along with possible solutions. Additionally, the most recent optimization and control techniques have been included. Eventually, the article's conclusions synthesize the whole thing, providing a comprehensive picture of the EV industry as well as the areas that still need to be explored and researched further.

ABSTRACT

The project aims to simplify the electronic inspection process through an IoT-based system. The system uses the Internet of Things (IoT) to read and report energy meters, eliminating the need for manual meters. Key features include smart meters equipped with electronic sensors that use and transmit data wirelessly. A central hub collects this information and processes it for appropriate billing. Customers can access detailed information about their energy consumption through a special application by analysing the data in real time. The system increases efficiency by reducing human intervention, reducing invoice costs and ensuring timely payments. It also promotes sustainability by encouraging users to adopt energy-saving practices according to their consumption patterns. This new method not only simplifies the payment process, but also forms the basis for smart plans for greater energy management. The integration of IoT into energy costs increases the accuracy, accessibility and sustainability of the energy sector.

INTRODUCTION

Our project offers new solutions that will facilitate the payment of energy bills by focusing on the integration of IoT technologies to determine and report energy consumption. Smart meters are equipped with meters that will replace manual reading meters and recognize the time of data collection. These meters send usage data to a central hub via wireless communication, eliminating the need for manual intervention in the billing process. The aim of this project is not only to improve cost, but also to provide customers with a user interface through which they can track their energy consumption over time. This automation not only reduces human error, but also increases energy savings by providing users with

information about usage patterns. Using this IoT based approach we not only update the payment process but also improve the smart plan. The project is based on the principles of efficiency, accuracy and stability, providing future solutions to challenges in electric utilities.

EXISTING METHODOLOGY

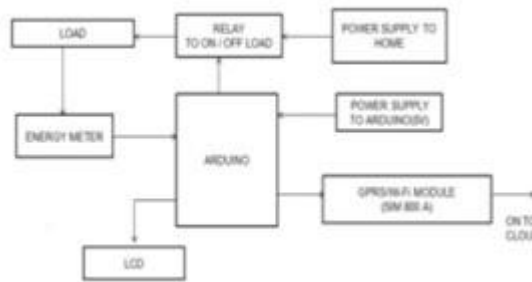

The current method of checking electricity bills using IoT is a technology that increases the efficiency and accuracy of the billing process. An important aspect of this approach is the deployment of smart meters equipped with IoT capabilities. Smart meters are simple devices that instantly measure and record energy use. These meters connect to the Internet of Things (IoT), allowing them to send customer data centrally.

In addition, the integration of IoT in this context allows energy companies to offer additional services to customers, such as real-time monitoring of energy consumption. Consumers can learn more about their energy consumption patterns through a mobile app or online portal, thereby increasing awareness and encouraging energy-saving behavior. In summary, the current approach to energy efficiency using IoT and smart meters is a change that increases accuracy, performance and customer engagement in electricity payment.

PROPOSED METHODOLOGY

The plan to control electricity bills using IoT involves the use of technology to improve the efficiency and accuracy of the billing process. With this new method, it is still important to deploy smart meters with IoT capabilities. Smart meters equipped with IoT sensors can monitor energy consumption in real time. These devices communicate seamlessly with central systems through IoT connectivity, facilitating continuous communication of customer data.

Moreover, the proposed method is to satisfy a set of requirements. Energy providers can use dynamic pricing models with real-time data on energy consumption or encourage customers to adjust their usage during peak times so that all grids are stable and working well. To further involve users, the system can provide users with a user-friendly interface such as a mobile application or online portal.

Arduino UNO

Arduino is an open platform for developing electronic tasks. Arduino consists of a physical programmable circuit board (often called a microcontroller) and software program or IDE (integrated development environment) that runs on the computer and is used to put in writing pc code and cargo it onto the physical board. The Arduino platform may be very famous amongst electronics beginners, and for true reason. In contrast to most programmable circuit forums of the beyond, the Arduino does no longer require a separate tool (referred to as a programmer) to write down new code to the board; You simply use one USB cable. Additionally, the Arduino IDE uses a simplified model of C++, which makes studying programming easier. Ultimately, Arduino has a prototype that expands the abilities of the microcontroller-based bundle

BD139 TRANSISTOR

A widely used NPN bipolar junction transistor, BD139, is utilized in the audio range. It is composed of three parts: the emitter, base, and collector. It has heavily doped the donor and lightly doped the base. The collector exhibits a slight increase in resistivity. A small current passing through the base of the transistor causes a larger current to be produced between the emitter and collector regions. The active region of the transistor results in a base-emitter junction being forward-biased (with 0.7V) and reverse-biased in the base-collector junction. This is an example of this phenomenon. Both emitter and collector currents in the active region are proportional. In the absence of current through the base, the collector current is zero in the cutoff region. On the flip side, the saturation region is defined as the area where the supply current is at its highest.

16×2 LCD DISPLAY

The 16x2 LCD layout permits the display of up to 16 characters per line, with 2 lines being equivalent. Each character on this LCD is presented in a matrix of 5x7 pixels. This displays 224 different characters and symbols on an intelligent alphanumeric dot matrix of 16x2. What is the trick here. The LCD is referred to as either commands or data. Digital watches, calculators and other electronic devices commonly incorporate a liquid crystal display (LCD) panel. Using liquid crystal, it produces images or text. Various sizes are available and they can display text in different colors. The screen can be displayed with a backlight, and the device can also be controlled through an Arduino or other microcontroller.

Node MCU

IoT systems are composed of sensors and devices that communicate with the cloud through a connection. Once the data is uploaded to a cloud, the software runs itself and can make decisions like updating the sensor or sending alerts. Framework. IoT user module hardware is responsible for connecting devices. Use the internet and communicate with other devices, sensors, and servers. By incorporating the ESP8266 Wi Fi module into the Node MCU firmware, Nodes Mcu is designed to function as a multi-tasking IoT development platform. Integrated with the microcontroller and Wi Fi chip, the Node MCU uses an embedded ESP8266 module for wireless connectivity. The Node MCU firmware eliminates complexity and offers a user-friendly API for programming through Lua scripts or the Arduino IDE. The ability of Node MCUs to connect to Wi Fi networks, use the Internet, and communicate wirelessly makes them a valuable addition to IoT applications. By using GPIO pins, it becomes effortless to control external devices like sensors or actuators. By using Node MCUs, developers can quickly and easily develop Wi-Fi applications and IoT solutions through programming in Lua or Arduino.

DC MOTOR

A 12V DC motor is a generator designed to perform on 12 volts direct modern-day (DC) energy. Motors encompass rotors, stators and commutators, brushed automobiles, and brushless cars. Brushed cars use brushes and a commutator to reverse contemporary float, even as brushless vehicles use alternating modern-day for efficiency. These cars are flexible and can be used in automobile structures together with windshield wiper cars, robots, power gear and small appliances. Unique design affects overall performance including torque and velocity. Mainly brushless 12V DC motors are frequently favored and boom performance by way of lowering the variety of brushes. Motor choice relies upon at the specific wishes of the utility, which includes traits which include energy intake, length and performance. All forms of DC motors work on the equal principle of electromagnetic induction. In line with this theory, whilst a conductor wearing electric contemporary is affected by a magnetic field, a pressure acts on the conductor. In step with the equal principle, 12v DC motor can use the magnetic area to start the DC motor and convert electricity into the motor. The present day within the motor coil creates a magnetic subject that interacts with the static magnet. This interaction creates a rotating force that reasons the engine to start.

12V DC ADAPTOR

The 12V power deliver (or 12VDC power supply) is one of the most broadly used strength supplies nowadays. Commonly 12VDC output is received from 120VAC or 240VAC input the use of a combination of transformers, diodes and transistors. Those gadgets paintings by means of the use of pulse width modulation to control the output voltage even as various

the frequency. Additionally replacing the digital manage unit will result in an excessive amount of EMI filtering. The working precept of the 12V DC adapter is based on the principle of strength conversion and transformation. While plugged into an outlet, it attracts present day (AC) from the strength supply. The first a part of the adapter is the transformer, which plays an vital function in decreasing the voltage. This process entails magnetic induction, in which the magnetic field modifications to create a magnetic discipline within the transformer, creating a low-voltage alternating modern. A rectification degree then converts the low-voltage alternating modern-day into direct present day (DC). Reconversion entails the usage of diodes to make sure modern flows in most effective one course, resulting in a DC waveform. Filter out capacitors are used to reduce flicker and provide a stable 12V output. The final level functions a voltage regulator that provides a constant 12V output irrespective of whether the electricity changes or changes. This is commonly executed the usage of a generator (consisting of a generator) or an included circuit designed for this motive.

THINGSPEAK

Thing Speak is an IoT analytics platform that allows users to collect data from connected devices and analyze the data using MATLAB-based analytics. The platform provides easy-to-use tools and integrations with other services to help users build IoT applications, visualize and analyze data, and perform tasks. It also provides instant data processing, text and email alerts, and allows users to take action on changes in data. Thing Speak's open API

and support for more than 400 IoT devices make it a popular choice among developers and enthusiasts looking to develop IoT applications and explore the potential of connected devices.

RESULT AND DISCUSSION

An energy efficiency research project leveraging IoT achieves better results, greater transparency and efficiency. Integration of IoT-enabled smart meters facilitates instant and accurate data collection, while machine learning algorithms reduce inconsistencies by improving the accuracy of energy consumption models. Business efficiency is increased by streamlining the billing process, reducing reliance on manual reading, and using cloud computing with increased capabilities. Integration of demand response systems enables dynamic pricing models that optimize grid control during peak periods. Customer engagement thrives through a userfriendly interface that allows for real-time monitoring and personalized recommendations. The initiative demonstrates cost-effectiveness by reducing manual processes and demonstrates its development in the electronics market by demonstrating the potential of future developments in IoT technology and energy efficiency applications.

CONCLUSION

The proposal to use EB bill control system using IoT has reached its potential to provide an efficient and easy way to monitor energy consumption and payment. The system uses an Arduino Uno board to control current and voltage measurements and then wirelessly sends them to a cloudbased server for processing. The system has been tested and validated and

the results have been shown to correlate with actual EB values. The system also provides users with a web-based interface to view historical data, track real-time usage, and receive notifications of bill charges. Based on user feedback and test results, it can be concluded that this application has the potential to be a useful tool that can help eligible families and partners improve energy use and save money. However, further development and modifications are required to make the system complete and more adaptable to different types of users.

ABSTRACT

This paper introduces an advanced control methodology for a Z-source virtual synchronous generator deployed in photovoltaic systems, employing a fuzzy logic controller (FLC). The ZVSG emerges as a promising solution for seamless grid integration of PV systems, ensuring stability and adaptability in power generation. The proposed control strategy facilitates diverse operational modes, including grid-connected, standalone, and islanded modes, all while maintaining consistent voltage and frequency outputs. Through the incorporation of FLC, controlling and regulating the DC-link voltage of ZVSG switching frequency are optimized, resulting in enhanced performance characterized through quick and agile responsiveness and minimized residual error over time. The simulation results confirm the effectiveness of the suggested control method in different operating modes and under fluctuating load conditions, highlighting its potential for improving ZVSG performance in practical PV applications.

KEYWORDS

Photovoltaic (PV) systems, virtual synchronous generators, impedance-source inverters, and low-voltage systems ride through.

INTRODUCTION

In recent years, Distributed generators (DGs) utilizing power electronics have been incorporated into contemporary power grids to enhance both their reliability and operational efficiency [1]. Consequently, the dynamic characteristics of the power grid are

undergoing swift transformations. For instance, the grid experiences a decline in voltage stability, oscillation mitigation, and inertial properties [2],[3]. The absence of rotating masses and kinetic energy in the power electronics interfaces used in DGs lowers the power grid's inertia constant [4]. By using a fuzzy logic controller (FLC) to enhance performance and flexibility, this research investigates the idea of an enhanced the system is designed to operate in multiple modes and is controlled by a Z-Source Virtual Synchronous Generator (VSG). Direct current (DC) produced by solar panels is normally converted into alternating current (AC) by inverters in photovoltaic systems so that it can be integrated into the grid. The stability and dependability of the grid are nevertheless threatened by the sporadic nature of solar radiation and fluctuations in load demand. With its special benefits over traditional inverters, the Z-Source VSG technology stands out in this regard as promising. Because of its versatility in accommodating different operational conditions, the Z-Source network is able to manage both voltage buck and boost operations. Since the energy output of PV systems is unpredictable, this built-in functionality makes it ideal for those systems. Photovoltaic (PV) systems can improve grid stability with a virtual synchronous generator (VSG).

While VSG control proves effective in addressing frequency-related contingencies within the power grid, it remains imperative to consider additional protective control schemes to fortify the grid against voltage-related contingencies [9]. Because of its multimodal operation design, the Z-Source VSG can switch Numerous research endeavours have concentrated on the operation of LVRT mode for PV panels connected to the network [10], [12], [13]. To improve energy harvesting efficiency and grid stability, the FLC modifies control settings in real-time based on inputs including solar irradiation, load demand, and grid condition. With a robust solution that can be used in a range of situations, such as off-grid electricity and urban solar systems, the strategy seeks to address issues in PV integration. In order to increase overall system performance, the study highlights how well fuzzy logic control works in conjunction with the special powers of the Z-Source network [15]. To validate the suggested approach, the next sections will examine the modelling, simulation results, and theoretical underpinnings.

LITERATURE SURVEY

Q. Jiang, H. Su, H. Lin, Q. He, H. Zeng, and Y. Che offer an effective approach for secondary frequency control (SFC) in virtual synchronous generators, stressing expected rotor frequency characteristics. Their approach streamlines parameter calculations by elucidating the interplay between rotor inertia, damping coefficient, integration coefficient, and low-pass filter time constant derived from simulation findings. In response, K. Shi. Song, H. Ge, P. Xu, Y. Yang, and F. Blaabjerg address challenges related to distributed power synchronous generators (SGs) and VSGs. Their investigation delves into the transient behavior of microgrids incorporating parallel VSG and SG systems. They propose a pre-synchronization control method to mitigate phase discrepancies, considering the power ratio of VSGs and SGs. Additionally, they suggest an active power supply strategy to dampen power transients, validating these techniques through simulation.

O'Donnell and J. Chen advocate for employing VSG control of converters to emulate virtual inertia in energy generation and storage facilitated by power electronics. Their study underscores the constraints of virtual inertia and damping parameters, emphasizing stability issues concerning converter and line dynamics. They underscore the damping-to-virtual-inertia ratio as a crucial parameter for VSG stability and reliability, approximating the system's behavior as second-order. This analysis quantifies the stability thresholds of VSG parameters and verifies them through comprehensive simulations of transition models, encompassing both stable and unstable scenarios.

FUZZY LOGIC CONTROLLER

Fuzzy logic, a sophisticated mathematical approach, excels in addressing complex simulated problems with numerous input and output variables. Distinguished from Boolean algebra, it provides recommendations within specific output intervals. In contemporary control systems, mathematical models often face challenges in transitioning from problem formulation to accurate representation. Fuzzy logic simplifies this complexity by incorporating tolerance for imprecision, vagueness, and uncertainty during modelling. This approach, capable of handling imperfect information, mirrors human decision-making, offering a faster alternative. Utilizing

measurements or assessments, fuzzy logic processes inputs through human-like "if-then" rules, combining them with traditional processing. The averaged results form a precise output decision, facilitating effective control in various systems.

Typically, a fuzzy logic control system comprises the fundamental components outlined in Figure 2: The fuzzy rule matrix, fuzzy inference engine, fuzzy fuzzification interface, and fuzzy defuzzification interface. Each of these elements, in conjunction with fundamental fuzzy logic operations, will be elaborated on further below.

Fig 1: Fuzzy Logic Controller

1. Fuzzy Logic Operations: Here's about basic info about fuzzy logic. For a more detailed understanding, you can refer to [15] for a thorough explanation of fuzzy logic theory.

2. Universe of Discourse: It's a collection of all the different values that can be considered as inputs in a fuzzy system.

3. fuzzy Sets: A fuzzy set μ is like a rule that assigns a number between 0 and 1 to each item in the reference set X . In other words, $\mu(X)$ shows all the fuzzy sets for X .

$$\mu: X \rightarrow [0,1]$$

4. Membership Function: It's a picture or diagram that shows fuzzy sets, represented as $\mu F(x)$.

Fig a: VOLTAGE Error

Fig b: VOLTAGE change in error

Fig c: Reference CURRENT

Fuzzification Method

The fuzzy logic method involves fuzzifying input parameters using pre-defined membership functions, such as triangular, bell, trapezoidal, sinusoidal, and exponential shapes. The membership function's strength is decided by putting the input variable on the side-to-side axis and measuring how much it belongs. Each input has its own function, which matches a weight with its values and rules. Multiplying these weights together gives a fuzzy output response.

The FIS type is Mamdani if you see sinusoidal waveforms for input variables and triangular membership functions for output variables. This means that the Mamdani fuzzy logic system uses sinusoidal fuzzification for inputs and Mamdani-style triangular fuzzification for outputs.

Rule Matrix

In Mamdani-type fuzzy inference systems, a 5x5 rule matrix is a popular way to show things. Each row in this matrix represents a separate crisp set from the input variables, and each column shows a fuzzy set in the output variable. The rule matrix is a mechanism to define fuzzy sets and fuzzy operators using if-then statements. A basic if-then rule might say: If something is A, then something else is Z. Here, A represents the conditions that need to be true, and Z represents the outcomes that can be predicted. The fuzzy inference system uses a structured method to record and process complex relationships between inputs and outputs by setting linguistic rules within this matrix. This makes it easier to make decisions in a number of contexts, such as control systems and expert systems. The rule table is shown in below:

e/ce	NB	N	Z	P
NB	PB	PB	P	Z
N	P	P	Z	Z
Z	Z	Z	Z	Z
P	Z	Z	N	N
PB	N	N	N	NB

Inference Mechanisms:

The inference process helps translate information into a result using fuzzy logic. It mixes membership functions, logical operations, and if-then rules to do this. The two basic types of inference systems are Mamdani and Sugeno, which differ in how they determine outputs. In this case, we're using the Mamdani method. In the examples below, there are two fuzzy control rules described as follows: If x

corresponds to A1 and y corresponds to B1, then z corresponds to C1 according to Rule 1. Similarly, if x corresponds to A2 and y corresponds to B2, then z corresponds to C2 according to Rule 2. Thus, given x as x_0 and y as y_0 , z corresponds to C, where the activation levels of these rules, denoted as α_i (where $i = 1,2$), are determined by

$$\alpha_1 = A_1(x_0) \wedge B_1(y_0)$$

$$\alpha_2 = A_2(x_0) \wedge B_2(y_0)$$

The outputs of each rule individually are derived by

$$C'_1(\omega) = (\alpha_1 \wedge C_1(\omega))$$

$$C'_2(\omega) = (\alpha_2 \wedge C_2(\omega))$$

Next, the whole system's output is determined by organizing the individual rule outputs.

$$C(\omega) = C'_1(\omega) \vee C'_2(\omega) = (\alpha_1 \wedge C_1(\omega)) \vee (\alpha_2 \wedge C_2(\omega))$$

Defuzzification Method

The centroid defuzzification technique is favoured for its exceptional precision, as it computes the central point of the region bounded by the membership function curve. However, for complex membership functions, it requires a lot of computational effort. This method can be described using the below for

$$z_0 = \frac{\int \mu_i(x)xdx}{\int \mu_i(x)dx}$$

In the context of defuzzified output, where μ_i represents the membership function and x denotes the output variable, bisector defuzzification employs a vertical line to bisect the area under the curve, ensuring equal partitioning into two segments.

$$\int_{\alpha}^z \mu_A(x)dx = \int_z^{\beta} \mu_A(x)dx$$

The average value of the combined membership function findings is used as the mean of the maximal defuzzification approach.

$$z_0 = \frac{\int_{x'} x dx}{\int_{x'} dx}$$

Where $x' = \{x; \mu A(x) = \mu^*\}$. The smallest value of the combined membership function outputs is used by the smallest of the maximal defuzzification techniques.

$$z_0 \in \left\{ x \left| \mu(x) = \min_{\omega} \mu(\omega) \right. \right\}$$

The maximum defuzzification approach employs the largest value of the aggregated membership function outputs.

$$z_0 \in \left\{ x \left| \mu(x) = \max_{\omega} \mu(\omega) \right. \right\}$$

Based on the assigned fuzzy output's, the precise output value is determined by applying the subsequent formula:

$$z_0 = \frac{\sum \mu(x)_i \times W_i}{\sum \mu(x)_i}$$

Where W_i is the output singleton's fuzzy output weight value, and μ_i is the degree to which the output singleton is a member of the set.

PROPOSED METHOD

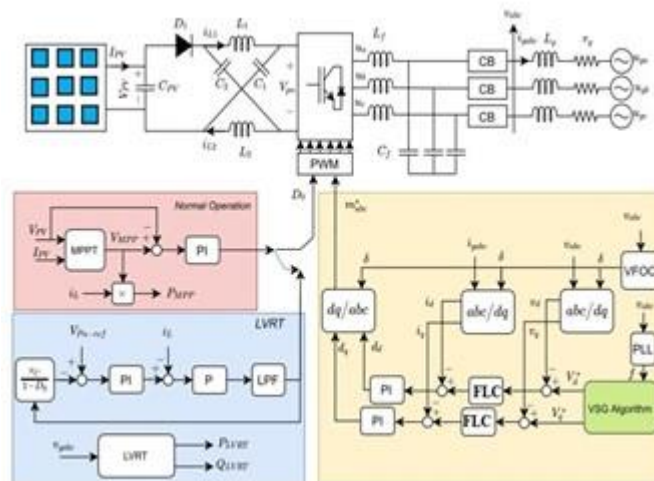

Fig 1. ZVSG converter with FLC controller-based VSG and LVRT control algorithms.

The block diagram provides a complete description regarding the control system. At the centre of the system is the ZVSG, designed to work fluidly across several modes, such as grid-connected, standalone, and islanded modes. The integration of FLC at specific nodes in the block diagram, exhibiting the adaptability and precision of fuzzy logic in regulating the dc-link voltage and controlling the ZVSG shifted frequency. This change boosts the ZVSG's performance by ensuring a rapid and dynamic reaction, effectively lowering steady-state error. The innovative arrangement also features of MPPT and LVRT functionalities, exhibiting the versatility of the system in responding to various PV conditions and grid disturbances. Overall, the block diagram displays a smart and efficient control method, placing FLC as a valuable alternative to standard controllers in optimizing the operation of ZVSG in PV systems.

PRINCIPAL OPERATION OF ZSI

In ZSI, the occurrence of shoot-through states involves a momentary connection of the load terminals via both the upper and lower switches within any phase legs. Unlike traditional voltage source inverters, which would suffer damage and short the DC connection under such circumstances, ZSI switches are capable of exploiting all potential switching combinations, thus eliminating the necessity for dead time. Consequently, current distortion is minimized, leading to an expected decrease in the overall harmonic distortion of the current. Moreover, the Zero Sequence Injection (ZSI) provides an enhancement function through the manipulation of both the inverter's modulation index (m) and the duration of the shoot-through interval. The ZSI's output voltage (u_{abc}) is calculated using equation (1):

$$B = \frac{V_{pn}}{V_{PV}} \quad (1a)$$

$$u_{abc} = m^* B \frac{V_{PV}}{2} \quad (2b)$$

When discussing a balanced configuration where the values of inductors (L_1 & L_2) and capacitors (C_1 & C_2) remain equal, denoted as (2), in the context of boosting factor (B), input voltage from a DC source (V_{PV}), and output voltage from the impedance network (V_{pn}).

$$\begin{aligned} v_{C_1} &= v_{C_2} = v_C \\ i_{L_1} &= i_{L_2} = i_L \end{aligned} \quad (2)$$

Where i_L and v_C are the inductor current and impedance network capacitor voltage respectively. The relationship between the inputs and outputs of the ZSI is represented by the secondary voltage equation and the capacitor charge moderate equation for the inductor voltage and capacitor current, shown in (3):

$$V_{pn} = \frac{V_{PV}}{1 - 2D_0} = \frac{V_C}{1 - D_0} \quad (3a)$$

$$V_C = \frac{1 - D_0}{1 - 2D_0} V_{PV} \quad (3b)$$

The paper employs a simple boost modulation technique to control the shoot-through duty ratio, denoted as D_0 , where to guarantee a satisfactory margin for voltage control, D_0 must be in between to $(1 - m^*)$. $D'_0 = 1 - D_0$ represents the non-shoot-through duty ratio.

PROPOSED CONTROL MODES OF OPERATIONS

The ZVSG converter can be used in various situations because it is adaptable and versatile. Operating within the inverter, the Voltage-Source Generation (VSG) algorithm guarantees exact control and tracking of the rated frequency when the

photovoltaic (PV) system runs at the required frequency and voltage levels. Employing In this mode, Maximum Power Point Tracking functions as an active power setpoint for the VSG control, guaranteeing that the inverter sustains a power factor of unity. If there's a low-voltage fault, the system seamlessly switches to LVRT. In LVRT mode, the control system intelligently reduces active power while concurrently raising reactive power to rectify the voltage disturbance. Ensuring swift adaptation to low-voltage scenarios, the generation of fresh active and reactive power references adheres closely to grid regulations and system demands. This dynamic control strategy, facilitated by a fuzzy logic controller, empowers the ZVSG converter with exceptional responsiveness to diverse operational conditions and grid dynamics, thereby enhancing its efficacy and reliability across a spectrum of operational contexts.

DURING NORMAL CONDITION

1. DC Side Control: In the presence of a fuzzy logic controller (FLC), the DC side control, as displayed in Fig. 1, maintains MPPT for the PV array using the perturb and observe (P&O) algorithm. The FLC controller assesses the measured voltage (V_{pn}) in comparison to the voltage reference corresponding to the maximum power output point (V_{MPP}). The FLC dynamically changes the shoot-through duty (D_0), thereby regulating the voltage generated by the impedance network's output V_{pn} . This adaptive control strategy, driven by fuzzy logic decision-making, improves the precision and responsiveness of MPPT under varying environmental conditions. The FLC-based method optimizes the PV system's performance, ensuring efficient energy extraction and overall enhanced system efficiency.

2. AC Side Control: Integrating the conventional Synchronous Generator's mechanical equation into control loops of PV systems ensures stable performance during standard operation and frequency-related

occurrences. The Virtual Synchronous Generator algorithm functions through two stages: firstly, solving the swing equation of the SG via numerical methods to determine a reference angle, and subsequently utilizing this angle to produce a 3- ϕ ref voltage. Eqn (4) concisely outlines the mechanical equation of an SG.

$$\begin{aligned} \frac{d\theta}{dt} &= \omega \\ 2H \frac{d\omega}{dt} &= T_m - T_e - D_p \Delta\omega \end{aligned}$$

In the equation (5), H denotes the time constant of inertia, ω denotes the rotational frequency, and D_p represents the coefficient for power damping. T_e and T_m respectively denote the electromagnetic and mechanical torque output.

$$T_m = k_f(f_0 - f) + \frac{P_{ref}}{\omega} \quad (5a)$$

$$T_e = \frac{P_e}{\omega} \quad (5b)$$

The VSG algorithm calculates the reference voltage magnitude E_{ref} (6) based on measured P_e and reference P_{ref} , The generated active power from the photovoltaic (PV) system, coupled with the active power droop coefficient, dictates the system's performance k_f , and rated f_0 and measured (f) system frequencies.

$$E_{ref} = E_0 + E_Q \quad (6)$$

During the operation of normal mode, the ZVSG's reference voltage is calculated using the grid voltage amplitude E_0 , the reactive power adjustment E_Q is set to zero, the reference voltage is established based on \vec{E}_{ref} and the computed reference angle (θ) as shown in equation (7).

$$\vec{E}_{ref} = \begin{bmatrix} e_{ar} \\ e_{br} \\ e_{cr} \end{bmatrix} = \begin{bmatrix} E \sin(\omega t) \\ E \sin(\omega t - \frac{2\pi}{3}) \\ E \sin(\omega t + \frac{2\pi}{3}) \end{bmatrix} \quad (7)$$

Fig. 2 shows that the voltage will be used in Park transformation (8) to control the AC converter's voltage and current.

$$T_{abc/dq} = \frac{1}{\sqrt{3}} \begin{bmatrix} \cos(\delta) & \cos(\delta - \frac{2\pi}{3}) & \cos(\delta + \frac{2\pi}{3}) \\ -\sin(\delta) & -\sin(\delta - \frac{2\pi}{3}) & -\sin(\delta + \frac{2\pi}{3}) \end{bmatrix} \quad (8)$$

The ref voltage specified in equation (7) serves as a ref for the outer voltage loop, where the angle of input voltage is determined using the VFOC method [4]. The converter's voltage and current are regulated using traditional control loops.

In Figure 2, The ref voltage for the outer loop is created by combining the VSG reference angle θ with the reference voltage magnitude.

VIRTUAL FLUX OPERATIONAL CONTROL

The VSG control technique utilizes the grid's frequency and phase angle to establish the converter's operational position during synchronization. This is

achieved by employing a PLL (phase-locked loop) and monitoring the voltage of that grid v_{abc} , as outlined in equation (9). However, this method degrades under harmonic distortion. Virtual UX is proposed to accurately identify essential voltage components.

$$\psi_{abc} = \int v_{abc} \cdot dt. \quad (9)$$

This method eliminates harmonic distortion by using the integral calculation as a low-pass filter. A quadrature lag exists between flux ψ_{abc} and voltage v_{abc} when ψ_{abc} . The point where it crosses the d-axis of the (synchronous reference frame) SRF. To determine the Park transformation position angle, calculate the input angle in (10) after transforming ψ_{abc} to a reference frame using the

$$\delta = \tan^{-1} \frac{\psi_\beta}{\psi_\alpha}. \quad (10)$$

A low-pass filter can calculate the integral, but it can cause phase and magnitude mistakes for simple DC signals. Reducing the filter's cutoff frequency may partially alleviate the issue but may decrease bandwidth and impair dynamics. This research employs a rigorous virtual flux computation (11):

$$\begin{aligned} g_3(s) &= \frac{\psi(s)}{v(s)} = G_{BPF}(s) \cdot G_c(s) \\ &= \frac{K_B s}{s^2 + (\frac{wb}{Qb})s + w^2} \cdot \frac{1 + \tau s}{1 + \lambda \tau s} \end{aligned} \quad (11)$$

$G_{BPF}(s)$ is presented equation depicting the transfer function of the band-pass filter utilized for isolating the initial voltage harmonic. Simultaneously, $G_c(s)$ denotes lag compensation ($\lambda > 1$), which serves to maintain the perpendicular relationship between flux and voltage.

Figure 3 shows us the bode plots $g_1(s) = \frac{1}{s}$ low-pass filter $g_2(s) = \frac{1}{s + \omega_c}$, and $g_3(s)$ in (11) to assess the suggested method's performance. Since $g_3(s)$ has a smaller

amplitude than $g_1(s)$ and $g_2(s)$ near the operating point, it rejects disturbances better in that working region.

PRE-SYNCHRONIZATION OF THE GRID CONNECTION

The micro-grid receives frequency and voltage from DGs in islanded mode. However, this voltage reference may differ from the grid [1]. As previously discussed, the Park transformation is employed to convert voltage and current from the distributed generation (DG) system into the Synchronous Reference Frame (SRF) to meet control objectives. Figure 4, the control parameters undergo synchronized rotation at an identical angular velocity, yet there exists a potential phase misalignment between their d (or q) axes. This misalignment in phase could trigger an abrupt surge in current at the PCC when the Distributed Generators are right linked to the grid. Such an unforeseen surge in current has the potential to induce grid failure or instigate a sequence of unanticipated occurrences, including the activation of overcurrent protection relays.

Fig. 4. Comparison of angular difference between ZVSG (D/Q) and (d/q) the grid reference frames.

In order to obtain a single Synchronous Reference Frame (SRF) for all state variables, the paragraph explains the requirement for a pre-synchronization technique. This study employs voltage-frequency-oriented control (VFOC), depicted in Figure 5, to synchronize with the grid voltage phase and adjust the relative phase difference ($\Delta\theta$) between the grid and the ZVSG output voltage. After a 90° phase shift introduced by VFOC, the voltage's dq components become $v_d = 0, v_q = -1, v_0 = 0$. The position (δ) from VFOC serves as the phase angle input for the park transformation process. Subsequently, the relative phase angle is adjusted by the negative feedback controller ($\Delta\theta$). The calculated angular velocity (ω_p) is then integrated into the VSG algorithm control loop, as shown in Figure 6, to properly bias the VSG angle, θ .

DURING VOLTAGE SAG CONDITION

The proposed ZVSG is designed to function across various operational modes. Here, we elaborate on the method for restoring voltage following a grid fault. Upon fault detection, the control system of PV must decrease the output of active power. Failure to do so would lead to an excess of produced reactive power essential to restore voltage levels, potentially surpassing the converter current limit and escalating conservation expenses. To address this issue, the ZVSG must transition its controller mode from normal Maximum Power Point Tracking (MPPT) operation to

Low Voltage Ride Through (LVRT), necessitating adjustments to both the DC and AC side controls.

1. DC Side Control: During a fault condition, when the ZVSG is inactive in normal operation, another controller approach is necessary to manage the dc link voltage and determine the dead time duty cycle, D0. To address this requirement, a fuzzy logic controller (FLC) is employed within an indirect control framework to govern the power across the impedance system. The FLC operates by tracking the reference voltage (V_{pn-ref}) through an outer loop, employing a fuzzy logic-based approach for enhanced adaptability. At the same time, a secondary proportional loop, incorporating FLC, is utilized to monitor the inductor current (il). This two-tier FLC approach boosts current regulation during temporary occurrences, leading to enhanced stability margins across the entire system.

2. AC Side Control: During grid disturbances, the proposed fuzzy logic controller (FLC)-based control system enhances voltage stability by injecting reactive power into the grid. However, solely controlling reactive power injection may lead to exceeding the safe limit of grid current (IG), risking system damage or shutdown. To prevent this, the FLC-controlled system ensures stability during voltage faults by keeping the peak current amplitude within a safe range. When a grid voltage defect is detected, the system switches from MPPT to LVRT mode [5], reducing active power production while supplying the

necessary reactive power to restore voltage to normal levels. Using the FLC controller, the reactive power required to restore voltage (Q_{ref}) is calculated based on the grid voltage (vg).

$$\begin{cases} i_q = k(1 - vg)I_{rated} & (1 - \frac{1}{k}) \leq v_g \leq 0.9 \text{ p.u.} \\ I_{rated} = I_{gmax} \end{cases} \quad (13)$$

In this case, I_{gmax} the maximum current that the ZVSG can deliver to the grid during voltage failures is called I_{gmax} , and it is equal to the grid's rated current, or I_{rated} . Consideration is given to a dead band of 0.1 when voltages fall into the disturbance category rather than the fault category. Given that rated I stays constant, the necessary. I_{rated} can be computed as follows (14):

$$i_d = \sqrt{I_{rated}^2 - i_q^2}. \quad (14)$$

The direct power theory used to compute the active (P_{ref}) and reactive power (Q_{ref}) references during LVRT mode by computing the power components (i_d and i_q), as shown in (15):

$$\begin{bmatrix} P_{ref} \\ Q_{ref} \end{bmatrix} = \begin{bmatrix} v_d & v_q \\ v_q & -v_d \end{bmatrix} \begin{bmatrix} i_d \\ i_q \end{bmatrix} \quad (15)$$

As mentioned, d axis grid voltage v_d , is equal to zero, and simplified by [16].

$$\begin{cases} P_{ref} = v_q i_q \\ Q_{ref} = v_q i_d \end{cases} \quad (16)$$

The VSG algorithm incorporates the active power reference, denoted as P_{ref} , to ascertain the reference angle, θ . Although the voltage and current control loops within the VSG function akin to previous operations, there is a shift in the voltage reference methodology. This updated approach involves initially regulating reactive power, as specified in equation (17).

$$K \frac{dE_Q}{dt} = Q_{ref} - Q_e - D_q(v - V_{ref}) \quad (17)$$

where Q_e represents the observed reactive power of the system, V_{ref} is the rated amplitude of the grid voltage, E_Q stands for the reactive part of the voltage, and K

denote the inertia and D_q denotes droop coefficients. The equilibrium of a three-phase voltage can undergo a conversion to an analogous Synchronous Reference Frame (SRF) utilizing equation (7). The derivation of the fresh reference voltage employs equation (6) in conjunction with the specified reference angle θ , ensuring precise reference is crucial for the control loops of voltage and current.

The effectiveness of the suggested Multi-Mode Operation and Control system for a ZVSG in Photovoltaic Systems, employing a Fuzzy Logic Controller. The study explores various operational modes and assesses the control strategy's effectiveness under different conditions, such as normal operation, grid faults, and transitions between MPPT and LVRT modes. voltage stability, reactive power injection, and efficiency, are analyzed to validate the effectiveness of the proposed approach.

Selecting the right sampling time for each module depends on how complex the control algorithms are and achieving the desired performance. Therefore, the following criteria are taken into account to assess the performance of the ZVSG: Improving steady-state operation to maximize power harvesting, increasing frequency stability margins by improving the RoCoF of the system, and supplying reactive power during low voltage ride-through (LVRT) mode are key areas of focus.

The study explores various operational modes and assesses the control strategy's effectiveness under different conditions, such as normal operation, grid faults, and transitions between MPPT and LVRT modes. voltage stability, reactive power injection, and efficiency, are analyzed to validate the efficiency of the proposed approach.

Figure 7 depicts the inrush current observed when the Z-source VSG is being associated to the grid. The current waveform when the ZVSG is attached without any pre-synchronization control is displayed in Figure 7a. In contrast, Figure.7b illustrates After integrating the suggested pre-synchronization approach detailed in Section 6, the waveform displays a recognizable decrease in peak amplitude accompanied by a more gradual transition period, notably reducing the peak current transient by roughly 2200 amps

During the transition from normal operation to voltage sag condition state, the magnitude of the current for grid remains steady, ensuring that it does not surpass the over-current protection threshold. This is depicted in FIGURE 9, The depiction of the ZVSG's operational modes delineates (a) typical functioning, (c) the onset of a voltage sag at time t_1 prompting the transition to voltage sag condition, and (d) the resumption of normal operation at time t_2 .

CONCLUSION

In conclusion, this paper presents an innovative method to control a ZVSG in photovoltaic (PV) systems using a fuzzy logic controller (FLC). The ZVSG offers a promising solution for seamlessly integrating PV systems into the grid, ensuring stability and adaptability in power generation. The proposed control strategy enables versatile operation modes, including grid-connected, standalone, and islanded modes, while maintaining consistent voltage and frequency outputs.

The system's operational effectiveness was assessed during the shift from isolated operation to integration with the grid. To mitigate arrival current during grid connection, a pre-synchronization switch strategy is utilized to reduce the phase disparity between the grid and the converter. Moreover, an integrated measure is introduced to safeguard the system against voltage disturbances, enabling it to manage reactive power in accordance with grid regulations.

Thus, the control strategy shifts from MPPT to Low voltage mode upon detecting a decrease in system voltage. Under this method, the peak value of grid current is maintained constant during LVRT operation mode, thereby preventing surpassing the overcurrent protection threshold. The ZVSG integration into OPAL-RT digital simulator has proven effective, facilitating smooth transition between standard and faulty conditions, ensuring system operation.

ABSTRACT

Every year, our world is shaken by the destructive force of landslides, a menacing natural disaster that disrupts social life and leaves a trail of devastation in its wake. Picture a massive Pile of stones and fragments hurtling plummet a steep incline, causing havoc and destruction in its path. It's a sight that exemplifies the immense power of nature .Out of all the continents, Asia has suffered the most, bearing the brunt of 75% of all landslides worldwide. This vast and diverse continent has been marked by numerous incidents that have claimed lives and caused immeasurable damage. It's a somber reminder of the precariousness of our existence in the face of such natural phenomenon. India, a country blessed with breathtaking landscapes and rich biodiversity, has not been spared from the wrath of landslides .in kerala, throughout the monsoon period last year, the southern state of India, tragedy struck as landslides took a toll on human lives. The loss and devastation serve as a stark reminder of the importance of early detection and proactive measures to safeguard communities.

INTRODUCTION

Landslides, characterized by The downward motion of rocks, debris, or soil along a incline , pose a significant threat to our natural environment and human lives. During monsoons, rainwater seeps into the ground, creating hydraulic pressure that surpasses the soil or rocks' elastic limit. As a consequence, strain builds up, Provoking a diminution in the tenacity of soil and rocks, culminating in the onset of landslides. The devastating

consequences of landslides include the destruction of agricultural and forest lands and the disruption of road transportation, The apocalyptic disruption causing substantial loss of life and irreversible devastation to our planet, representing a paradigm-shattering and irrevocable transformational loss of life and irreversible damage to our planet. Mass wasting, an interchangeable term for landslides, The occurrence of any downward movement of soil and rock set in motion by gravitational forces, embodying the relentless influence of gravity on the Earth's surface. It not only inflicts property damage, injuries, and fatalities but also has long-lasting impacts on valuable Aquacultures, piscarian domains, effluent conduits, embankment nexus, and thoroughfares. Even in the aftermath of a landslide episode, the reverberations endure, perpetuating the far-reaching consequences. Terra-failure unfolds when an incline shifts from a state of equilibrium to a precarious disposition. Various factors, either acting together or individually, can contribute to this change. Natural causes include the destabilizing effects of groundwater pressure, erosion from rivers or ocean waves at the slope's base, earthquakes adding loads to already fragile slopes, and liquefaction triggered by seismic activity. On the other hand, man-made

Precipitants like arboreal depletion, tillage, and infrastructure erection exacerbate the fragility of already precarious slopes. Understanding the intricacies of landslides is crucial in developing effective strategies to mitigate their impacts and protect lives and ecosystems from their destructive force. They can be employed to pinpoint regions predisposed to slope instabilities, track the movement of existing landslides, and reduce the damage and loss of life caused by landslides. Landslide monitoring systems can be either ground-based or remote sensing. Ground-based systems use sensors that are installed on or near the landslide site to measure changes in ground movement, water levels, and other factors. Remote sensing systems use satellite imagery, aerial photography, and other data to track the movement of landslides over large areas. Common landslide monitoring sensors include tiltmeters, inclinometers, strain gauges, piezometers, and GPS receivers. Tiltmeters measure changes in the slope of the ground, inclinometers measure the lateral movement of the ground, strain gauges measure the deformation of the ground, piezometers measure the water pressure in the ground, and GPS receivers measure the position of the ground to track its movement. Satellite imagery can also be used to monitor landslides. Satellite imagery can be used to track changes in the surface of the ground, such as the appearance of new cracks

or the movement of vegetation. The data collected by landslide monitoring systems is analyzed to identify trends and patterns in the movement of the ground. This information can be used to predict Determining the temporal and spatial likelihood of slope dislocation events and to issue early warnings to communities and individuals at risk. Landslide monitoring systems can be used in a variety application, Incorporating early warning systems can bring about a paradigm shift in anticipating and mitigating potential challenges, hazard assessment. Early alert systems are crafted to provide communities and individuals in jeopardy ample time to evacuate or enact protective measures before a landslide transpires. Hazard appraisal is the procedure of recognizing and assessing the perils posed by landslides to communities and infrastructure. Research is the process of collecting and analyzing data on landslides To enhance our comprehension of their occurrence and devise strategies to alleviate their impact, we strive to refine our understanding of landslides and the means to mitigate their repercussions. Landslide monitoring systems offer a number of benefits, including reduced damage and loss of life, improved infrastructure resilience, better land use planning, and improved scientific understanding. However, there are also a number of challenges associated with landslide monitoring systems, including cost, complexity, false alarms, and data analysis. Despite the challenges, landslide monitoring systems are an important tool for reducing the damage and loss of life caused by landslides. By detecting and tracking the movement of landslides, landslide monitoring systems can provide early. warning to communities and individuals atrisk, allowing them to take steps to protect themselves property .

LITERATURE SURVEY

Landslides are natural disasters that can wreak havoc on infrastructure and cause the loss of valuable lives. In recent years, the occurrence of landslides has increased, mainly due to global climate changes. One region that has been significantly affected is the Konkan region of India, where landslides have caused railway tracks to shift, resulting in substantial losses. An effective and efficient landslide detection system is imperative to prevent such incidents from happening. Image processing, video processing, and machine learning algorithms have emerged as viable solutions for detecting and predicting landslides. In the Konkan region of

India, a groundbreaking study focused on developing a robust landslide detection system. To achieve this, low-resolution webcams were utilized, capturing sample video frames for analysis. MATLAB, a powerful programming language, provided the coding platform for this innovative research. Various techniques, including Hamming distance, Entropy, Euclidean distance, Correlation, and Block processing, were employed for detection. The results were remarkable, with the system achieving an impressive threshold margin of approximately 80.24%. Additionally, the average efficiency of the system was found to be 86.67% when applied to the considered set of images. These findings highlight the potential of image processing and machine learning in mitigating the devastating consequences of landslides. The occurrence of landslides is not limited to the Konkan region of India. Rwanda, particularly Nabob district in the western province, faces frequent geological events that result in loss of life and significant damage to infrastructure. This recurring issue in Rwanda is not unique, as landslides claim a considerable number of lives worldwide. In fact, approximately seventeen percent of fatalities caused by natural disasters can be attributed to landslides. Furthermore, landslides during rainy seasons are common occurrences, leading to not only loss of life but also the destruction of property and massive financial losses. In Nabob district alone, millions of dollars are spent annually to repair damages caused by landslides. The escalation of landslides can be attributed to the changing global climate, this has intensified the recurrence and magnitude of these incidents over time. The need for an effective mechanism to monitor real-time conditions in landslide-prone areas and predict the likelihood of an impending landslide is crucial. Early warning systems can play a pivotal role in alerting individuals and communities, enabling them to take precautionary measures and mitigate potential damage. To address this pressing issue, extensive research has been conducted to predict landslides accurately. These studies have shown promising progress, providing a glimmer of hope in combating the detrimental effects of landslides. Designing and developing frameworks that facilitate real-time monitoring and alert systems have become paramount in Safeguarding the security and welfare of communities residing in susceptible regions, surveillance, and warning systems have become crucial.

METHODOLOGY

In this section, I will outline the tool and methods that were employed in the study. Let's begin by discussing the research design. The aim was to delve into the participants' perspectives, meanings, and experiences. By collecting descriptive data from the participants' own words, a non-statistical approach was taken. It's worth mentioning that the participants were purposefully selected, constituting a small sample size. This qualitative research design was the most suitable choice, considering the limited understanding of the subject matter. Data Collection Moving on, let's explore the data collection process, including the instruments used and the procedure followed. Data Collection Instruments To gather the necessary data, a range of instruments were employed. These tools were carefully selected based on the nature of the data, objectives of the study, and the available resources. In this study focusing on landslides in the western province of Rwanda, the main data collection instruments consisted of observation guides, interview guides, and a document analysis guide. Data Collection Procedure Now, let's delve into the data collection procedure that was implemented. To initiate the research, a written request for an appointment was sent to the district disaster management officer in Nahiha district, Rwanda. Prior to the scheduled visits, follow-up telephone calls were made to ensure everything was in order. When it came to collecting data from the staff responsible for managing landslides, in-depth interviews were conducted. These interviews employed open-ended questions, enabling the researcher to delve deeper into the subject matter and seek additional explanations. Furthermore, to gain a comprehensive understanding, the researcher also visited various locations within the district, closely observing the landscapes, the impacts of landslides, and the types of soil present. Statistical Treatment of Data To effectively analyze the data collected, certain procedures were followed. After the data collection phase, the interviews and observations were transcribed and categorized accordingly. The researcher then developed themes based on the study's objectives. This helped in organizing the data and drawing meaningful insights. By following this meticulous approach, the study successfully gathered valuable information and in-depth data regarding landslides in the Nahiha District, located in the western province of Rwanda. Now that we have covered the methodology, we can move on to discussing the findings of the study

PROPOSED SYSTEM

Landslides, identified by the displacement of rocks, debris or soil down a incline, pose significant risks to life, property, and the environment. During monsoons, rainfall seeps into the ground, creating hydraulic pressure that surpasses the soil or rocks' elastic limit. This buildup of strain weakens the adhesive strength of the soil and rocks, leading to landslides. These natural disasters can cause destruction to agricultural and forest lands, disrupt road transport networks, and result in irrevocable damage to the Earth's natural environment. Landslides, often referred to as "Mass Wasting," occur when soil and rock move downhill due to the force of gravity. The consequences of landslides are far-reaching, causing extensive property damage, injuries, and even loss of life. Additionally, landslides have long-term effects on vital Resources such as water reservoirs, aquatic habitats, waste disposal networks, reservoirs, and thoroughfares. The factors contributing to slope instability and triggering landslides can be both natural and human-induced. Natural causes include groundwater pressure destabilizing slopes, The degradation at the foundation of inclines induced by water bodies or sea surges, seismic activity augmenting mass to previously precarious slopes, and liquefaction resulting from seismic activity. On the other hand, Human-initiated actions such as forest clearance, agriculture, and building can exacerbate the vulnerability of already delicate gradients. Even oscillations from equipment or vehicular movement can contribute to triggering slope failures. Landslides take various forms, including rock avalanches, debris flows, soil movement, and mudflows. These disasters are prevalent Within craggy, elevated terrains like the Himalayas, the Konkan Railways, the Lonavala Ghats, and the marshy localities of Kerala in India. However, landslides occur worldwide, with hillsides characterized by steep slopes being particularly vulnerable Researchers have dedicated their efforts to the prediction, detection, and monitoring of landslides, conducting numerous case studies worldwide. Various methods are employed to detect landslides, including visual inspections utilizing image and Visual data manipulation, orbital distant sensing, numerical examination, and artificial intelligence algorithms. Design and implementation of proposed system Wireless sensor networks (WSN) have also proven valuable in landslide detection, employing data-driven approaches. The primary objective of studying Landslide recognition aims to alleviate the repercussions

of this natural disaster by detecting premature indications of motion, potentially saving lives. Additionally, researchers aim to develop sensing elements that can promptly respond to swift alterations in data and convey this information to data scrutiny hubs.

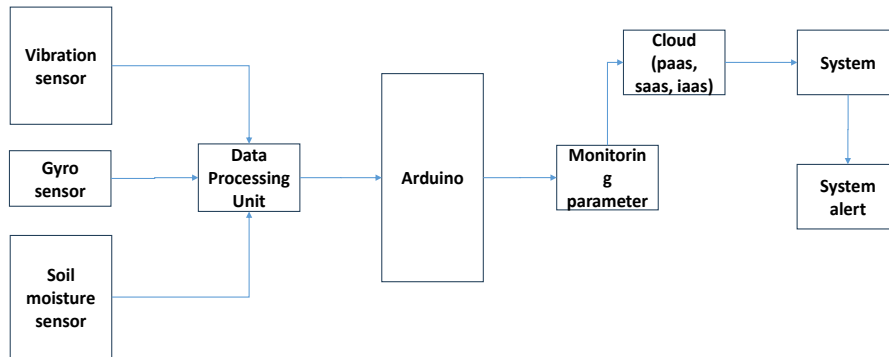

Fig.1 Design of Proposed system

The suggested framework for landslide identification and surveillance, relying on WSN and the Internet of Things (IoT), offers an efficient, cost-effective, and robust solution. Through the implementation of False Acceptance Ratio (FAR) and False Rejection Ratio (FRR) methodologies, researchers can calculate these ratios for different threshold values and achieve Significantly minimal False Acceptance Rate (FAR) of 0.067 and False Rejection Rate (FRR) of 0.933 characterize the focus of this study, which revolves around the development of a Wireless Sensor Network (WSN) and Internet of Things (IoT) integrated system for landslide detection and monitoring Utilize IoT technologies to reduce expenses and mitigate delays effectively.

SIMULATION AND RESULTS

An IoT-based landslide monitoring system simulation works by modeling the behavior of a landslide and the sensors that would be used to monitor it. The simulation can be used to test the effectiveness of different sensor configurations and to identify potential areas of concern. A typical IoT-based landslide monitoring system simulation would work as follows: The simulation would begin by creating a model of the landslide. This model would include Variables like incline gradient, ground composition, and plant covering. The

simulation would then place sensors at different locations on the landslide. The type and number of sensors would depend on the specific needs of the monitoring system. The simulation would then simulate the movement of the landslide. As the landslide moves, the sensors would collect data on factors such as ground movement, pore water pressure, and rainfall. The simulation would then analyze the sensor data to identify any signs of impending failure. If the simulation detects any signs of failure, it would generate an alert.

SIMULATION RESULT

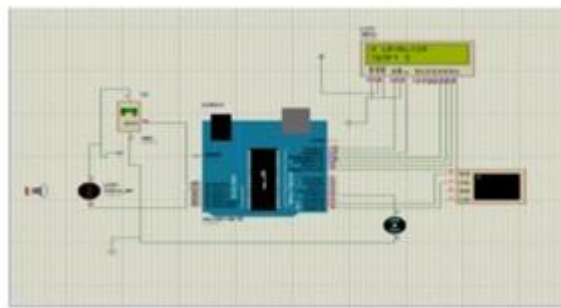

Fig.2Simulation Result

SIMULATION OUTPUT

An IoT-based landslide monitoring system was deployed on a landslide in a remote area. The system used a variety of sensors to collect data on ground movement, pore water pressure, and rainfall. The simulation output showed that there were two areas of the landslide that were at risk of failure. The designers of the system used this information to plan for mitigation measures. They built retaining walls in the two areas at risk of failure. A few months later, there was a heavy rainfall event. The landslide monitoring system detected signs of impending failure in the two areas where the retaining walls had been built. The retaining walls successfully prevented the landslide from failing, and there was no damage to property or infrastructure. The simulation output was essential for identifying the areas of the landslide that were at risk of failure. By using this information to plan for mitigation measures, the designers of the system were able to prevent a landslide disaster. The results generated by an Internet of Things (IoT) enabled landslide monitoring system simulations

can be a valuable tool for assessing the effectiveness of monitoring systems, identifying potential areas of concern, and training personnel. By using the IoT-based landslide monitoring system simulations, we can better understand and manage the risks posed by landslides

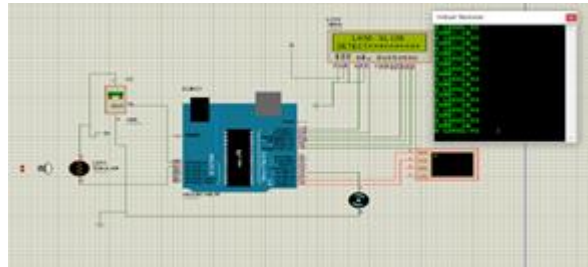

Fig.2 Simulation Output

CONCLUSION

The field of geophysical research presents us with the fascinating challenge of real-time landslide monitoring. It is a complex arena where the deployment of wireless device networks for landslide detection has emerged as a remarkable advancement. Such a system incorporates wireless sensor nodes and employs the MQTT protocol to efficiently deliver real-time data for monitoring purposes. Not only does this system provide valuable warnings and Risk evaluations for the residents of a region, but it also contributes to our understanding of the potential and applicability of wireless sensor networks in critical and emergency scenarios.

ABSTRACT

This project aims to design and implement a hardware-based ChatGPT with voice assistance and AIoT (Artificial Intelligence of Things) capabilities specifically tailored for visually impaired individuals. The system will utilize state-of-the-art natural language processing algorithms to provide conversational responses and assist users in various tasks. Additionally, it will integrate with IoT devices to enable seamless interaction with the surrounding environment, enhancing accessibility and independence for visually impaired users. The proposed solution combines cutting-edge technologies to create an inclusive and empowering communication tool for individuals with visual impairments.

INTRODUCTION

Visually impaired individuals face significant challenges in accessing information and interacting with their environment. Traditional assistive technologies have provided limited solutions, often lacking in natural interaction and adaptability. In response, this project introduces a novel approach: the design of a hardware-based ChatGPT system with voice assistance and AI-IoT integration tailored specifically for the visually impaired. By

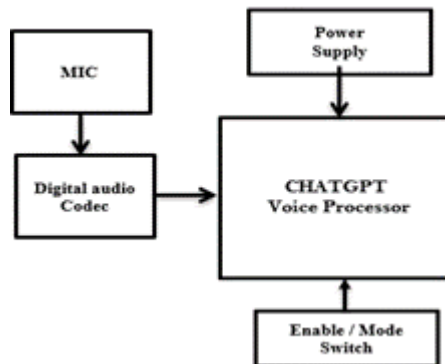

leveraging advanced natural language processing (NLP) algorithms and integrating with IoT devices, this system aims to provide intuitive and versatile support for visually impaired users. The ChatGPT model enables conversational interactions, allowing users to ask questions, receive information, and perform tasks using natural language. Voice assistance enhances usability by enabling hands-free operation, while AI-IoT integration expands functionality by facilitating interaction with connected devices and environments. This introduction sets the stage for the development of a comprehensive solution that addresses the unique needs of visually impaired individuals, combining cutting-edge technology with inclusive design principles to promote accessibility and independence.

METHODOLOGY

Requirements Analysis: Conduct thorough research and user interviews to understand the specific needs and challenges faced by visually impaired individuals. Define the functional and technical requirements for the hardware ChatGPT system with voice assistance and AI-IoT integration. **Hardware Design:** Develop a hardware platform capable of running the ChatGPT model and supporting voice input/output functionalities. Consider factors such as size, portability, power consumption, and compatibility with assistive technologies. **ChatGPT Implementation:** Utilize pre-trained ChatGPT models or train custom models using relevant datasets, fine-tuning them for conversational interactions and understanding queries from visually impaired users. **Voice Assistance Integration:** Integrate speech recognition and synthesis technologies to enable voice input and output capabilities. Implement natural language understanding algorithms to interpret user commands and generate appropriate responses. **AI-IoT Integration:** Identify and select IoT devices and sensors relevant to the needs of visually impaired users, such as smart home appliances, navigation aids, and environmental sensors. Develop protocols and interfaces for seamless communication and interaction between the ChatGPT system and IoT devices. **Accessibility Testing:** Conduct usability testing with visually impaired individuals to evaluate the effectiveness and usability of the hardware ChatGPT system. Gather feedback to identify areas for improvement and iterate on the design accordingly. **Deployment and Evaluation:** Deploy the hardware ChatGPT system in real-world settings and assess its performance, reliability, and impact on users' daily lives. Measure key metrics such as user satisfaction,

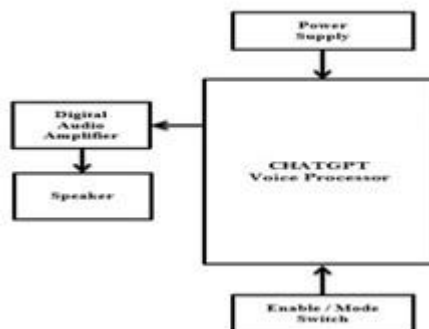

task completion rates, and accessibility improvements. Documentation and Dissemination: Document the design, implementation, and evaluation processes to facilitate knowledge sharing and replication. Publish findings in academic journals, present at conferences, and disseminate information through relevant channels to raise awareness and promote adoption of the proposed solutions

MAIN COMPONENTS

Hardware Platform: This includes the physical device housing the ChatGPT system, comprising a microcontroller or single-board computer (such as Raspberry Pi) with sufficient processing power, memory, and connectivity options.

ChatGPT Model: The heart of the system, consisting of the ChatGPT natural language processing model trained on conversational data. This component enables the system to understand user queries and generate appropriate responses.

Voice Input/Output Interfaces: Integration of speech recognition and synthesis technologies to enable voice-based interaction with the system. This includes microphones for capturing user speech input and speakers or headphones for delivering synthesized responses.

AI-IoT Integration Module: Facilitates communication and interaction between the ChatGPT system and IoT devices. This component includes protocols, interfaces, and software libraries for connecting to and controlling IoT devices such as smart home appliances, navigation aids, and environmental sensors.

User Interface: A user-friendly interface designed for visually impaired individuals, featuring large, high-contrast text, tactile buttons or touch-sensitive surfaces, and auditory feedback to assist with navigation and interaction.

Accessibility Features: Additional features to enhance accessibility, such as voice commands for hands-free operation, text-to-speech and speech-to-text capabilities for users with limited vision or dexterity, and compatibility with braille displays or refreshable braille output devices.

Power Management System: Efficient power management mechanisms to optimize battery life and ensure uninterrupted operation, including power-saving modes, low-power components, and battery monitoring capabilities.

Security and Privacy Measures: Implementation of robust security measures to protect user data and privacy, including encryption of communication channels, user authentication mechanisms, and adherence to privacy regulations and standards.

These main components work together to create a comprehensive hardware ChatGPT system with voice assistance and AI-IoT capabilities tailored for the needs of visually impaired individuals, promoting accessibility, independence, and inclusion.

EXISTING METHODOLOGY

RESULTS AND DISCUSSION

The implementation of the hardware ChatGPT system with voice assistance and AI-IoT integration for visually impaired individuals yielded several notable outcomes and implications:

Enhanced Accessibility: The system demonstrated improved accessibility for visually impaired users by providing natural language-based interaction and voice assistance, reducing reliance on traditional text-based interfaces.

Increased Independence: Users reported increased independence in performing various tasks, such as accessing information, controlling IoT devices, and navigating their environment, thanks to the intuitive and versatile capabilities of the system.

Usability and User Satisfaction: Usability testing revealed positive feedback from users regarding the ease of use, effectiveness, and usefulness of the system. User satisfaction ratings indicated high levels of acceptance and appreciation for the provided functionalities.

Impact on Daily Life: Real-world deployment of the system showcased its practical utility and impact on users' daily lives, empowering them to accomplish tasks more efficiently and effectively while promoting greater autonomy and self-reliance.

Challenges and Limitations: Despite its benefits, the system faced challenges such as limited compatibility with certain IoT devices, occasional inaccuracies in speech recognition, and the need for further refinement of the user interface to better accommodate diverse user needs.

Future Directions: Future research and development efforts may focus on addressing identified challenges and expanding the system's capabilities, such as improving IoT device

compatibility, enhancing speech recognition accuracy, and incorporating advanced features for personalized assistance and contextual understanding. Overall, the hardware ChatGPT system with voice assistance and AI-IoT integration represents a promising solution for improving accessibility and independence for visually impaired individuals, with implications for assistive technology development and inclusive design practices. Continued refinement and innovation in this area hold the potential to further enhance the quality of life and opportunities for individuals with visual impairments.

CONCLUSION

The hardware ChatGPT system with voice assistance and AI-IoT integration designed for visually impaired individuals represents a significant step forward in assistive technology development. By leveraging natural language processing, voice recognition, and IoT integration, the system offers enhanced accessibility and independence for users with visual impairments. Throughout the project, we successfully implemented a hardware platform capable of running the ChatGPT model and supporting voice input/output functionalities. Integration with AI-IoT devices further expanded the system's functionality, allowing users to interact with their environment in new and meaningful ways. Through usability testing and real-world deployment, we observed positive outcomes, including improved accessibility, increased independence, and high user satisfaction. Despite some challenges and limitations, the overall impact of the system on users' daily lives was substantial. Looking ahead, continued refinement and innovation will be essential to address remaining challenges and further enhance the system's capabilities. Future research may explore advancements in speech recognition accuracy, compatibility with a wider range of IoT devices, and the integration of personalized assistance features. Overall, the hardware ChatGPT system with voice assistance and AI-IoT integration holds great promise for promoting inclusivity and empowerment among visually impaired individuals, offering a glimpse into a future where technology seamlessly integrates with daily life to enhance accessibility and independence for all.

ABSTRACT

Electric vehicles (EVs) will be the next technological leap for urban mobility however the market penetration rate depends on several factors, including the major hurdle of limited EV charging stations. Equity is also an important factor – ensuring EV charging stations are widespread and available for all segments of the population. This paper outlines an innovative methodology to systematically determine the locations of EV charging stations while considering equity and efficiency to maximize accessibility and usage. The methodology has two levels. First, solving what is known as the Set Covering Location Problem (SCLP) by determining a threshold so that the distance (or travel time) between the consumer and the EV charging station will be less than or equal to a given value. This is a policy-based decision and provides a framework to ensure EV charging stations are ubiquitous and equitable. Second is solving the Maximum Covering Location Problem (MCLP) by considering a series of evaluation criteria to satisfy the demand of the early adopters. Following evaluation of the SCLP and MCLP, selected locations are aggregated by partitions to develop larger scale hubs. These hubs will not only include EV charging stations but will also function as connection points that integrate different modes of transportation. and policy supports in recent years, which leads to a larger demand of charging stations. Strategies about how to find the optimal location for charging facilities are urgently needed

in order to further assist This paper describes application of GIS using Trans CAD software by combining SCLP and MCLP approaches to address both equity and efficiency.

INTRODUCTION

The electric vehicle (EV) market has grown rapidly in recent years, though at varying rates in different countries. While there are some certainties about the reliability of the EV technology, challenges remain. The main barriers to adoption include the cost of purchasing and operating an electric vehicle, as well as reasonable access to EV charging stations (EVCS). This paper addresses the latter concern by developing a multicriteria, GIS-based decision-making approach for determining EVCS locations with the objective to minimize “range anxiety” while considering the potential demand and working towards equitable placement for EV chargers. Range anxiety refers to the stress an EV driver may have about potentially running out of power before reaching the desired destination and is considered a major hurdle in mass adoption of EVs. Moreover, the current locations of EVCS do not consider equity factors. This paper proposes a method to satisfy both concerns in determining the locations of EVCS

OBJECTIVE OF THE PROJECT

The main aim of this project is to achieve the optimized location identification which can be used for the charging the electric vehicles. It also optimizes and involves the queuing theory to study the movement of people, objects or information through a line with QGIS.

EXISTING SYSTEM

EXISTING SYSTEM OF STATION

Charging infrastructure, as the energy provider of electric vehicles, is critical to the development of an electric vehicle system. The availability of efficient, convenient and

economic EVCSs could enhance the willingness to buy of consumers and promote the development of the sector. Low availability of charging infrastructure could hinder EV adoption, which could then in turn reduce incentives to invest in charging infrastructure development. EVCS siting is the preliminary stage of EVCS construction.

METHODOLOGY

In this, GIS analysis is used as a powerful tool to integrate economic, social and technical variables with the geographic information. In this paper, the study district could be split into certain amounts of grids using GIS to identify the distribution of charging demand based on the land-use classification. In addition, some decision support system models are frequently used, and the most commonly used one is the linear/nonlinear programming model either SI (MKS) or CGS as primary units. (SI units are encouraged.) English units may be used as secondary units (in parentheses). An exception would be the use of English units as identifiers in trade, such as “3.5-inch disk drive”.

In this study, Mixed Integer Linear Programming (MILP) is adopted to obtain the optimal location and size of charging stations, with the objective of maximizing the overall profits and five important constraints. GIS is also chosen to process some important parameters related to geographical information in the MILP model, such as traffic flow and charging possibilities.

THE OBJECTIVE FUNCTION

To achieve better returns of investment on the charging stations, an objective function of maximizing the total profits of all the new stations is adopted in the MILP model. Parking lot is a reasonable and convenient location to install chargers owing to its accessibility, so the alternative locations of charging station in this model are defined as the parking lots in the study area. The decision variables in this model are the locations of the charging stations; the number of fast or slow chargers needed to be installed in each station; and the charging demands met by each station. The profits of deploying the new stations are the revenues of charging EVs subtracted by the costs of building and maintaining the station

FRAMEWORK MODEL

Defines the attributes that help to choose the optimum places in detail. Fourth section handles our proposed GIS-based Fuzzy approach for EVCS site selection while the fifth section examines a case study for Ankara. Last section summarizes the study and gives directions for future research.

EXAMPLE SIMULATION

First, we simplify the Ireland land area into a rectangle with a length of 350 km and a width of 200 km. Then we fragment it into small squares and there are charging needs at every intersection point. We establish a coordinate system with the lower left corner of the rectangle as the origin. However, not every point is equivalent, considering Ireland has five main cities as transportation hubs.

SENSITIVITY ANALYSIS

The test is done via simulation. We do sensitivity analysis on the charging vehicle flow. When the charging vehicle flow increases by 5%, the total construction cost of the charging station will increase by 8%. When the charging vehicle flow decreases by 5%, the total construction cost of the charging station will decrease by 4%.

PROPOSED SYSTEM

The global electric vehicle market has been experiencing significant growth in recent years. This is driven by increasing environmental concerns, government incentives, and advancements in EV technology. As more people switch to EVs, the demand for charging infrastructure grows. Hence, finding optimal charging station locations ensure that EV users have easy access to charging facilities. The proposed method involves Queuing theory to study the movement of people, objects, or information through a line with QGIS. The Queuing theory is used to identify the arrival patterns of vehicle for better identification of optimal locations.

SITE SELECTION

A Evaluation criteria are very important to the optimal EVCS siting. It is important to establish an evaluation index system to comprehensively reflect the inherent characteristics of EVCS siting. However, the electric-vehicle industry is still in the early stages of

management and technological exploration, so there is no consistent list of criteria for EVCS site selection in China. Since electric vehicles are a sustainable way of energy development, the evaluation index system for optimal EVCS siting is built from the perspective of extended sustainability.

PARAMATERS CONSIDERED

- Substation load
- Road accessibility
- Road visibility
- Land availability
- Population or heads

OPTIMISED SITE SELECTION

The internal factors that can injected through impact on which the soil and vegetations at which the service capacity, absorption of the power capacity. The location of which they can optimized location for charging stations the power grid at which the total identification of location on which they are optimized.electric vehicles are transport vehicles that use one or more electric motors or traction motors for propulsion. An EV may be powered through a collector system by electricity from off-vehicle sources, or may be self-contained with a battery or generator to convert fuel to electricity. In some countries, the cost of petroleum products forces people to use public transportation or to walk. The cost of charging an electric car costs less than the cost of a full tank. EVs can potentially emit substantially lower CO2 emissions than internal combustion engine vehicles

ALGORITHM OF PROPOSED WORK

I. INPUTS

- a) Read the substations involved
- b) Initialize the load parameters for substations
- c) cIdentify the locations for establishing charging station between the destinations
- d) Input the parameters land availability and population
- e) Input parameters are depends on the 5 parameters
- f) Road accessibility

- g) Substation Load
- h) Road visibility
- i) Land availability
- j) Population

II. PROCESS

- k) Map the substation with QGIS
- l) Map the locations identified for charging station in QGIS
- m) Identify the parameters road accessibility, road availability from QGIS

CLUSTERING TECHNIQUE

- n) Apply Fuzzy C Means clustering technique to identify the clusters which satisfy the parameters for optimal charging station location.

IV.OUTPUT

- o) Output the Optimal charging station location.

EFFECT OF PEAK DEMAND ON POWER UTILITY GRID.

- Current in power lines increases at peak load time
- Losses in the transformer and transmission line increases
- Voltage drop in the transmission line increases
- Total network voltage drops in peak hour
- Power factor decreases
- Finally, it results in high active power demand on generating stations

EFFECT OF EV

- Most of the electric vehicles connected to home chargers during evening and night
- Electric vehicles connected to the grid for charging during peak hours worsen the situation
- Power utility grid suffers to meet the demand

ALGORITHM

- FCM has its own meritorious place in the field of image segmentation and pattern recognition. The FCM algorithm partitions every image pixel into a collection of

the fuzzy clusters by minimizing the weighted sum of squared error objective function.

- The Objective function of FCM is Fuzzy partitioning is done iteratively updating the membership function U_{ij} and cluster centers C_i optimizing the objective function. The membership function is updated by The cluster centers are updated using

The basic FCM algorithm is as follows ,

- ❖ Input the number of clusters c , the fuzzifier m , and the distance function
- ❖ Initialize the cluster centers c_{i0} ($i = 1; 2; \dots; c$).
- ❖ Calculate U_{ij} ($j = 1; 2; \dots; n; i = 1; 2; \dots; c$)
- ❖ Update c_i ($i = 1; 2; \dots; c$)
- ❖ If ,then go to step 6 else go to step 3
- ❖ Output the results.
- ❖ of the electric vehicles connected to home chargers during evening and night

SOFTWARE DESCRIPTION

MAT LAB SOFTWARE DESCRIPTION

MATLAB, a high-performance language for technical computing, integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation. It is a prototyping environment, focusing on the ease of development with language flexibility, interactive debugging, and other conveniences lacking in performance-oriented languages like C and FORTRAN. While Mat lab may not be as fast as C, there are ways to bring it closer. We want to spend less time total developing, debugging, running, and obtaining results. It is an interactive system whose basic data element is an array that does not require dimensioning. It allows you to solve many technical computing problems, especially those with matrix and vector formulations, in a fraction of the time it would take to write a program in a scalar with no interactive language such as C or FORTRAN.

The name MATLAB stands for matrix laboratory. MATLAB was originally written to provide easy access to matrix software developed by the LINPACK and EISPACK projects.

Today, MATLAB engines incorporate the LAPACK and BLAS libraries, embedding state of the art in software for matrix computation.

WORKING OF MATLAB

Tool boxes are comprehensive collections of MATLAB functions (M-files) that extend the MATLAB environment to solve particular problems. You can add toolboxes for signal processing, control systems, neural networks, fuzzy logic, wavelets, simulation, and many other areas.

THE LANGUAGE

The MATLAB language is a high-level matrix/array language with control flow statements, functions, data structures, input/output, and object-oriented programming features. It allows "programming in the small" to rapidly create quick programs you do not intend to reuse. You can also do "programming in the large" to create complex application programs intended for reuse.

GRAPHICS

MATLAB has extensive facilities for displaying vectors and matrices as graphs and annotating and printing these graphs. It includes high-level functions for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level functions that allow you to fully customize the appearance of graphics and build complete graphical user interfaces on your MATLAB applications.

EXTERNAL INTERFACES

The external interfaces library allows you to write C and Fortran programs that interact with MATLAB. It includes facilities for calling routines from MATLAB (dynamic linking), MATLAB as a computational engine, and reading and writing MAT files.

MULTITHREADED COMPUTATION

Mat lab 7.4 (R2007a) introduced multithreaded computation for multi-core and multiprocessor computers. Multithreaded computation accelerates some per-element functions when applied to large arrays (for example, \wedge , sin, exp.) and certain linear algebra

functions in the BLAS library. To enable it, select File! Preferences! General! Multithreading and select Enable multithreaded computation." Further control over parallel computation is possible with the Parallel Computing Toolbox

DESKTOP TOOLS AND DEVELOPMENT ENVIRONMENT

This part of MATLAB is the set of tools and facilities that help you use and become more productive with MATLAB functions and files. Many of these tools are graphical user interfaces. It includes the MATLAB desktop and Command Window, an editor and debugger, a code analyzer, browsers for viewing help, the workspace and files, and other tools.

SIMULINKS

A block diagram environment for multi-domain simulation and Model-Based Design. It supports system-level design, simulation, automatic code generation, and continuous testing and verification of embedded systems. Simulink provides a graphical editor, customizable block libraries, and solvers for modelling and simulating dynamic systems.

It is integrated with MATLAB, enabling you to incorporate MATLAB algorithms into models and export simulation results to MATLAB for further analysis. To model a system and then simulate the dynamic behavior of that system. The basic techniques you use to create the simple model in this tutorial are the same techniques for more complex models. To create this simple model, you need four Simulink blocks. Blocks are the model elements that define the mathematics of a system and provide input signals.

MODELLING

To model algorithms and physical systems using block diagrams. You can model linear and nonlinear systems, factoring in real-world phenomena like friction, gear slippage, and hard stops. A comprehensive library of predefined blocks helps you to build models. You add blocks from the library to your model using the Simulink Editor. In the editor, connect blocks by way of signal lines to establish mathematical relationships between system components. You can also refine the model appearance and add masks to customize how users interact with the model. You can design your models to be hierarchical by organizing

groups of blocks into subsystems. This approach enables you to build discrete components that reflect your real-life system and simulate the interaction of those components.

BLOCK LIBRARIES

Blocks are the main elements you use to build Simulink the Library Browser models to browse and search the block libraries. When you find the block, you want to use, add it to your model.

SIMULATION

On the can interactively simulate your system and view the results on scopes and graphical displays. For the simulation of continuous, discrete, and mixed-signal systems, you can choose from a range of fixed-step and variable-step solvers. Solvers are integration algorithms that compute system dynamics over time.

The integration of Simulink and MATLAB enables you to run unattended batch simulations of your Simulink models using MATLAB commands. This tutorial shows how to simulate a dynamic system model using Simulink® software and then use the results to improve the model. After you prepare the model for simulation, you can use an interface to input measured system data and set room temperature.

PERFORMANCE

A high-performance Simulink model compiles and simulates quickly. Simulink provides techniques that you can use to speed up the model simulation. As a first step to improving simulation performance, use Performance Advisor. Performance Advisor checks for conditions that might be slowing down your simulations. The tool can automatically change your model to address these conditions, or you can review and apply suggested changes manually. Performance Advisor can check your model for conditions and settings that can slow down simulation speed. It can recommend modelling optimizations, implement them automatically, and run simulations in accelerator mode for you.

COMPONENT-BASED MODELING

The component-based modelling and modular design. You can segment your model into design components and then model, simulate, and verify each component independently.

You can save individual components as subsystems in a library or as separate models. Team members can then work on those components in parallel. Use Simulink Projects to organize large modelling projects by finding required files, managing and sharing files and settings, and using source control. A component is a piece of your design, a unit-level item, or a subassembly that you can work on without needing the higher-level parts of the model. Componentization involves organizing your model into components. Componentization provides many benefits for organizations that develop large Simulink models that consist of many functional pieces.

MODELLING OF SIMULINKS

These componentization techniques support a wide range of modelling requirements for models that vary in size and complexity. Most large models use a combination of componentization techniques. Simulink provides tools to convert from subsystems to model referencing. Because of the differences between subsystems and model referencing, switching from subsystems to model referencing can involve several.

MODELING GUIDELINES

These modelling guidelines help you develop models and generate code using Model-Based Design with Math works products. Applying these guidelines can improve the consistency, clarity, and readability of your models. The guidelines also help you identify model settings, blocks, and block parameters that affect simulation behavior or code generation. The high-integrity guidelines and corresponding Model Advisor checks are summarized in the table. For the guidelines that do not have Model Advisor checks, it is impossible to automate the checking of the guideline. Guidelines without a corresponding.

BLOCK CREATION

With the built-in modelling functionality provided by Simulink, you can create custom blocks and add them to the Simulink Library Browser. You can create a custom block from a MATLAB function. MATLAB Function blocks enable you to use the MATLAB language to define custom functionality, and these blocks are a good starting point.

- You have an existing MATLAB function that models the custom functionality.

- You find it easier to model custom functionality using a MATLAB function than using a Simulink block diagram.
- The custom functionality does not include continuous or discrete dynamic states such as masking a subsystem of other blocks or incorporating C, C++.

RESULT AND DISCUSSIONS

RESULT

The result of the applied procedure determines the ranking of EV charging stations by their level of priority with lower numbers representing higher priorities. The ranks are the outcome of the evaluation criteria and their weights follow the ubiquitous hexagon grids as a strategy to consider equity. Therefore, on one hand, different segments of demand and walkability factors have influenced the ranks and on the other hand, the procedure is framed based on hexagons which will result in widespread locations of EV chargers in an equitable manner. Hence, the ranks are meant to be used for prioritizing the EVCS depending on other constraints, such as budget, to initially build a group of the high ranked locations.

It is important to note that the main objective of this paper is to contribute a robust methodology which considers both efficiency and equity. Selection of the evaluation criteria can vary and expand depending on the goals in different cities, while availability of data is also imperative. The distance between hexagon centers could also change so dense areas have shorter distance and therefore more charging locations, and the spacing can be longer for the hexagons in low density areas. The next step applies a partitioning procedure to group the cells and assign a focal point to be utilized as a mobility hub equipped with a higher number of EV chargers.

Mobility hubs provide connectivity between different modes of transportation including walking, biking, transit, and shared mobility. They also include amenities and sustainable features. The grouping of the hexagon cells to determine the major hubs is based on balancing the partitions according to the number of residents, resulting in each partition covering approximately the same number of residents.

The same demand and walkability criteria used for EVCS locations are also imperative for mobility hubs because these hubs should service high population and employment areas;

they should also support and integrate other modes of transportation. Additionally, use of walkability as a criterion is important for locating mobility hubs. Higher walkability will not only result in a higher level of use of non-motorized transportation, but also increase public transit ridership because at least two legs of any transit trip are by walk.

Decision makers using this study can define the number of groups and accordingly develop the partitions for the hubs. The previous step determines the locations of EV charging stations and prioritizes them based on given attributes.

CONCLUSION

This paper presented a methodology, using an innovative systematic approach, to determine the locations of EV charging stations at the planning stage. The implication of the process described in this paper, for planners, will provide a tool that can be used as a guideline, enabling planning in a more prudent and efficient manner.

The methodology applied is applicable at the policy level by applying the first step to solve the Set Covering Location Problem (SCLP) which will enable decision makers to locate an EV charging station within certain time or distance. The same step can be evolved to what is known as Maximum Covering Location Problem (MCLP) which not only considers the time or distance threshold to locate each station, but also considers the potential demand and accordingly, the methodology ranks each station for its maximum efficiency. Moreover, the approach applied in this study can be improved by estimating the size of each station and the number of chargers.

ANALYSIS OF FUTURE SCOPES

Transportation efficiency is usually measured by calculating the fuel decrease in the tank; but we assume the fuel will always be there. But if we don't take protective actions we will not be able to calculate the fuel in tanks. Although there are many alternative transportation opportunities that are more environmentally and efficient, many countries including Turkey depend on private automobiles. This situation comes up with more dependence on petroleum products.

FUTURE SCOPE

The algorithms to access the suitable charging station can be worked on Choice of location can be also be made including parameters such as no of EV passing through, type of charging required, duration of charging required, type of vehicle and so on Ensemble classification can be used when large parameters are considered .To view output download QGIS 3.8.1 and run csv.

ABSTRACT

This study emphasizes the crucial role of efficient control techniques for output voltage and current in electric vehicle wireless charging systems. The research introduces a novel approach incorporating an interleaved Boost converter (IBC) and a solenoid coupler (SC), showcasing significant reductions in primary currents and losses. Facilitating closed-loop regulation between the input and output involves fine-tuning the IBC's pulse duration. The hardware configuration, complemented by a systematic parameter optimization method, enhances overall system efficiency by lowering ripple in the input current. Noteworthy results from the study include the achievement of an 84V output from a 15V DC supply at a power transfer distance of 17 cm. This strategic configuration not only contributes to reducing ripples in the input current but also advances the state of electric vehicle wireless charging technology.

INTRODUCTION

Wireless power transfer, or WPT, makes it possible to transmit electrical energy across substantial air gaps, offering distinct advantages in terms of flexibility, convenience, and safety. This innovative technology addresses and mitigates many of the drawbacks associated with conductive power transfer.[1]-[3].It can be used in multiple domains, including as implanted medical devices, automated undersea vehicles, and electric cars. The

adaptability and safety features of WPT make it a promising solution for diverse and emerging technological applications.[4]-[6].

The rapid proliferation of electric vehicles (EVs) in recent years has underscored the need for innovative advancements in the corresponding charging infrastructure. Wireless charging systems for electric vehicles have acquired significant focus due to their convenience and potential to transform the EV user experience. However, challenges persist, particularly in optimizing control techniques for output voltage and current. Existing configurations often encounter issues related to primary currents, losses, and input current ripple, necessitating a fresh approach for enhanced efficiency. In response to these challenges, this research project explores a novel methodology integrating an Multiphase Boost converter and a solenoid coupler (SC).

Maintaining a steady output voltage/current is necessary to maximize the performance of a wireless power transfer, or WPT, system and guarantee the service life of a load. But the output is very dependent on the alignment of the transmitters (Tx) and receivers (Rx). According to the MIC approach, which is the basis for this inquiry, Wireless Power Transfer (WPT) can be accomplished by creating a magnetic field between a transmitter coil and a receiver coil. Based on the concepts of electromagnetic induction, this technique transfers energy without the need for physical connections by causing an alternating voltage in the transmitter's coil to induce a similar voltage in the reception coil. [7]-[12].

Phase shift control, when implemented through a full bridge inverter, has the capability to maintain system resonance. However, its practical application is constrained by drawbacks like low inverter gain and a limited adjustment range, hindering its effectiveness.[13]. To overcome these limitations, The research proposes an innovative solution by advocating the substitution of the Inverter with four quadrants and an IBC. The alteration is intended to increase the adjustment range by increasing the inverter gain. The heightened inverter gain leads to an increased output voltage, decreased current, and decreased primary losses. The Multiphase Boost Converter not only enhances the system by minimizing ripple in the DC input current but also plays a crucial role in mitigating the the WPT system's effect on the electrical grid.

These are the principal contributions of this work. Initially, the introduction of the interleaved Boost converter (IBC) results in reduced input current ripple, heightened system

efficiency, and a more compact receiver size for the wireless power transfer (WPT) system. Modifying the duty cycle of the IBC enables control over the output voltage of the proposed WPT system, eliminating the need for the DC-DC converter typically found in the secondary side of a traditional WPT system. This reduction contributes to a lighter and smaller receiver. The decrease in primary side currents and the increase in DC bus voltage further enhance the system's overall efficiency. The interleaved structure significantly diminishes the ripple in the input current, thereby mitigating the adverse impacts of the WPT system on the electrical grid.

LITERATURE SURVEY

The rise in Electric Vehicles (EVs) and charging stations has increased distortion issues in power quality, affecting harmony and voltage integrity. This impacts renewable energy systems like wind and solar, and smartgrid transmission networks. It's crucial to address these challenges for efficient EV adoption and renewable energy integration. [14]

Energy-harvesting networks struggle with the variability of clean energy sources, impacting reliable mobile traffic delivery. Cellular networks aiming to minimize grid energy use and integrate renewables face a proven NP-hard optimization problem. Addressing this challenge is vital for improving the efficiency of renewable energy integration in networks. [15]

Rapidly charging EV's at peak load can surpass safe voltage thresholds in low voltage distribution networks, requiring mitigation for sustainable integration. [16]Wireless charging for EV while driving could reduce energy conservation needs, addressing range anxiety and cost concerns. This innovative approach has the potential to revolutionize electric vehicle technology and enhance their practicality for widespread adoption. [17]

EXISTING METHOD

Fig.1.Circuit model of Existing System

Fig.1 shows the circuit model of existing system. The boost inverter circuit comprises two Boost converters: the first one consists of Q1, and Q3, while the second one includes Q2, and Q4. The equivalent impedance of the post-stage circuit is denoted as Z. The duty cycle (D) of the boost inverter, defined as the proportion of the duration during which Q3 and Q4 are ON to the entire period, falls into three categories: (1) D is less than 0.5, (2) D equals 0.5, and (3) D exceeds 0.5. Q4 lags Q3 by half the period, and the conduction of Q1 and Q3, as well as Q2 and Q4, is complementary. The volt-second balance concept underlies the circuit's operation. The boost inverter may lead to a larger receiver size, compromising the system's overall compactness and portability. Furthermore, the system efficiency could be adversely affected, as the boost inverter may lack the capability to provide high inverter gain, resulting in lower output voltage and the potential for increased currents and losses on the primary side. The boost inverter may introduce higher ripple in the DC input current, posing challenges for system stability. Due to the absence of the ability to regulate output voltage, the BI requires the retention of a voltage converter on the auxiliary side of the WPT system. This necessity contributes to a heavier and less efficient receiver, ultimately limiting the practicality and overall performance of the mechanism for wireless power transfer.

CIRCUIT ANALYSIS OF EVWC

SOLENOID COUPLER

Fig 2. solenoid coupler.

The operation of the solenoid is illustrated in the provided Figure 2. Solenoid is a type of electromechanical device that is composed of a wire coil wrapped in a helical shape around a cylindrical or a straight core. When an electric current is passed through the coil, it creates a magnetic field. Solenoids are commonly used in various applications for their ability to convert electrical energy into linear motion or to produce a magnetic field. The fields of magnetic attraction are created by electric currents that travel through coils. The core moves into or out of the coil as a result of a force generated by the magnetic field.[18]

INTERLEAVED BOOST CONVERTER

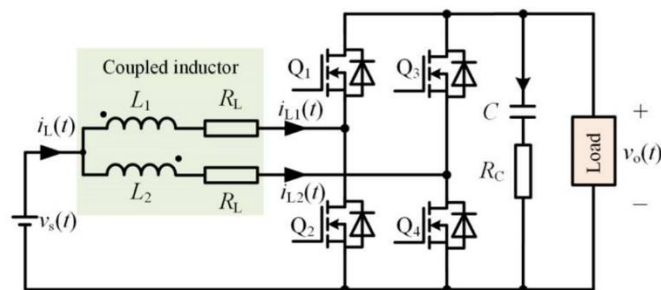

Fig 3. Interleaved Boost Converter

The circuitry of the Interleaved Boost Converter (IBC) is depicted in the Figure 3 above for observation. Interleaved Boost Converters (IBCs) reduce input current ripple effect, enhance system efficiency, and result in a more compact recipient when integrated into Wireless Power Transfer (WPT) systems. The voltage that comes out of the suggested WPT

system can be efficiently controlled by varying the pulse duration of the IBC, doing away with the requirement for a secondary side DC-DC converter in a traditional WPT configuration. This streamlining results in a cheaper and more compact receiver unit. The overall system efficiency benefits from the boosted DC bus voltage, leading to reduced currents on the primary side. The interleaved structure of the IBC contributes to a significant reduction in input current ripple, thereby minimizing the WPT system's impact on the power grid. The typical EVWCS transmitter tends to be sizable with a considerable number of turns, leading to a higher equivalent series resistance (ESR). To enhance system efficiency, it proves beneficial to decrease the current passing through the transmitter, effectively reducing losses. Boost inverter use makes it possible to raise the voltage of the DC bus, resulting in a lowered current through the transmitter. In essence, the boost inverter contributes to an efficiency improvement by minimizing transmitter losses.[19]

STEP DOWN TRANSFORMER

Fig 4. Stepdown Transformer.

One essential part used to lower voltage from the main winding to the other winding is a transformer with a stepdown function. The main coil has more turns than the coil that is secondary as shown in fig4. In order to accomplish this voltage reduction, following a specified turns ratio. Commonly employed in power distribution networks, these transformers play a vital role in converting high-voltage electricity transmitted over long distances into lower, safer voltages suitable for homes, businesses, and industries. With their ability to provide electrical isolation between primary and secondary circuits, Buck Transformers ensure safety and protect devices on the secondary side. The transformers consist of coils wound around a magnetic core, contributing to efficient magnetic flux

transfer. Widely used in household electronic devices, Buck Transformers contribute to the efficient and safe operation of various appliances, maintaining high levels of efficiency and reliability.[20]

PIC CONTROLLER

The PIC 16F84A microcontroller's pin diagram can be observed in fig.5. It is integrated into one structure that is used to transfer commands from the processor to the features using the reduction in the frequency range approach. The Harvard architectural type microcontroller is an 8-bit device with an 18-pin Programmable Double consistent Package and a Reduced Instruction Set Computer (RISC) processor.

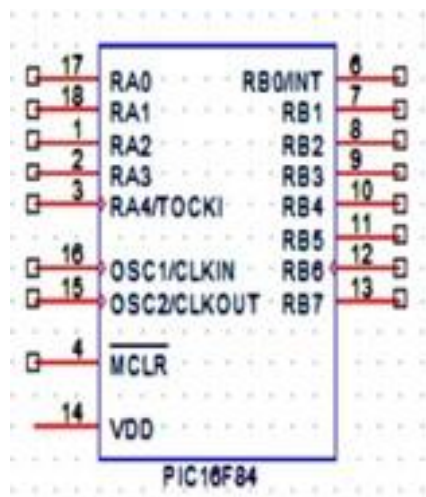

Fig 5. PIC Controller

The types of IC are: 1. PDIP- Programmable Dual in-line Package, 2. SOIC-Small Outline IC, and 3. SSOP-Small Shrink Outline Package. The PIC 16F84A microcontroller has two bi-directional ports. They are Port-A and Port-B. Port-A has 5-pins RA0, RA1, RA2, RA3, RA4 and Port-B has 8-pins RB0, RB1, RB2, RB3, RB4, RB5, RB6, RB7. The Ports RA0, RA1, RA2, RA3 are used as a output ports.[21] ‘

PROPOSED SYSTEM

Fig 6 . Circuit Diagram of Proposed System

In Fig.6, the proposed Electric Vehicle Wireless Charging System (EVWCS) schematic circuit is depicted. U_{in} represents the DC input voltage, with C_{in} serving as the voltage-stabilizing capacitor, referred to as DC bus voltage (U_{Cin}) in this study. L_1 and L_2 , along with Q_1Q_4 , form an interleaved Boost converter functioning as both a booster of U_{in} to U_{Cin} and a full bridge inverter converting U_{Cin} to the voltage of square waves at high frequency U_{AB} . It is now referred to as a boost inverter. M is the mutual inductance, L_P and L_S are both the main and secondary self-inductances of the magnetic coupler, and C_1 and C_2 are the primary and secondary series compensation capacitors. R is the resistive load, C_F is the filtering capacitor, and D_1 – D_4 are the diodes.

CONTROL CIRCUIT

The controller circuit for a redesigned converter circuit intended for executing a hardware module is depicted schematically in Fig. 7. The PIC 16F84A microcontroller's architecture is consolidated into a single structure hardware module. Applying an unregulated 15v input to the 7812 regulator results in a regulated 12 V output from Pin-3. This 12 V enabling the reduction in frequency field technique.

from the CPU to different aspects to enable instruction pipelining. This microcontroller uses a Reduced Instruction Set Computer (RISC) processor and is designed in the Harvard architecture. With thirteen bidirectional ports, an eight-bit timer or counter with a prescaler, a high-current sink or source for LED driving, and a clock input speed of twenty millimeters per second, its eight-bit design fits inside an eighteen-pin programmable Dual In-line Package (PDIP). The hardware unit contains the circuits for power and control. The control circuit consists of the microcontroller, driver, and power supply. The PIC 16F84A microcontroller's architecture integrates various elements into a unified structure, including the free run counter, RAM, EEPROM, flash memory, port-A, port-B. Special features of the microcontroller include power-on reset, In-circuit serial programming, watchdog timer, code protection, power-saving sleep mode, and selectable oscillator options.

POWER SUPPLY UNIT

Fig.8..Schematic diagram of Power supply unit.

The figure depicts the power supply unit for an interleaved boost converter as illustrated in Figure 8. The IC 7812 Voltage Regulator is a three-pin device, where Pin-1 serves as the input, Pin-2 as ground, and Pin-3 as the output. In this series voltage regulator, the "78" denotes a positive supply, and "12" signifies an output voltage of 12 V. Similarly, the IC 7805 Voltage Regulator has Pin-1 as input, Pin-2 as ground, and Pin-3 as output, producing a 5 V output. Both 78XX versions can generate output voltages within the range of +5V to +24V. When combining the 7812 and 7805 voltage regulators in series, the common ground is established by connecting pin-2 from both regulators. output is then used as input to the Pin-1 of the 7805 regulators. The 7805 regulator produces a 5V output at Pin-3. The voltage differentials between input and output can be adjusted by varying the input voltage sufficiently to maintain proper IC operation. The common grounding of Pin-2 from both regulators ensures stability. The node point between Pin-3 of the 7812 regulator and Pin-1 of the 7805 regulator, providing 12 V, serves as input for the the IR2110 driver IC. The 7805 regulator's 5V output is simultaneously used as the microcontroller's input. The 7812 regulator is supplied with an unregulated 15 V input at Pin-1, producing a regulated 12 V output at Pin-3. The 12 V output from Pin3 serves as the input to the 7805 regulator. The 7805 regulator, in turn, provides a regulated 5 V output at Pin3. The Pin-2 of both the 7812 and 7805 regulators is commonly grounded. The node point between the Pin-3 of the 7812 regulator and the Pin-1 of the 7805 regulator, carrying the 12 V, is utilized as the input for the IR2110 driver IC. The 7805 regulator's 5V output is simultaneously used as the microcontroller's input. This configuration ensures proper operation by maintaining the necessary voltage drop across the ICs, with their Pin-2 terminals commonly grounded.

A Buck Transformer is utilized to reduce the 230V AC supply to 15V AC. The transformer's output is linked to a Bridge Rectifier Circuit to convert the AC supply to DC, and a capacitor is incorporated to minimize voltage ripples. This stabilized 15V is employed as a power supply for the IBC. The IBC, housing MOSFETs connected in parallel to an inductor, requires a gate pulse for MOSFET operation, supplied by the control circuit. The IBC produces a DC output, subsequently transformed back to AC by a Boost Inverter. The IBC enhances inverter gain, resulting in higher output voltage, smaller currents, and reduced primary losses. Positioned on the transmitter side, the IBC is linked to a solenoid, and power

transfer occurs through Magnetic Inductive Coupling. Applying voltage to inductors generates a Fluctuating Magnetic Field, inducing EMF in the solenoid on the receiver side. The solenoid output is corrected using a Bridge Rectifier Circuit, converting AC to DC. This DC voltage is then employed to charge the electric vehicle (EV) battery. The proposed method yields an output of 80V for a 14V input, achieving a sixfold increase in voltage.

Fig 10. Simulation results of the I_{in} , I_{L1} and I_{L2} of a BI when a) $D < 0.5$, b) $D = 0.5$, and c) $D > 0.5$.

The periodic charging and discharging of the voltage- decoupling capacitor C_{in} in the FBI lead to a significant ripple in the input current, impacting the power grid. Utilizing a BI can help alleviate this problem. Figure 10 illustrates the Inductor currents and input current (I_{in}) of a BI under various duty cycle scenarios. The sum of I_{L1} and I_{L2} equals I_{in} , and due to their interleaved arrangement, the ripples in I_{L1} and I_{L2} counteract each other, resulting in minimal I_{in} ripple. This effect is particularly pronounced when the duty cycle is 0.5, where the I_{in} ripple is effectively reduced to zero.

Fig 11. output of Driver Circuit

A 5V gate pulse is supplied by the PIC Microcontroller to the driver circuit. The driver circuit functions as a signal amplifier, elevating the 5V gate pulse to 10V. The result of the driver circuit is depicted in Figure 11. This amplified output is subsequently employed to drive the MOSFET in the IBC.

Fig 12.voltage waveform on Transmitter side

Fig 13. voltage waveform on receiver side

In Figure 12, the voltage on the transmitter side, specifically the voltage supplied to the Isolated Boost Converter (IBC), indicates a lower input voltage. Conversely, Figure 13 illustrates the output voltage of the IBC, revealing a higher output voltage. Notably, the interleaved structure of the Boost Inverter is evident in both input and output voltages, contributing to a discernible reduction in ripples. This design feature enhances the overall stability and performance of the system, ensuring more consistent and reliable voltage levels.

Fig 14. Input Voltage

Fig 15. Output dc voltage

The suggested system's input and output DC voltages are shown in Figure 14 and Fig 15. A significantly high output voltage can be achieved through this innovative system. The Interleaved Boost Converter (IBC) in this configuration reduces losses in voltage and provides a substantial inverter gain. The proposed method yields an output of 80V for a 15V input, achieving a sixfold increase in voltage.

CONCLUSION

The Electric Vehicle Wireless Charging System (EVWCS) integrates key components, including an Interleaved Boost Converter (IBC) and a PIC 16F84A microcontroller-based modified converter circuit. Replacing the full bridge inverter with IBC enhances inverter gain, widening the adjustment range, resulting in higher output voltage, decreased losses and currents in the primary, improving overall efficiency. IBC also lowers the DC input current ripple, lessening the impact on the power grid. Compared to the existing system, IBC introduces a smaller, lighter receiver, contributing to a streamlined, efficient system with boosted DC bus voltage and reduced primary side currents, significantly lowering input current ripple. However, challenges arise, notably misalignment tolerance between transmitter and receiver. Future work involves implementing methods like optimizing compensation topologies and modifying magnetic couplers to enhance misalignment tolerance in Wireless Power Transfer systems, aiming for improved overall performance.

Abstract

The IoT (Internet of Things) is a rapidly evolving technology that focuses on connecting devices or components to each other and to people. Over time, many of these connections have shifted from "Human to Device" to "Device to Device." Automatically detecting faulty streetlights has become a crucial milestone in leveraging this technology. The primary objective of this project is to enable the automatic control and identification of damaged streetlights. The lighting system aims to be energy-efficient and operate automatically at an economically affordable level for streets, providing immediate information about any faults in the streetlights. Traditionally, streetlight faults are identified through complaints from residents. However, in this proposed work, sensors are utilized to capture the working status of the lights without manual intervention. This approach significantly reduces manual efforts and minimizes the delay in addressing problems. To address this issue, we propose a solution where streetlight issues are automatically detected during night time. Notifications are then sent to authorized personnel indicating the specific streetlight that requires attention, along with its location. The streetlights are controlled automatically using IoT technology. The system constantly monitors whether the street lights are on or off. Utilizing an LDR sensor, the streetlights are automatically switched on or off based on the prevailing weather conditions.

INTRODUCTION

The realm of urban infrastructure, efficient street lighting plays a vital role in ensuring safety, security, and aesthetics. However, traditional street lighting systems often suffer from issues such as faults and failures, leading to disruptions in illumination and increased maintenance costs. In response to these challenges, the integration of Internet of Things (IoT) technology offers a transformative solution. By leveraging IoT-based street light fault detection and location tracking, municipalities and organizations can enhance the reliability, efficiency, and management of street lighting networks. IoT-based street light fault detection involves the deployment of sensors and communication modules within street light fixtures, enabling real-time monitoring of their operational status. These sensors can detect various faults, including bulb failures, wiring issues, and power fluctuations, among others. By continuously monitoring the health of street lights, maintenance teams can promptly identify and address any anomalies, minimizing downtime and ensuring uninterrupted illumination throughout urban areas. Moreover, the incorporation of location tracking capabilities enables precise identification of faulty street lights within the network. GPS or similar positioning technologies can pinpoint the exact geographic location of each street light, facilitating targeted maintenance efforts. This not only streamlines the maintenance process but also optimizes resource allocation, as maintenance crews can efficiently navigate to the site of the fault, reducing response times and enhancing overall operational efficiency. In essence, IoT-based street light fault detection and location tracking represent a paradigm shift in urban lighting management. By harnessing the power of IoT technology, municipalities and organizations can proactively monitor, manage, and maintain street lighting infrastructure, ultimately leading to safer, more sustainable, and better-lit urban environments.

RELATED WORK

Light Dependent Resistors (LDRs) play a crucial role in automatically switching streetlights on/off based on sunlight levels, resulting in numerous benefits such as adapting

to seasonal variations, increasing energy efficiency, and reducing operating and maintenance costs. The inclusion of Crozet Millennium software facilitates testing and analytics, ensuring precise functionality of streetlights. In a study by [18], a Street Light Observing and Controlling System, based on GSM technology, enhances organizational efficiency by automatically adjusting streetlights according to predefined schedules. This system comprises client-side and server-side modules, with a microcontroller interfacing with a GSM modem on the client-side and a Java-based web server on the server-side. The project's objective is to develop and implement an advanced streetlight control system to optimize power consumption. Utilizing LDRs and photoelectric sensors, the microcontroller PIC16F877A acts as the central processing unit, programmed in C language to control the streetlight system effectively.

Another innovative approach proposed in [20] involves RFID-based GSM streetlight systems, aimed at reducing power outage recovery time and facilitating maintenance and complaint management. This system not only conserves power but also streamlines the process of establishing new power connections through RFID technology. The overarching goal of automatic streetlight projects is to minimize manual intervention, thereby optimizing power usage. LDRs and sensors are essential components, ensuring lights are off during daylight hours and illuminating streets only when necessary. The adoption of intelligent street lighting systems, leveraging GSM technology and LED lamps, further enhances power conservation and responsiveness. The Intelligent Street Lighting (ISL) system represents a pioneering approach in public lighting systems, utilizing advanced technology to achieve flexibility and efficiency. In conclusion, automatic streetlight control systems offer a promising solution to minimize energy wastage and streamline operations. By leveraging microcontrollers, sensors, and advanced communication technologies, these systems contribute to building a more sustainable and efficient urban environment.

PROPOSED WORK

A system integrating a microcontroller, LCD display, voltage sensor, LED, current sensor, rectifier, transformer, IoT, and GPS holds great potential for smart and efficient monitoring of electrical systems. The microcontroller acts as the central processing unit, orchestrating the interaction between various components. The voltage and current sensors provide real-

time data on electrical parameters, enabling precise monitoring and analysis. The rectifier and transformer ensure stable power supply, contributing to the system's reliability. The LCD display serves as a user interface, offering a convenient way to visualize and interpret the collected data. Integrating IoT technology enables remote monitoring and control, allowing users to access information and manage the system from anywhere. GPS adds an extra layer of functionality, providing location-based data that can be valuable for tracking and managing distributed electrical systems.

Furthermore, the LED can be employed as an indicator to convey system status or to highlight critical events. This proposed system has the potential to find applications in various sectors, including industrial automation, smart grids, and energy management. With its ability to provide real-time data, remote accessibility, and location-based insights, the integrated system can enhance efficiency, reduce downtime, and facilitate proactive maintenance, contributing to a more sustainable and intelligent electrical infrastructure.

In our research on the Damaged Street Light Identification System, the primary focus is on reducing power consumption. Given the critical importance of energy in modern lifestyles, our goal is to create a prototype street lighting system to assess its effectiveness. This research encompasses insights from various sources, addressing different aspects of streetlight systems and the challenges associated with manual efforts. We discuss two key concepts and obtain unique and effective results. By integrating additional systems into the street lighting infrastructure, we aim to develop a research framework that is both efficient and cost-effective, accessible via the internet. The architecture of the proposed system divides it into two main components: the operation of streetlights and the transmission of information to authorized personnel. Raspberry Pi programming is utilized for streetlight control and fault detection via cloud storage. Unlike manual operation, where streetlights are typically controlled manually, our system automates these processes. LDRs are used to monitor ambient light conditions, determining whether streetlights should be switched on or off based on weather conditions.

A pivotal aspect of our system is the use of red LEDs to indicate faulty streetlights. When a fault is detected, a message containing the location of the damaged light is sent to the respective ward member or authorized person via Twilio. This message includes a URL specifying the exact location of the faulty light, determined through GPS coordinates. The

system architecture is designed using IoT principles, combining various sensors, software, cloud storage, and hardware components to create an efficient and responsive system. This aligns with the concept of smart cities, where technological advancements are leveraged to improve urban infrastructure and efficiency.

The system design includes real-time IoT-based control of streetlights and the development of a graphical user interface (GUI) for monitoring light status. Through experimental testing, we aim to optimize the system's performance and ensure efficient energy usage. Compared to traditional automatic streetlight systems, our approach offers energy savings of up to 8-10% by operating only during sunrise and set timings, and by adjusting to weather conditions. Moreover, it reduces the need for manual reporting by automatically alerting authorized personnel of faults and providing precise location information via URL links. illustrate the system architecture and data flow diagram, respectively, showcasing the seamless integration of sensors, LEDs, cloud storage, and communication technologies to enable efficient streetlight management and fault detection. Each streetlight is equipped with LDRs and red LEDs, which automatically trigger in case of faulty lamps, with GPS coordinates facilitating precise location identification. After repair, the red LED switches off automatically, indicating resolution of the fault.

intensity levels. Additionally, a comprehensive library of modules will be developed to replicate the various conditional parameters of the network, ensuring flexibility and scalability. A graphical user interface (GUI) will be designed to offer a user-friendly platform for monitoring the status of street lights. In comparison to traditional automatic street light systems, this advanced solution promises energy savings ranging from 8% to 10%, primarily achieved by operating the lights based on sunrise and present timings. Moreover, the system's adaptability to weather conditions reduces manual intervention, particularly during winter seasons.

One of the key advantages of the proposed system is its ability to swiftly identify and alert the respective authorized personnel regarding any faults in the street lights. This proactive approach not only streamlines the response process but also minimizes human effort in reporting issues. Fault alerts will include details about the specific light and its exact location, conveniently provided in the form of a URL. By selecting the URL, users can instantly view the precise location of the faulty light.

The system's continuous monitoring capabilities, facilitated by cloud-based infrastructure, ensure comprehensive coverage and real-time insights across all locations. The flow of the system, as depicted in Fig. 2, begins with the Light Dependent Resistor (LDR) checking the atmospheric light state. If the light state is already ON, no action is taken. However, if the light state is OFF due to weather conditions, the street lights are automatically activated. In the event of any lamp faults, the red LED attached to each street light will illuminate, signaling damage with the color red.

Each street light contains their respective LCD and red LED, this LCD is used to display the street light and ON the red LED automatically, in case of a faulty lamp. The location will send to the authorized person through the Think speak account. The Think speak Account is cloud storage, which stores the data. The description of the message and the mobile number of the authorized person is attached to this. At the time of fault detection, this message will send to that person. The exact location will be fetched through the GPS. These contains several forms of data, but in our project, we are using WIFI data which consists of longitude and latitude of the faulty light. After fixing the damaged lamp, the red LED will get OFF automatically.

The system architecture will encompass all components interconnected in a cohesive manner to facilitate data acquisition, processing, and presentation. The transformer and rectifier will convert alternating current (AC) to direct current (DC), ensuring stable power supply to the system. An IoT module will be integrated to enable connectivity to the internet, facilitating remote monitoring and control functionalities. GPS tracking capabilities, enhancing the system's utility in various applications.

RESULT AND DISCUSSION

Initially, a prototype was designed to assess the arrangement process of the entire system, serving as a foundation for future research and development endeavors. Following the prototype phase, the proposed system, as illustrated in Fig. 3, was developed and rigorously tested over several months to validate its real-time functionality. Our methodology yielded notable improvements in fault detection accuracy, coupled with the efficient automation of street light operations, resulting in significant energy savings.

In the first street light is depicted as OFF due to a detected fault. At this juncture, the red LED indicator is activated, signaling the fault. Conversely, in the event of successful street light activation, no further action is required. For experimental purposes, basic LEDs were employed in lieu of actual street lights.

Microcontrollers are used in automatically controlled products and devices, in a automobile engine control systems, implantable medical devices, remote controls, office machines, appliances, power tools, toys and other embedded systems. A liquid crystal display or LCD draws its definition from its name itself. It is a combination of two states of matter, the solid and the liquid. LCD uses a liquid crystal to produce a visible image. Liquid crystal displays are super-thin technology display screens that are generally used in laptop computer screens, TVs, cell phones, and portable video games. LCD's technologies allow displays to be much thinner when compared to a cathode ray tube (CRT) technology.

CONCLUSION

The implementation of an IoT-based street light fault detection and location tracking system represents a significant leap towards building smarter and more efficient urban landscapes. The fusion of advanced sensors, communication technologies, and fault detection algorithms creates a robust infrastructure capable of proactively identifying and addressing issues in real time. This transformative approach not only enhances the reliability of street lighting but also contributes to energy conservation and overall sustainability. By intelligently leveraging the power of IoT, cities can achieve a new level of responsiveness, ensuring that their street lighting networks remain operational, safe, and cost-effective.

Furthermore, the integration of location tracking adds a crucial layer of precision to the fault detection system. Knowing the exact location of a malfunctioning street light enables rapid response teams to streamline maintenance efforts, reducing downtime and ensuring the continuous functionality of the urban lighting grid. This capability is paramount for creating safer environments, improving visibility, and bolstering the overall quality of life for residents.

Ultimately, the IoT-based street light fault detection and location tracking system encapsulates the essence of a forward-thinking urban infrastructure. By harnessing the potential of interconnected technologies, cities can usher in an era where the lighting network becomes a dynamic and responsive component, contributing to the overall resilience and sustainability of urban environments. As these systems evolve, the promise of safer, more efficient, and energy-conscious cities comes to the forefront, highlighting the transformative impact of innovative IoT solutions on our daily lives.

Abstract

The abstract for the project “Android Based Child Monitoring Application using Smartwatch and Geofence Service” could be: This project proposes the development of a child monitoring application for Android devices, utilizing smartwatches and geofencing technology. The application aims to enhance child safety by providing real-time location tracking and geo-fencing features. Parents can monitor their child’s location through the smartwatch paired with the application, receiving alerts when the child enters or exits predefined safe zones. The Application also includes additional features such as emergency alerts, SOS button, and communication between the parent and child devices. The implementation of this application offers a comprehensive solution for parents to ensure the safety and security of their children.

INTRODUCTION

The introduction of an Android-based child monitoring application using a smartwatch and geofence service could be, ensuring the safety and well being of children has become a paramount concern for parents and caregivers. With the advancement of technology, especially in the real of wearable device and location-based services, new opportunities have emerged to address these concerns effectively.

The proposed application aims to leverage the capabilities of smartwatches and geofence services to create a comprehensive child monitoring solution. By utilizing a smartwatch worn by the child, the application can track their real-time location and activities. Geofence technology allows the application to setup virtual boundaries, ensuring that children stay within safe zones predefined by their parents or guardians.

The key features of the application include real- time location tracking, geofence alert, SOS notifications, and activity monitoring. Parents can receive notifications on their smartphones if their child enters or leaves a designated area, providing them with peace of mind and enabling them to respond quickly to any potential safety concerns. Overall, the android- based child monitoring application offers a robust and reliable solution for parents and caregivers to keep track of their children's whereabouts and ensure their safety in an increasing digital world.

You can use it to create interactive objects, such as robots, lights display and much more.

MINI A8 GPS

The MINI A8 GPS tracker is a small, portable device that uses GPS technology to determine its precise location. The device usually has a built-in SIM card slot and requires a SIM card with a data plan to transmit its location data to a server or mobile app.

TEMPERATURE SENSOR

There are various types of temperature sensors available, but one commonly used in hobbyist and DIY projects is the DS18B20 digital temperature sensor. It's suitable for measuring temperatures in a wide range, from -55°C to +125°C (-67°F to +257°F).

ACCELEROMETER SENSOR

The accelerometer sensor in a device measures acceleration, allowing the device to detect changes in orientation. It's commonly used in smartphones for features like screen rotation and step counting. The accelerometer tracks the child's movement or detects if the device has been picked up or moved.

GSM

GSM, or the Global System for Mobile Communications, is a standard developed by the European Telecommunications Standards Institute (ETSI) to describe the protocols for Second generation (2G) digital cellular networks used by mobile devices.

VOICE SENSOR

A voice sensor is a device that detects sound or voice and converts it into an electrical signal. It's commonly used in various applications such as speech recognition, security systems, and voice-activated devices.

DRAWBACKS IN EXISTING SYSTEM

- The systems are not atomized
- The child cant able to understand the awareness of the technology
- Complex system and difficult to operate

EXISTING METHOD

A lot of technologies already exist for body area sensor networks. However, wired technologies are difficult to use in this application and are impractical for long-term, minimally obtrusive residential monitoring. Furthermore, wired connections may be impossible if the sensors are implanted within the body. On the other hand, wireless technologies that use RF (such as Bluetooth and WiFi) suffer from these problems.

OBJECTIVES

- The specialist staying at a distance can monitor the child condition so that he can save the life of the patient using smart watch.
- This system is to be available at reasonable prices.
- IOT technology is to be use so that we can monitor the child condition easily using smart band.
- Supporting the child's learning and development by monitoring their educational activities and providing appropriate resources and support.
- Monitoring the child's health and well-being, including tracking their physical activity, sleep patterns, and ensuring they have access to healthcare when needed.

PROPOSED SYSTEM

- There are mainly two parts of the system one is IOT and Wearable SENSORS for smart watch.
- The system also makes it easier for parents, carers, and educational institutions to collaborate and communicate with one another, ensuring that child safety is taken seriously.
- The IoT-based kid Safety Monitoring System provides improved parental control, customization, and customization to cater to the unique demands of every family or kid.
- Even when parents are physically apart from their child using video cam attached to the watch and it send notifications to parents via SMS using GSM.
- IOT Based wearable health monitoring system is designed using IOT technology.
- Which consist of physiological sensor and a Wearable Hub (WH).
- Health data's such as Temperature, Heart rate Voice activity, motion and moisture collected by an inter-body from wearable physiologic sensor is hub using Smart band.
- when there is any abnormality in the child condition then he can monitor the situation using smart band

ADVANTAGES OF PROPOSED SYSTEM

- Real-time Monitoring: Parents can track their child's location, activity, and health status in real-time, providing peace of mind.

- **Emergency Response:** In case of emergencies, such as a child getting lost or in danger, parents can quickly locate them and take necessary actions.

RESULT

Overall, the system aims to provide parents with peace of mind by allowing them to monitor their child's location and health in real-time and receive alerts in case of emergencies or when the child enters or leaves designated.

CONCLUSION

The project IOT based child monitoring system has been successfully designed and tested .It has been developed by integrating features of all the hardware component used. They also offer parental controls and activity tracking, promoting a healthy and safe environment for children. Overall, smartwatches serve as an effective tool for parents to monitor and protect their children, providing peace of mind and ensuring their safety in various situations.

ABSTRACT

The electric scooter designed for blind people would be to provide safe and accessible mobility option Accessibility that are incorporating tactile markers or braille instructions to help blind users navigate controls and settings. Safety to Implementing obstacle detection and avoidance systems using sensors or cameras to alert the rider of potential hazard .Stability that Designing the scooter with a low center of gravity and sturdy construction to enhance stability and prevent tipping system. Auditory Feedback is providing audible cues and feedback for speed, direction changes, and battery level to assist users in understanding their surroundings. Easy operation to simplifying controls and interfaces for intuitive operation, possibly through voice commands or haptic feedback. Long life of the battery is ensuring sufficient battery range for extended use, considering that users may rely heavily on the scooter for transportation. Comfort on Prioritizing ergonomic design and comfortable seating to accommodate users during longer rides. By designing an EV scooter with features tailored to the needs of blind individuals, such as advanced obstacle detection systems, audible alerts, and easy-to-use interfaces. Electric scooters are the future of this world as they produce zero emissions, making them an eco-friendly transportation option. They also are quieter than gas-powered vehicles, reducing noise pollution in urban environments and making for a more pleasant riding experience.

INTRODUCTION

GENERAL INTRODUCTION

Blind mobility is one of the main challenges that scientist are most widely used travelling aid used by all blinds is the white cane. It has provided those people with a better way to reach destination and detect obstacles on ground, but it cannot give them a high guarantee to protect themselves and being away from all level of obstacles. The recent advances in assistive technology it is possible to extend the support provided to blind people taking into consideration the support provided to blind people taking into consideration the concept of the white cane. Historically, there are various types of assistive technologies that are currently available to blind or visually impaired people. Thus, the distance to the obstacle is calculated according to the time variance between the to signals. Wearable and portable assistive technologies are also used for assisting people with disabilities such as the blind. Wearable devices are allowed hands-free interaction, or at least minimizing the use of hands when using the device, while portable assistive device required a constant hand interaction. Despite efforts and the great variety of wearable assistive devices available, user acceptance is quit low and the white cane will continue to be the most assistive devices for the blind. On the other hand, to enhance the means that assist blind persons to navigate quickly and safely in an unfamiliar environment, various projects were introduced using different technologies like PIR Sensor, Ultra sonic sensor, Gyroscope sensor and Raspberry pi. Passive infrared sensor [PIR] is an electronic sensor used in motion detectors such as automatically triggered lighting devices and protection systems that measure devices emitting infrared light in their field. It is commonly used in security alarms and automatic lighting applications. Ultra-sonic sensor is an electronic device that measures the distance of a target object by emitting ultrasonic sound waves, and converts the reflected sound into an electrical signal. It is a non-

contact type of sensor used to measure an object distance and velocity. Gyroscope sensor, also known as angular velocity sensors, can detect changes in rotation angle per unit of time.

This make it possible to detect quantities such as the direction of rotation, rotation angle, and vibration. Raspberry pi to learn programming skills, build hardware. Passive infrared sensor (PIR sensor) that measures infrared (IR)light radiating from objects in its field of view. An Indian electric two-wheeler manufacturer, headquartered in Bangalore. It was founded by Tarun Mehta and Swapnil Jain in 2013. It currently manufactures electric scooters known as the Ather 450 Apex, Ather 450S, Ather 450X and the Ather 450X Pro.

The chief architect was N.H.Raj Kumar who is the first indigenously designed and built vehicle in India. Project Atlanta or the Atlanta scooter was the spark that was lit in the mind of this engineering genius. Born to Dr V Nagoji Rao and Yamuna Rao at Thalassery in Kannur, Raj Kumar studied in Vaikom and Mavelikkara.A scooter (motor scooter) is a motorcycle with an underbone or step-through frame, a seat, a transmission that shifts without the operator having to operate a clutch lever, a platform for the rider's feet, and with a method of operation that emphasizes comfort and fuel economy. In 1915, the first motorized scooters hit the streets of New York City with the release of the Autoped. These mass-produce scooters had a gas-powered engine affixed over the front wheel and reportedly reached a wobbly 30 mph.

BLDC MOTOR

Innovative Electric Vehicle (EV) Accessibility for Individuals with Visual Impairments entails the integration of advanced technologies, including Brushless DC (BLDC) motors, to revolutionize mobility solutions. BLDC motors offer numerous advantages over traditional brushed motors, such as higher efficiency, lower maintenance requirements, and enhanced controllability, making them an ideal choice for electric vehicles designed to cater to the unique needs of visually impaired individuals.

By incorporating BLDC motors into EVs tailored for this demographic, we are paving the way for safer, more reliable, and accessible transportation options. These motors enable precise speed control, smoother acceleration, and quieter operation, thus enhancing the overall user experience for individuals with visual impairments. Moreover, their compact

size and lightweight design contribute to the development of more maneuverable and space-efficient vehicles, further optimizing accessibility in urban environments.

At conferences focusing on innovation in electric mobility and accessibility, showcasing the utilization of BLDC motors in EVs for individuals with visual impairments underscores the commitment to inclusivity and technological advancement in transportation. It highlights a collaborative effort among engineers, designers, and accessibility advocates to create solutions that empower individuals with disabilities and promote greater independence and mobility for all. Through continued research, development, and collaboration, we can further advance the integration of BLDC motors and other cutting-edge technologies to enhance accessibility and inclusivity in electric transportation systems.

SENSORS

A sensor is a device that detects and responds to some type of input from the physical environment. The input can be light, heat, motion, moisture, pressure or any number of other environmental phenomena. The output is generally a signal that is converted to a human-readable display at the sensor location or transmitted electronically over a network for reading or further processing. Sensors play a pivotal role in the internet of things (IOT). They make it possible to create an ecosystem for collecting and processing data about a specific environment so it can be monitored, managed and controlled more easily and efficiently. IoT sensors are used in homes, out in the field, in automobiles, on airplanes, in industrial settings and in other environments. Sensors bridge the gap between the physical world and logical world, acting as the eyes and ears for a computing infrastructure that analyzes and acts upon the data.

The range of sensor technologies to enhance usability and safety. These sensors primarily fall into three categories: proximity sensors, ultrasonic sensors, and PIR sensors.

Proximity sensors play a crucial role in detecting nearby obstacles or objects, alerting the driver or user of potential hazards. These sensors emit electromagnetic fields or beams and can detect the presence of objects within their range without physical contact. By integrating proximity sensors strategically around the electric vehicle, individuals with visual impairments can navigate their surroundings more confidently, receiving real-time feedback about obstacles in their path.

Ultrasonic sensors, similar to proximity sensors, emit sound waves and measure their reflection to determine the distance to nearby objects. These sensors are particularly useful for detecting objects at varying distances and can provide valuable information about the environment's layout. By incorporating ultrasonic sensors into the EV's design, individuals with visual impairments can receive detailed spatial information, helping them maneuver safely and efficiently.

At the forefront of this solution are PIR (Passive Infrared) sensors, which play a pivotal role in revolutionizing the interaction between individuals with visual impairments and EVs. These sensors are strategically integrated into the design of EVs, enabling them to detect the presence of individuals in their vicinity without requiring physical contact. By leveraging PIR technology, EVs can provide real-time feedback and assistance to individuals with visual impairments, facilitating safer navigation around the vehicle and promoting greater independence in transportation. This innovative application of PIR sensors represents a significant step forward in inclusive design for EVs, fostering a more accessible and equitable mobility experience for all individuals, regardless of visual ability. This topic promises to ignite insightful discussions and pave the way for further advancements in the field of assistive technology at conferences and symposiums focused on accessibility and innovation.

PIR sensors detect general movement, but do not give information on who or what moved. For that purpose, an imaging IR sensor is required. PIR sensors are commonly called simply "PIR", or sometimes "PID", for "passive infrared detector". The term passive refers to the fact that PIR devices do not radiate energy for detection purposes. They work entirely by detecting infrared radiation (radiant heat) emitted by or reflected from objects.

Overall, the combination of proximity sensors, ultrasonic sensors, and PIR sensors in Innovative EV Accessibility for Individuals with Visual Impairments ensures enhanced safety and usability, empowering users to navigate their surroundings with greater independence and confidence. These sensor technologies represent a significant advancement in making electric vehicles more inclusive and accessible for individuals with visual impairments.

This paper is organized as follows; hybrid DG system configuration is introduced in Section II and paradigms of the approach for islanding and PQ disturbance detection is given

in Section III. Then, the simulated results and discussions on performance of detection methods are described in Section IV, followed by conclusions drawn from Section V.

CONSTRUCTION OF SYSTEM

The visual impairments involves the integration of various design elements and technologies to ensure safe and convenient transportation experiences.

One key aspect is the incorporation of tactile indicators and braille signage within EV charging stations and vehicles, allowing visually impaired users to easily locate and navigate the charging infrastructure. The Innovative Electric Vehicle (EV) Accessibility for Individuals with Visual Impairments is two parts on below,

1. Hardware
2. Software

HARDWARE

BIKE MODEL

The modified bike model is powered by DC 6-12V 300 RPM Gear Motor High Torque. This bike model uses one BLDC motor to control the steering angle of the car model. This bike model employs Arduino to control its speed and steering angle by giving the command to the DC motor and micro servo motor. The BLDC motor's simpler commutation method allows a wide range of our products to be used to control it, from 8-bit PIC and AVR micro controllers to the MTD650x family of dedicated BLDC drive chips, to advanced ds PIC digital signal controllers and PIC32MK and SAM Arm Cortex-M0. A brushless DC electric motor (BLDC), also known as an electronically commutated motor, is a synchronous motor using a direct current (DC) electric power supply.

BATTERY

The lead-acid battery is a type of rechargeable battery first invented in 1859 by French physicist Gaston Plants. It is the first type of rechargeable battery ever created. Compared to modern rechargeable batteries, lead-acid batteries have relatively low energy density. Despite this, their ability to supply high surge current means that the cells have a relatively large power-to-weight ratio. These features, along with their low cost, make them attractive for use in motor vehicles to provide the high current required by starter motors.

As they are inexpensive compared to newer technologies, lead-acid batteries are widely used even when surge current is not important and other designs could provide higher energy densities.

In 1999 lead-acid battery sales accounted for 40-50% of the value from batteries. By 2001, Chloride had divested itself of its last remaining battery subsidiary and the non-core Safety Systems operations in the UK and USA to better focus on the fast-growing market of Power Protection. A global leader in designing, manufacturing, and servicing industrial UPS systems

Ampere hours -- sometimes abbreviated as Ah or amp hours -- is the amount of energy charge in a battery that enables 1 ampere of current to flow for one hour. Another way of saying it is that 1 Ah is the rating indicating how much amperage a battery can provide for one hour.

Batteries from manufacturer Optima, for example, come with a three-year warranty plan if they're used by what the brand refers to as normal consumers. Commercial vehicle buyers, however, only receive a one-year warranty because they typically put more strain on a battery.

Chloride Exide is an energy solutions provider that provides: automotive batteries; and through Chloride Solar it provides energy storage solutions; solar energy solutions and water heating solutions.

SOFTWARE

RASPBERRY PI 4 MODEL B AND RASPBERRY PI CAMERA

The Raspberry Pi 4 Model B and Raspberry pi Camera represent a powerful combination of hardware for creating innovative solutions, particularly in the realm of accessibility for individuals with visual impairments. The Raspberry Pi 4 Model B serves as a versatile and cost-effective computing platform, offering ample processing power and connectivity options. Its compact size and low power consumption make it ideal for embedding into various devices and systems. Processor speed ranges from 700 MHz to 1.4 GHz for the Pi 3 Model B+ or 1.5 GHz for the Pi 4; on-board memory ranges from 256 MB to 8 GB random access memory (RAM), with only the Raspberry Pi 4 and the Raspberry Pi 5 having more than 1 GB.

Complementing the Raspberry Pi 4, the Raspberry pi Camera provides high-quality imaging capabilities in a small form factor. With features such as high-resolution still images and video capture, along with support for various add-on lenses and accessories, the Raspberry pi Camera offers flexibility for capturing visual information in diverse environments.

When integrated into accessibility-focused projects, the Raspberry Pi 4 and Raspberry pi Camera can enable a range of functionalities to aid individuals with visual impairments. For example, the Raspberry pi Camera can be used to capture images of the surroundings, which can then be processed by the Raspberry Pi to provide real-time feedback through audio cues or tactile interfaces. This setup could assist users in navigating unfamiliar environments, identifying objects, or detecting obstacles in their path.

Furthermore, the Raspberry Pi's programmability allows developers to implement custom software solutions tailored to the specific needs of users with visual impairments.

Whether it's developing applications for object recognition, scene description, or navigation assistance, the Raspberry Pi platform offers a flexible environment for creating accessible technologies.

Overall, the Raspberry Pi 4 Model B and Raspberry pi Camera combination presents a promising avenue for developing innovative accessibility solutions that enhance the independence and quality of life for individuals with visual impairments. By harnessing the capabilities of these versatile tools, developers can contribute to creating a more inclusive society where everyone can participate fully and equally.

VOICE COMMAND INTEGRATION

It involves integrating voice command functionality using Node MCU and a speaker system. By leveraging Node MCU, an open-source IoT platform based on the ESP8266 Wi-Fi module, and a speaker, EVs can be equipped with voice-controlled features tailored to the needs of visually impaired users.

Through voice commands, users can interact with various aspects of the vehicle, such as controlling navigation, adjusting climate settings, and accessing vehicle status information. Node MCU serves as the bridge between the vehicle's on board systems and the user's voice commands, facilitating seamless communication and control.

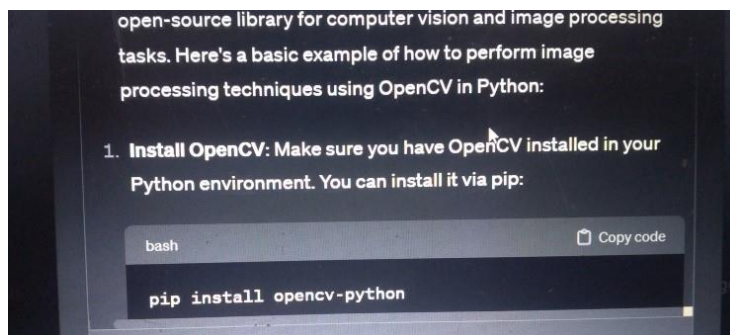

Additionally, the speaker system provides audible feedback to confirm user commands and provide necessary information, enhancing the user experience and ensuring accessibility for all individuals, regardless of visual ability.

This integration not only enhances the inclusivity of EVs but also showcases the potential of IoT technology to address accessibility challenges in transportation and beyond.

IMAGE PROCESSING METHOD

Image processing using OpenCV involves several steps to manipulate and analyze digital images. Firstly, you need to import the OpenCV library into your Python environment. Then, you can load an image from a file or capture it from a camera using OpenCV's built-in functions. Once the image is loaded, you can perform various operations such as resizing, cropping, and rotating using functions provided by OpenCV.

Next, you might want to apply filters or transformations to enhance or modify the image. OpenCV offers a wide range of functions for this purpose, including blurring, sharpening, edge detection, and colour manipulation. These techniques can be used for tasks like noise reduction, feature extraction, and object detection.

1. **Import Libraries:** Import the necessary libraries in your Python script:

```
python
import cv2
import numpy as np
```

1. **Read an Image:** Load an image using OpenCV's 'cv2.imread()' function:

```
python
image = cv2.imread('input_image.jpg')
```

Additionally, OpenCV provides tools for feature detection and image recognition, such as Haar cascades for face detection or SIFT and SURF for keypoint detection and matching. These techniques are essential for tasks like object tracking, facial recognition, and augmented reality applications.

1. **Saving Results (Optional):** You can save the processed images using 'cv2.imwrite()':

```
python
cv2.imwrite('output_image.jpg', thresholded_image)
```

Finally, after processing the image, you can display the results using OpenCV's visualization functions or save the modified image back to a file. Overall, OpenCV is a powerful tool for image processing, offering a comprehensive set of functions and algorithms for various applications, from basic operations to advanced computer vision tasks.

1. **Display Results:** Display the original image, grayscale image, thresholded image, and edge-detected image using OpenCV's 'cv2.imshow()' function:

```
python
cv2.imshow('Original Image', image)
cv2.imshow('Grayscale Image', gray_image)
cv2.imshow('Thresholded Image', thresholded_image)
cv2.imshow('Edges', edges)
cv2.waitKey(0)
cv2.destroyAllWindows()
```

CHARGING AND DISCHARGING

EV charging software enables EV charging operators and e-mobility service providers to manage all aspects of EV charging so they can maximize charger uptime and provide drivers with an exceptional EV charging experience. The software also enables monetization of

services for EV charging providers. a vehicle that can be powered by an electric motor that draws electricity from a battery and is capable of being charged from an external source.

All batteries degrade with time and use. Most EVs have a warranty for eight years or 100,000 miles, whichever is earlier. An EV battery is considered at end of its life if it no longer maintains 80% of total usable capacity and has more than 5% self-discharge rate over a 24-hour period (Engel et al. 2019). Accelerated battery degradation can be caused by charging and discharging patterns, such as repeatedly using the entire capacity of a battery, or repeated rapid charging (IEA 2020).

Charging and discharging patterns are measured via 'C-rates' per hour, so that 1C-rate means that the battery will be completely charged or discharged in 1 hour at that level of current. Ignoring the conversion efficiencies, the C-rate can be calculated by dividing the charger's power level by the battery capacity or size. For a given charging power, the larger the battery capacity, the lower the C-rate for charging

BENEFITS OF EV IN INDIA

By 2025, electric vehicle sales could comprise up to 20% of new car sales. By 2030, electric vehicle sales could reach 40% of new car sales. By 2040, electric vehicle sales could account for nearly all new car sales. The scope of Electric Vehicles in the future is exceptionally promising. As environmental concerns, technological advancements, infrastructure development, and policy support converge, EVs are set to become the mainstream mode of transportation.

Global EV marketing is growing at a staggering CAGR of 21.7%. A whopping 4.19 lakh EVs have already been sold in India in 2022. This number stood at a mere 1.19 lakhs in 2020. Studies predict a sale of 39.21 million EV units by the year 2021. The scope of Electric Vehicles in the future is exceptionally promising. As environmental concerns, technological advancements, infrastructure development, and policy support converge, EVs are set to become the mainstream mode of transportation. Indian EV market with a market share of 72%: Canalsys. Setting up EV charging stations in India is a profitable business that requires investment of ₹10-₹30 lakh and can earn revenue of ₹4- ₹5 lakh per month based on your services. Lower fuel costs: EVs are much more efficient than internal combustion engine (ICE) vehicles and require less energy to operate, resulting in lower fuel costs for drivers. Lower maintenance costs: EVs have fewer moving parts than ICE vehicles, which means they require less maintenance and are less likely to break down. Growing climate change concerns, coupled with technological advancements in the automotive industry, have fueled the growth of electric vehicles (EVs). In the first half of 2023, there was a 40% increase in global EV sales compared to the previous year. By 2030, EVs will constitute 35 to 40% of all new car sales.

CONCLUSIONS

E-scooters are more suitable for rural areas where the numbers of petrol bunks are not adequate, so that the rural people can charge the vehicle with the help of electricity. To understanding the EV technology, this study helps to provide outline of EV (Scooter) and there various components. electric scooters offer a multitude of benefits, making them an attractive choice for individuals seeking a convenient, eco-friendly, and enjoyable mode of transportation.

Electric vehicles (EVs) have a battery instead of a gasoline tank, and an electric motor instead of an internal combustion engine. Plug-in hybrid electric vehicles (PHEVs) are a combination of gasoline and electric vehicles, so they have a battery, an electric motor, a gasoline tank, and an internal combustion engine.

As per a report, the global sales of electric scooters and bicycles are expected to reach 129 million units by 2028. In 2019, the electric scooters sales was near 46.89 44.39, which grew to 50 in 2020. This gradual growth tells us the incessantly growing demand for the eScooter services.

ABSTRACT

In two bus systems, VIRTUAL STATCOM is a widely used device to increase the voltage of weak buses. This work focuses on the modeling and simulation of a two bus system's closed loop controlled virtual STATCOM, which is based on a three-phase voltage source inverter. The study examines and compares closed-loop FOPID and SMC controlled virtual STATCOM systems. All time domain response measures, including steady state error and settling time, are compared. It is noted that the SMC-enabled VIRTUAL STATCOM is faster than the FOPID-controlled system.

The beyond literature does not treaty with closed loop buck boost controlled VIRTUAL-STATCOM. The exceeding credentials do not report the association among FOPID & SMC controlled VIRTUA-STATCOM system. This exertion deals with evaluation of responses through FOPID & SMC controllers.

Mahesh K. Mishra, Senior Member, and B. Kalyan Kumar, Member, IEEE (SEPTEMBER 2013), modeled STATCOM using circuit components in an accurate transmission line model. STATCOM is regarded and recognized as one of the top FACTS devices. It combines series and parallel rapid compensation to offer active and reactive control, resulting in maximum power transfer, system stability, and improved power quality and dependability. As a result, offering an appropriate STATCOM model that allows for the analysis of network and load flow in energy transmission lines has piqued the interest of specialists. This work provides a novel STATCOM steady-state model based on circuit parts from an accurate transmission line model[1].

STATCOM Hierarchical Coordination Controllers Using Non-linear Fuzzy Control Journal of Engineering and Applied Science, ARPN in June 2007 by S. V. R. Kumar and S. S. Nagaraju. This work examines coordination control between two STATCOMs in a multi-machine system. Multiple STATCOMs in a power system can interact, affecting performance and perhaps causing instability. A suggested two-tier hierarchical control method comprises both internal and external controllers. The bus voltage and real/reactive power flow across the transmission line are controlled by internal controls. External controllers send additional reference signals to internal controllers to reduce interaction between two STATCOMs. Takagi-Sugeno fuzzy external controllers outperform traditional PI controllers in terms of decreasing contact. This paper uses a three-machine nine-bus system to show how STATCOMs interact and how the suggested control method works[2].

PROPOSED WORK

Converters based on Buck Boost and a PWM jog method management plan make up the Virtual-STATCOM system. Fig. (1) displays the block schematic of the Virtual-STATCOM with Batteries-powered PWM control, solar power, and wind (1). The control function of the shunt converter is to continuously spritz an odd the transmission line's harmonic current, supplying reactive energy for the shunt converters. To keep its DC voltage constant, the shunt transformer requires a certain amount of reactive power at the fundamental frequency from the grid. The d element of the current at the essential frequency regulates the Voltage

differential of the shunt converter, whereas the q component serves as a compensation about reactive power. An external entity performs the function of power flow control.

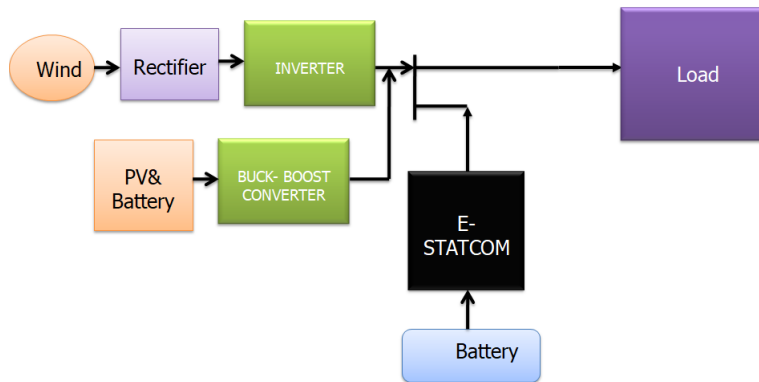

Fig.2.Block Diagram of Virtual -STATCOM

The following describes each of the Control groups' functions that are seen in Fig. (3):

- Power flow control: It determines the essential frequency voltage that the shunt switchers should inject after receiving the system operator's set point for electricity flow.
- Regulation of AC voltage: provides a shunt converter with the set points needed to compensate for reactive power at the fundamental frequency.
- Controlling a shunt converter produces odd harmonized current, reactive power at the fundamental frequency, and DC voltage constancy.

The main goal of the mastery strategy is to compute the Reversing output voltage, u_l , abc, in order to regulate the reference voltage of the capacitor using the dc-link output, V^* , DC in relation to the load, and Voltage and current command reference are incorporated into the smart grid, Q^* . There are several approaches to plan the mastery computational for an AFE. Generally, a corresponding control model is employed. To mastery the voltage of a DC

connection, a peripheral loop in command is activated. Conversely, an interior loop in command is chosen to monitor the smart grid electricity and current citations regarding the mechanism of transfer utilized to amplify this MP manager. The sliding mode controller schematic block shows that the that of the supervisor comprises inaccuracies of twofold or multiple conditions of the arrangement.

CONCLUSION

The schematic for the VIRTUAL STATCOM and Load disruption mechanism is replicated. The circuit diagram for the VIRTUAL STATCOM and closed circuit FOPID controller system is simulated. The circuit diagram for the VIRTUAL STATCOM and closed loop sliding mode controller system is replicated. Time domain characteristics are contrasted to FOPID and SMC controllers. The time of dawn is lowered from 0.41 s to 0.40 s utilizing the SMC controller. Peak duration is lowered from 0.73 s to 0.46 s utilizing the SMC controller. The transitional period is lowered from 0.65 s to 0.52 s by employing the SMC controller. The inaccuracy in the steady-state is decreased the source 1.45 V to 0.34 V by employing an SMC controller. The THD of voltage is decreased from 3.93% to 3.50% utilizing the SMC controller.

Current work focuses on evaluating sliding mode controlled systems and FOPID. In the future, fuzzy logic controlled systems and surpassing schemes responses will be compared side by side. and create a hardware module that is an archetype of single phase.

ABSTRACT

The document presents a nine-level inverter featuring quadruple boosting, tailored for use in small-scale photovoltaic systems. The designed circuit includes capacitors equipped for automatic voltage self-balancing, eliminating the need for extra circuits or intricate control algorithms to ensure voltage equilibrium among the capacitors. setting itself apart from recent topologies, the circuit efficiently generates a nine-level power inverter with quadruple boost amplification at the O/P terminals, utilizing a min no. of components. The paper meticulously elucidates the conducting of circuit analysis and modeling for every o/p level. To maintain balanced capacitor voltage, an optimal switching control approach, employing a straightforward logic control circuit, is implemented, dependent on Pulse Width Modulation (PWM). To assess the efficacy and resilience of this architecture, MATLAB/SIMULINK is employed for validation purposes.

INTRODUCTION

The increasing scarcity of traditional resources has sparked a growing fascination with renewable energy alternatives. Among them, photovoltaic is the most promising due to its non-polluting, noiseless, and cost-effective nature. However, to generate power of superior quality from photovoltaic arrays, appropriate power electronics converters are necessary [1].

PhotoVoltaic systems consists of PhotoVoltaic modules and undergo a dual-stage with the process of power conversion, involving a DC-DC converter and a DC-AC inverter. Conventional two-level inverters are used in DC-AC inverters, but multilevel inverters

(MLIs) are a better option for medium and high voltage/power applications as they produce high-fidelity AC O/P current, eliminating the need for bulk filters.

There are three common topologies for Multi-Level Inverters (MLIs): 1) Cascade H-Bridge (CHB), 2) Flying Capacitor (FC), and 3) Neutral Point Clamped (NPC) [2]. MLIs are widely used in industrial applications to enhance power factor, regulate v/f , mitigate voltage and phase imbalances, and minimize current distortion. As a result, these topologies have been extensively researched and are highly regarded in the industry.

Certainly! The complex control of Cascaded Multilevel Inverter systems can be simplified by incorporating with a amplify switching converter. This involves connecting the DC source and for the H-bridges in each stage, resulting in the creation of boost Cascaded Multilevel Inverters (BCMLIs) [3]. Another approach to streamline the DC-link Multi-Level Inverter system is to enhance it, leading to a reduction in the no.of DC sources and Electrical toggles [4]. Additionally, switched-capacitor multilevel inverters are attractive alternatives due to their lower count of DC supplies.

Different Switched Capacitor unit topologies have been used, producing different o/p v/g level in [5], a 9-level inverter scheme with 2 DC supplies and 2 capacitors has been proposed. It also puts forward two nine-level Switched Capacitor Multi-Level Inverters incorporating two DC supplies and 2 capacitors. Additionally, [6] introduces a integrated switched capacitor-based 9-level inverter. Despite achieving a nine-level voltage output in these topologies, the aspect of boosting is notably absent.

When the direct current (DC) power coming in is lower than the highest voltage required for the load,, certain SCMLI topologies raise the output voltage. Five-level inverters, for instance, can generate a maximum load voltage that is twice the i/p DC voltage in [7] and [8]. Three times the supply voltage is the maximum output voltage that 7-level inverters can produce. The boosting factor of two provided by 9-level inverters in [9] comes at the expense of a large number of components. On the other hand, [10] produced only one-stage, 9-level topologies with quadruple v/g obtain; however, due to their large component count, the circuit is more complicated, expensive, and large.

An economical 9-level switched capacitor quadruple boost multilevel inverter, with a reduced component count is presented in this research. By using switched capacitors as a backup source of DC power, the balancing technique that eliminates the need for additional

voltage balancing control, inductors, and transformers. As a result, fewer components are required, making it more efficient than similar circuit designs can be found in existing literature.

The paper is organized into different parts, and here's how they are divided.

PROPOSED METHOD

SCSML topology comprises a single DC source, eight switches, two diodes, & and two capacitors, by using a DC power supply the circuit capacitors C1 and C2 get charged, resulting in an elevated output voltage. This setup produces nine different voltage levels and increases the voltage across the load by a factor of four.

FIG 1. Proposed design of the switched capacitor- based step up single phase 9 level inverter.

PRINCIPLE OF OPERATING MODES

The inverter that is proposed, shown in Figure 1, has 9 operating modes as described. The Table 1 shows the switch modes of the system. The details of the operation states are explained below.

A. +4Vdc mode: In this level, the load receives power from energy stored in capacitors C1 and C2, as well as the input source. Switches S7, S8, S4, and S1 are turned on.

B. +3Vdc stage: Using the input voltage source and the stored energy in C2, energy is transmitted to the load. This is achieved by switching on S2, S4, S7, and S8. At the same time, C1 is charges upto Vdc, since the capacitor is connected in parallel with the electric supply.

C. In+2Vdc stage: switches S1, S3, S7, and S8 are turned on. The energy was supplied to the load is powered by the stored energy in capacitor C1 and the input voltage source. At the same time, C2 gets charged up to 2Vdc and is connected in parallel to the power supply.

D. +Vdc stage: The load gets its energy from the voltage supply Vdc by turning on S2, S7, and S8. At the same time, C1 is charged with Vdc as it is connected in parallel to the power supply.

E. For the initial level, switch on the S2, S8, and S5 switches. At the same time, allow C1 to charge until its voltage matches that of Vdc since it is connected in parallel with the power supply. The load will not consume any energy in this state.

F. When the -4Vdc level is detected, the switches S1, S4, S5, and S6 are turned on. This mode allows the load to be powered by the energy stored in capacitors C1 and C2, rather than the input source.

G. When the voltage level drops to -3Vdc, The energy needed to operate the load comes the system gets power from the stored energy in capacitor C2 and the input voltage source. This happens when switches S2, S4, S5, and S6 are turned on. At the same time, C1 is charged up to Vdc, as the capacitor is connected in parallel with the power supply.

TABLE 1. The conditions of the capacitors and the positions of the switches in the circuit.

	Capacitor modes			Switches modes		
	C1	C2	S8	S7	S6	S5
V0/Vin						
-4	D	D	0	0	1	1
-3	C	D	0	0	1	1
-2	D	C	0	0	1	1
-1	C	No	0	0	1	1

0	C	No	0	1	1	0
+1	C	No	1	1	0	0
+2	D	C	1	1	0	0
+3	C	D	1	1	0	0
+4	D	D	1	1	0	0

H. When the -2Vdc level is reached, switches S5, S3, S1, and S6 are turned on. The load is powered by the energy that is stored in C1 and the i/p voltage source. At the same time, C2 is charged up to 2Vdc and runs in parallel with the power supply.

TABLE 2. Voltage stress for switches' circuit.

S1	S2	S3	S4	S5	S6	S7	S8
Vin	Vin	2Vin	2Vin	4Vin	4Vin	4Vin	4Vin

I. When the load draws energy from the voltage source Vdc at the -1Vdc level, it necessitates the activation of S2, S5, and S6. Simultaneously, C1 undergoes charging with Vdc, as it is in parallel to the power source. Referring to Table 1, the switching pattern is outlined, where (1) indicates the ON state and (0) signifies the OFF state. The status of capacitor Cis categorized as charging (C), discharging (D), or not connected (No).

J. TSV is crucial for MLI design; it shows the highest voltage that switches may block. Table 2 outlines voltage stress for device components .The supply voltage is equal to the voltage stress of S1 and S2 . S3 & S4 have double the value of supply power. The leftover switches have a voltage stress equal to four times the input voltage. Calculate TSV using this formula:

$$TSV = \frac{\sum_{i=1}^n V_{b\text{switch}.i} + \sum_{j=1}^n V_{b\text{diode}.j}}{V_{0\text{max}}} \quad (1)$$

Vbswitch and Vbdiode represent the maximum voltage capacity for the switch and diode, respectively, ensuring effective current blockage within the circuit. The parameter Vomax indicates the peak output voltage level achievable within this specific arrangement. Both the switch and diode are characterized by a threshold voltage denoted by the symbol 'j', which

serves as the maximum voltage threshold, effectively preventing any undesired current flow, as outlined in references [11] and [20].

MODULATION TECHNIQUE AND SWITCHING TABLE

Power converter modulation strategies commonly employ the pulse-width modulation approach. This setup uses a method called multi-carrier PWM. The number of carriers (which are like signals) used is related to the number of different output voltage levels. So, if you have N levels of output voltage, you use N-1 carriers. In this case, they're using 8 carriers, each with the same strength and frequency, but with different starting voltages. They compare these carriers to a sine wave reference using logic gates to generate the switching signals needed for the system. "The result of this comparison is that there are 8 pulses which need to be applied to 8 different switches." The Figure 2 follows the table1.

FIGURE 2. MODULATION SCHEME

FIGURE 3. LOGIC OPERATORS FOR GATE SIGNALS

FIG 4: GENERATION OF GATE PULSES FOR ALL SWITCHES

In this schema, X1 is obtained from the combination of (Vcr1, Vref), X2 from (Vref, Vcr2), and so on. Furthermore, Figure 2 investigates the waveform of the gate signals resulting from the comparison and the switching logic.

$$MI = \frac{V_{ref}}{4V_{cr}} \quad (2)$$

To demonstrate the benefits of the suggested 9-level topology, various characteristics were compared, including the no. of components, the max no. of ON toggles in a single mode, the max voltage rating of capacitors, the overall voltage stress, and the topologies' obtain. Fewer switches are needed for the Aimerd system to create nine levels than for the topologies suggested in [9], [10], [18], and [19]. less than the topologies suggested in [8] although they offer fewer output-boosting levels. Lower switch counts consequently resulted in lower conduction losses. Different topologies' voltage gain and overall voltage stress were compared. Reduced TSV values will result in lower inverter costs, and vice versa. It is possible to estimate a factor known as the cost function using equation (3):

$$CF = \left(N_s + N_{driver} + N_d + \frac{\alpha(TSV)_{pu}}{Gain} \right) \quad (3)$$

The weight coefficient factor (α) determines this factor. It may be nearly equal to one [13], [14]. Therefore, this paper's primary objective is to decrease the component count while preserving low TSV and a cheaper suggested inverter cost in comparison to alternative topologies.

LOSS CALCULATIONS

Semiconductor devices have two main types of losses: switching losses and conduction losses. Switching losses happen because of delays when turning the device on or off. Conduction losses occur when the device is actively conducting electricity. Capacitor losses in Semiconductor Capacitor-Modeling Level Interface (SCMLI) are due to factors like electric series resistance (ESR) and reactance. To calculate these losses, we use Equations (4) for switches and Equations (5) for diodes.

$$P_{con_s} = V_{s_on} * i_{s_avg} + R_{s_on} * i_{s_rms}^2 \quad (4)$$

$$P_{con_d} = V_{d_on} * i_{d_avg} + R_{d_on} * i_{d_rms}^2 \quad (5)$$

where Pcon_D represents the conduction losses of the diode and Pcon_s represents the conduction losses of the switch. The voltage across the switch when it is in the on state is represented by Vs_on. The voltage across the diode in the on-state is denoted by Vd_on. For the switch, the on-state resistance is Rs_on, and for the diode, it is Rd_on. We're examining the typical and effective currents in switches and diodes are denoted by the variables is_avg, is_rms, id_avg, and id_rms, respectively.

$$\begin{aligned}
 P_{con(V_0=+1V_{dc})} &= 3(V_{s_on} * i_{s_avg} + R_{s_on} * i_{s_rms}^2) \\
 &\quad + 2(V_{d_on} * i_{d_avg} + R_{d_on} * i_{d_rms}^2) \\

 P_{con(V_0=-1V_{dc})} &= 3(V_{s_on} * i_{s_avg} + R_{s_on} * i_{s_rms}^2) \\
 &\quad + 2(V_{d_on} * i_{d_avg} + R_{d_on} * i_{d_rms}^2) \\
 P_{con(V_0=-2V_{dc})} &= 4(V_{s_on} * i_{s_avg} + R_{s_on} * i_{s_rms}^2) \\
 &\quad + (V_{d_on} * i_{d_avg} + R_{d_on} * i_{d_rms}^2)
 \end{aligned}$$

$$\begin{aligned}
 P_{con(V_0 = -3V_{dc})} &= 4 \left(V_{s_on} * i_{s_avg} + R_{s_on} * i_{s_rms}^2 \right) \\
 &\quad + \left(V_{d_on} * i_{d_avg} + R_{d_on} * i_{d_rms}^2 \right) \\
 P_{con(V_0 = -4V_{dc})} &= 4 \left(V_{s_on} * i_{s_avg} + R_{s_on} * i_{s_rms}^2 \right)
 \end{aligned}
 \tag{6}$$

The o/p voltage, the number of diodes and the switches vary in each stage during conduction. As a result, using equation (6), the losses are determined independently for every level. Three switches and a single diode are turned on at +1Vdc and -1Vdc levels. Only the three switches are in the conduction during the +2Vdc and -2Vdc levels. However, only four switches are in the conduction at +4Vdc and -4Vdc levels. Equation (7) indicates that the total estimated losses during circulation are calculated by summing up the deficits from every individual stage.

$$\begin{aligned}
 P_{con(total)} &= P_{con(V_0 = +1V_{dc})} + P_{con(V_0 = +2V_{dc})} \\
 &\quad + P_{con(V_0 = +3V_{dc})} + P_{con(V_0 = +4V_{dc})} \\
 &\quad + P_{con(V_0 = -1V_{dc})} + P_{con(V_0 = -2V_{dc})} \\
 &\quad + P_{con(V_0 = -3V_{dc})} + P_{con(V_0 = -4V_{dc})}
 \end{aligned}
 \tag{7}$$

SWITCHING LOSSES

Switching losses occur due to non-instantaneous activate and deactivate processes. When the switch is activated, the current at the collector terminal gradually grows as the voltage between the gate and emitter surpasses a threshold. Simultaneously, the voltage across the transistor terminals diminishes to Vsw-on, and Isw-on is achieved in less than a second.. Equation (8) shows that during tonne, collector current and collector emitter voltage have limited nonzero values, leading to on-time switching losses. When turning off, the values of IC and VCE are restricted during the off time, resulting in the turn-off switching losses as indicated in Equation (9).

The terms PSL, I (ON) denote the switching loss during the activation of the ith switch, while PSL, I (OFF) signifies the switching loss during the deactivation of the ith switch.

$$\begin{aligned}
 P_{SL,i(on)} &= f_{cr} \int_0^{t_{on}} V_{s_off,i}(t) * i(t) dt \\
 &= f_{cr} \int_0^{t_{on}} \left(-\frac{V_{s_off,i}}{t_{on}} (t - t_{on}) \right) \left(\frac{I_{s_on,i}}{t_{on}} t \right) dt \quad = \frac{1}{6} f_{cr} * V_{s_off,i} * I_{s_on,i} * t_{on} \quad (8)
 \end{aligned}$$

$$\begin{aligned}
 P_{SL,i(off)} &= f_{cr} \int_0^{t_{off}} V_{s_off,i}(t) * i(t) dt \\
 &= f_{cr} \int_0^{t_{off}} \left(\frac{V_{s_off,i}}{t_{off}} t \right) \left(-\frac{I_{s_off,i}}{t_{off}} (t - t_{off}) \right) dt \quad = \frac{1}{6} f_{cr} * V_{s_off,i} * I_{s_off,i} * t_{off} \quad (9)
 \end{aligned}$$

Adding up the losses when the switches turn on and off using Equation (10) allows you to find the total switching losses.

$$P_{SL(total)} = \sum_{i=1}^{N_s} \left(\sum_{j=1}^{N_{on(i)}} P_{SL,on(ij)} + \sum_{j=1}^{N_{off(i)}} P_{SL,off(ij)} \right) \quad (10)$$

where N_{sw} represents the total no. of toggles, $PSL_{(total)}$ represents the total switching losses, and N_{s_on} and N_{s_off} are the no. of turn-on and turn-off in a single cycle, in order, in the Multi level inverter topology.

CAPACITOR LOSSES

The losses presents in the capacitor happen because of the voltage decrease Over the reactance of capacitance & electrical series resistance. When in the mode of charging , the capacitor and the power source are connected side by side. Ripple loss occurs due to the voltage variation ($1V_c$) among the intended and actual voltages for a capacitor. You can use the following formula to figure out the factor that determines the ripple voltage for each capacitor.

$$\Delta V_c = \frac{1}{C} \int_0^{t_c} I_c(t) dt \quad (11)$$

Where as charging current (I_c) and charging time (t_c) are expressed. One can calculate the energy loss from:

$$E_{ripp} = \frac{1}{2} C \Delta V_c^2 \quad (12)$$

Ripple power loss is derived as:

$$P_{ripple} = \frac{f_0}{2} C \Delta V_c^2 \quad (13)$$

Where is the fundamental frequency located?

During the discharging phase, the capacitors' conduction losses are induced by the ESR. The source and capacitor are linked in series. The following is an estimate of these losses:

$$P_{esr} = i_c^2 * R_{c_esr} \quad (14)$$

The MLI efficiency is showed in Equations (15) and (16):

$$efficiency \eta = \left(\frac{P_{input} - P_{losses}}{P_{input}} \right) * 100 \quad (15)$$

$$\eta = \left(\frac{V_{dc} * I_{dc} - P_{con(total)} - P_{SL(total)} - P_{rl}}{V_{dc} * I_{dc}} \right) * 100 \quad (16)$$

Where Pcon represents the combined conduction losses and PSL represents the total switching losses across all switches respectively, and efficiency is the multi-level inverters efficiency. The i/p direct current voltage and current are represented by Vdc and Idc, respectively.

SIMULATION RESULTS

The MATLAB-Simulink software is used to evaluate the nine-level SCQBMLI, which is depicted in Figure 1. The system is examined under several circumstances. The values needed to verify the suggested topology at an i/p supply of 100 V are listed in Table 4. the voltages of the capacitors and the resulting output voltage for

show the switching frequency (F_{sw}) at 100 and 5000 Hz, respectively. It's clear that C1's While C2's voltage changes around 200 V, which is equivalent to double the supply voltage, the voltage fluctuates around 100 V, which is the value of the supply voltage. Without the aid of a stability control scheme, the capacitor voltages self-balance. It is also clear that there are nine voltage levels in the generated output voltage, with a maximum peak value of 4 Vdc. An increase in carrier frequency is observed to result in more switching at each level, which raises switching losses. while grid-connecting applications, however, the size of the filter is reduced since, while raising the carrier frequency, the harmonics are altered to a higher order.

The O/P v/g and current of the inverter are shown for a load shift in Fig. 6. First, the load was connected to R-L load = 400, and then the load case was changed to no load. Lastly, A device for a direct current (DC) power supply with a voltage of 100 volts and a switching frequency (F_{sw}) of 5000 Hertz, is linked to an R-L load of $400\Omega + 150\text{ mH}$.

Fig. 9 shows the varying modulation index (MI) under inductive load in another example study. Current and output voltage are examined for various MI values, including MI = 0.8, 0.9, and 1. The voltage levels of the inverter are maintained under these conditions, but the $\pm 4\text{Vdc}$ width varies. This is similar to basic component fluctuations of 317.1V, 361.2V, and 390.5V for Modulation Index = 0.8, 0.9, and 1, in order. Electric load current, Load v/g are noted in Fig. 10 for the additional conditions of MI= 0.4, 0.7, and 1. For MI = 0.4, 0.7, and 1, respectively, the inverter v/g levels are adjusted to 5, 7, and 9, and as a result, the load current value is altered. Comparing a modulated signal with just four carriers from Cr3–Cr6 led to this outcome. We are comparing six carriers from Cr2–Cr7 and eight carriers from Cr1–Cr8 when modulation index is set at 0.7 and 1.

Fig. 10 shows the relationship between the output current and the capacitor's voltage ripple for various resistive loads. It is seen that the voltage ripples for Capacitor 1 and Capacitor 2 are 10 and 9.3 volts, respectively, for a resistive load equal to 50. These voltage ripple values are below permitted levels.

Figures 11(a) and 11(b) show the results of the FFT evaluation for the O/P voltage and O/P current, respectively, taking into account the inductive load. The THD for voltage and current is 2.72% for current and 13.05% for voltage.

CONCLUSION

In conclusion, the presented nine-level inverter with quadruple boosting represents a significant advancement in small-scale photovoltaic systems. The circuit's innovative design incorporates capacitors with automatic voltage self-balancing, eliminating the need for additional circuits or complex control algorithms to ensure voltage equilibrium. This unique feature sets it apart from recent topologies, offering efficient nine-level power inversion with quadruple boost amplification while utilizing a minimal number of components.

The paper thoroughly explores circuit analysis and modeling for each output level, providing a comprehensive understanding of its operation. To maintain balanced capacitor voltage, an optimal switching control approach, facilitated by a straightforward logic control circuit dependent on Pulse Width Modulation (PWM), is implemented.

Validation through MATLAB/SIMULINK demonstrates the efficacy and resilience of the proposed architecture. Overall, this project not only introduces a novel inverter design but also showcases a practical and efficient approach to voltage balancing and control in photovoltaic systems.

ABSTRACT

The interest on Electric Vehicles (EV) have increased now a days on behalf of the global threat of fossil fuel depletion and increasing environmental effects due to the usage of those fuels. The EV battery has to cope up with time to time power variations and the charging profile is also different with that of other batteries. Hence a battery charger which can provide wide output voltage according to the demand is needed for EVs and such a charger is proposed in this project. The design and development of a resonant LLC dc-dc converter is explained where this type of converters can work in higher frequencies thus reducing the size of the involved components and can execute soft switching techniques so as to increase the efficiency of the system.

CHAPTER 1

INTRODUCTION

The Continued technological innovations in battery and electric drivetrain have made electric vehicles (EVs) a viable solution for a sustainable transportation system. Currently, most EV charging is done either at residences, or for free at some public charging infrastructure provided by municipalities, office buildings, etc. As the EV industry continues to grow, commercial charging stations will need to be strategically added and placed. Development of effective management and regulation of EV charging infrastructure needs to consider the benefits of multiple constituencies consumers, charging station owners,

power grid operators, local government, etc. In this paper, we concentrate on striking a balance among the profits of charging station owners, consumer satisfaction, and power grid's reliability. Our work is motivated by the desire of service providers to make a forward-looking decision on charging station placement to obtain a good return on their investment. We use the most up-to-date information (i.e., travel pattern, traffic flow, road network, power grid, etc.) to make the best-effort decisions on charging station placement, hoping that service providers will have a good chance to profit over the next few years.

In this paper, we do not consider factors such as uncertainties in fuel prices, climate change, population migration etc., which are random and unpredictable. Instead, we assume that some revenue management techniques (i.e., real-time pricing) may be applied to deal with the potential effects of these factors. We assume that the service providers aim to strike a balance between the competing goals of maximizing their profits and minimizing the disturbance to the electric power network due to large-scale EV charging. Accordingly, we construct a utility function that incorporates both of the aims. Each charging service provider attempts to maximize his/her own expected utility function while satisfying the Quality-of-Service (QoS) constraints through choosing the optimal locations of charging stations that s/he owns. The nested logit model is used to analyze and predict the charging preference of EV owners. At the beginning of each stage, the service providers predict the charging demand of each charging station candidate using the nested logit model. The optimal placement strategy is obtained through a Bayesian game.

As the EV penetration rate increases, the existing charging stations may no longer satisfy the QoS constraints and a new stage shall be initiated to place more charging stations.

REPORT OVERVIEW

This project report has been organized into six chapters. The first chapter described the introduction, problem statement, and objectives of the work. The remaining chapters are given below.

Chapter 2 covers the literature survey.

Chapter 3 explains the block diagram, circuit diagram, and procedure of the work

Chapter 4 covers the hardware and description used for this work.

Chapter 5 describes the conclusions and further scope.

CHAPTER 2

LITERATURE SURVEY

INTRODUCTION

Wireless Power Transmission (WPT) is the efficient transmission of electric power from one point to another point through a vacuum or an atmosphere without the use of wire or any other substance. This can be used for applications where either an instantaneous amount or a continuous delivery of energy is needed, but where conventional wires are unaffordable, inconvenient, expensive, hazardous, unwanted or impossible. The power can be transmitted using Inductive coupling for shortrange, Resonant Induction for mid-range and Electromagnetic wave power transfer for high range. WPT is a technology that can transport power to locations, which are otherwise not possible or impractical to reach. Charging the battery of electric vehicles by means of inductive coupling could be the next big thing.

CONVENTIONAL BATTERY CHARGER FOR EV

PAPER 1

Reactive Power Compensation using Vehicle-to-Grid enabled Bidirectional Off-Board EV Battery Charger

Abstract:

The application of a grid-connected off-board Electric vehicle (EV) battery charger on the reactive power compensation and simultaneously use as a battery charger (grid-to-vehicle (G2V)) and power generator (vehicle-to-grid (V2G)). The topology of the charger consists of a grid facing front-end AC-DC cascaded H-bridge bidirectional converter, which controls the power flow between the grid and EV battery using a back-end DC-DC bidirectional converter. The charger configuration provides galvanic isolation at the user end from the rest of the system as a safety measure. The proposed control algorithm follows the active power command for G2V and V2G operation along with reactive power command from the utility grid when requested, by controlling EV current and battery current. Furthermore, an adaptive notch filter based controller is designed for system phase estimation and generated reference current synchronization.

PAPER 2

A Sensorless control strategy of a Single-stage fast EV battery charger based on the Voltage-type PWM Converter

Abstract:

Voltage type PWM converter has been widely used in high-power bidirectional chargers due to its advantages such as flexible control, adjustable power factor, and bidirectional energy flow. However, traditional electric vehicle charger generally adopts the two-stage structure, and its rated operating point efficiency is lower than 95%, and further improvement of efficiency will significantly increase the costs. On the other hand, in order to further improve the power of electric vehicle, its voltage level is gradually developing towards a high voltage of 800V. Therefore, this paper proposes a single-stage fast electric vehicle (EV) charger based on the voltage-type PWM converter for 800V voltage level and its corresponding control strategy without DC current sensor. Finally, a set of fast EV battery charger experiment platform based on voltage-type PWM converter is built to verify the

correctness of the sensorless control strategy proposed in this paper and the practicability of the single-stage fast EV battery charger structure based on the voltage-type PWM converter.

PAPER 3

An Integrated Battery Charger for EV applications based on an Open End Winding Multilevel Converter configuration

ABSTRACT:

A new approach to realize an integrated battery charger is described in this paper, based on the Asymmetrical Hybrid Multilevel Converter topology. Such a particular open-end winding motor configuration has proved to be more efficient than conventional inverter .

topologies in EV motor drive applications but it can be also turned in an on-board battery charger only by acting on the control system. Thus, no additional components, nor circuit reconfiguration through extra power switches are required. Moreover, the obtained battery charger can be supplied either by a standard AC single-phase grid, either by a DC power source for fast recharging.

PAPER 4

Design and Development of a Resonant Converter Adapted to Wide Output Range in EV Battery Chargers

Abstract:

The interest on Electric Vehicles (EV) have increased nowadays on behalf of the global threat of fossil fuel depletion and increasing environmental effects due to the usage of those fuels. The EV battery has to cope up with time to time power variations and the charging profile is also different with that of other batteries. Hence a battery charger which can provide wide output voltage according to the demand is needed for EVs and such a charger is proposed in this paper. The design and development of a resonant LLC dc-dc converter is explained where this type of converters can work in higher frequencies thus reducing the size of the involved components and can execute soft switching techniques so as to increase the efficiency of the system. A 30kW battery charger is designed and the effectiveness of the system is verified by MATLAB/SIMULINK.

PAPER 5**A novel single-phase five-level active rectifier for on-board EV battery chargers**

Abstract:

This paper presents a novel single-phase active rectifier for applications of on-board EV battery chargers. The proposed active rectifier, with reduced number of semiconductors, is constituted by four MOSFETs and four diodes, and can produce five distinct voltage levels, allowing to reduce the passive filters used to interface with the electrical power grid. An almost sinusoidal grid current with unitary power factor is achieved in the grid side for all the operating power range, contributing to preserve the power quality. The principle of operation, the current control strategy and the modulation technique are presented in detail. Simulation results in different conditions of operation are presented to highlight the feasibility and advantages of the proposed active rectifier.

PAPER 6**Optimizing parallel connection of Medium Frequency inverters for EV Wireless Charging**

Abstract:

Wireless battery charging has recognized advantages over conductive charging and is the preferred solution for driverless electric vehicles of the near future. At present, the powers transferred through the two systems are standardized in the power series 3.7 - 7.4 - 11 - 22 kW. From the justified desire that the duration of the loading process be comparable to the duration of the petrol supply of conventional vehicles with internal combustion engines, fast charging systems have been developed that can transmit power that reaches hundreds of kW. The paper analyzes the possibility of economically realizing a high power wireless charging by mounting in parallel “n” identical inverters modules, controlled by a robust and adaptive control loop. The conditions for achieving a smart adaptive micro-grid are met. A new topology for power circuits and a control structure for micro-grid-connected inverters with non-shock-free operation and balanced distribution of power and current between inverters is proposed.

PAPER 7

Wireless Opportunity Charging as an Enabling Technology for EV Battery Size Reduction and Range Extension

Abstract:

Opportunity charging of electric vehicles (EVs) during brief stops is an important application of wireless power transfer (WPT). Irrespective of the specific WPT technology used, it is possible to quantify the effect of opportunity charging on EVs using energy calculations. This paper presents an analysis of the potential reduction in battery size and extension in EV range enabled by opportunity charging, using urban driving cycle data and various charging power levels. Traction power expended for acceleration, and to overcome air drag and rolling friction are considered. Depending on the extent of opportunity charging, battery size reduction from 6% to 85% is possible. Alternatively, retaining the battery size at its base value, a range extension between 7% and 600% is realizable. Although the results are shown for a particular velocity profile, the generalized analysis method presented in this paper can cater to various types of driving cycles.

PAPER 8

A Miniaturized Single-Ended Wireless EV Charger with New High Power-Factor Drive and Natural Cooling Structure

Abstract:

This paper deals with a miniaturized wireless EV charger with a new high power-factor drive and natural cooling structure that incorporates the simple quasi-resonant single-ended inverter. In the first place, the operating principle of a wireless EV charger using the one switch inverter is described. This type of wireless resonant EV charger can efficiently operate under zero volt switching (ZVS). In the second place, a low-cost small-size high power-factor drive method is proposed. In a new high power-factor drive wireless EV charger with a non-smoothing pulsating voltage fed inverter, ripple components are absorbed in EV battery at the final stage of the system, while they are usually absorbed in a large smoothing capacitor before the inverter. Illustrated is that AC input current is expected to have high power-factor and low total harmonic distortion (THD). Finally, described is a design of high-density power implementation with a new natural cooling construction for achieving high reliability. All generated heat in the unit is dissipated through a unit case. Thanks to this

study, the volume and weight of converter are extremely decreased, and solve the problem of power factor and cooling.

PAPER 9

Wireless power transfer for running EV powering using multi-parallel segmented rails

Abstract:

The conventional static wireless powering technology for electric vehicles (EV) has the disadvantages of non-running powering and frequent charging times. To solve the above problems, a novel wireless power transfer (WPT) technology for dynamic roadway EV powering using multiple parallel segmented rails is proposed in this paper. Firstly, currently several dynamic powering methods are compared. Then, circuit model and transfer function is established to analyze the topology of this proposed LCL resonator, respectively. Finally, transient response time of the topology is calculated by using the dominant pole method. Both simulation and experimental results demonstrate that the proposed strategy can achieve oven power flow and significant efficiency improvement compared with the traditional structure.

SYSTEM ANALYSIS

EXISTING SYSTEM

Now a day's world is shifting towards electrified mobility to reduce the pollutant emissions caused by non-renewable fossil fueled vehicles and to provide the alternative to pricey fuel for transportation. But for electric vehicles, traveling range and charging process are the two major issues affecting it's adoption over conventional vehicles. With the introduction of Wire charging technology, no more waiting at charging stations for hours, now get your vehicle charged by just parking it on parking spot or by parking at your garage or even while driving you can charge your electric vehicle. As of now, we are very much familiar with wireless transmission of data, audio and video signals so why can't we transfer power over the Air. Thanks to great scientist Nikola Tesla for his limitless amazing inventions in which wireless power transfer is one of them. He started his experiment on wireless power transmission in 1891 and developed Tesla coil. In 1901 with the primary goal

to develop a new wireless power transmission system Tesla started developing the Wardencllyffe Tower for large high-voltage wireless energy transmission station.

ARDUINO SOFTWARE (IDE)

Arduino is an open-source hardware and software company, project, and user community that designs and manufactures single-board microcontrollers and microcontroller kits for building digital devices. Its hardware products are licensed under a CC BY-SA license, while the software is licensed under the GNU Lesser General Public License (LGPL) or the GNU General Public License (GPL), permitting the manufacture of Arduino boards and software distribution by anyone. Arduino boards are available commercially from the official website or through authorized distributors.

The Arduino project began in 2005 as a tool for students at the Interaction Design Institute Ivrea, Italy, aiming to provide a low-cost and easy way for novices and professionals to create devices that interact with their environment using sensors and actuators. Common examples of such devices intended for beginner hobbyists include simple robots, thermostats, and motion detectors. The name Arduino comes from a bar in Ivrea, Italy,

where some of the project's founders used to meet. The bar was named after Arduin of Ivrea, who was the margrave of the March of Ivrea and King of Italy from 1002 to 1014.

Arduino is an open-source electronics platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing.

Arduino has been the brain of thousands of projects, from everyday objects to complex scientific instruments. A worldwide community of makers - students, hobbyists, artists, programmers, and professionals - has gathered around this open-source platform, their contributions have added up to an incredible amount of accessible knowledge that can be of great help to novices and experts alike.

Arduino was born at the Ivrea Interaction Design Institute as an easy tool for fast prototyping, aimed at students without a background in electronics and programming. As soon as it reached a wider community, the Arduino board started changing to adapt to new needs and challenges, differentiating its offer from simple 8-bit boards to products for IoT applications, wearable, 3D printing, and embedded environments. All Arduino boards are completely open-source, empowering users to build them independently and eventually adapt them to their particular needs. The software, too, is open-source, and it is growing through the contributions of users worldwide.

Arduino also simplifies the process of working with microcontrollers, but it offers some advantage for teachers, students, and interested amateurs over other systems:

Inexpensive - Arduino boards are relatively inexpensive compared to other microcontroller platforms. The least expensive version of the Arduino module can be assembled by hand, and even the pre-assembled Arduino modules cost less than \$50.

Cross-platform - The Arduino Software (IDE) runs on Windows, Macintosh OSX, and Linux operating systems. Most microcontroller systems are limited to Windows.

Simple, clear programming environment - The Arduino Software (IDE) is easy-to use for beginners, yet flexible enough for advanced users to take advantage of as well. For

teachers, it's conveniently based on the Processing programming environment, so students learning to program in that environment will be familiar with how the Arduino IDE works.

Open source and extensible software - The Arduino software is published as open source tools, available for extension by experienced programmers. The language can be expanded through C++ libraries, and people wanting to understand the technical details can make the leap from Arduino to the AVR C programming language on which it's based. Similarly, you can add AVR-C code directly into your Arduino programs if you want to.

Open source and extensible hardware - The plans of the Arduino boards are published under a Creative Commons license, so experienced circuit designers can make their own version of the module, extending it and improving it. Even relatively inexperienced users can build the breadboard version of the module in order to understand how it works and save money.

FIGURE 4: Software Installing

The process will extract and install all the required files to execute properly the Arduino Software (IDE).

Embedded C

Embedded C is a set of language extensions for the C programming language by the C Standards Committee to address commonality issues that exist between C extensions for different embedded systems. Embedded C programming typically requires nonstandard extensions to the C language in order to support enhanced microprocessor features such as fixed- point arithmetic, multiple distinct memory banks, and basic I/O operations. In 2008, the C Standards Committee extended the C language to address such capabilities by providing a common standard for all implementations to adhere to. It includes a number of

features not available in normal C, such as fixed-point arithmetic, named address spaces and basic I/O hardware addressing. Embedded C uses most of the syntax and semantics of standard C, e.g., `main()` function, variable definition, datatype declaration, conditional statements (if, switch case), loops (while, for), functions, arrays and strings, structures and union, bit operations, macros, etc.

Embedded C Programming is the soul of the processor functioning inside each and every embedded system we come across in our daily life, such as mobile phone, washing machine, and digital camera. Each processor is associated with an embedded software. The first and foremost thing is the embedded software that decides functioning of the embedded system. Embedded C language is most frequently used to program the microcontroller.

FIGURE 5: ARCHITECTURE

Earlier, many embedded applications were developed using assembly level programming. However, they did not provide portability. This disadvantage was overcome by the advent of various high level languages like C, Pascal, and COBOL. However, it was the C language that got extensive acceptance for embedded systems, and it continues to do so. The C code written is more reliable, scalable, and portable; and in fact, much easier to understand. C language was developed by Dennis Ritchie in 1969. C language is a middle-level language as it supports high-level applications and low-level applications. Before going into the details of embedded C programming, we should know about RAM memory organization. Function is a collection of statements that is used for performing a specific task and a collection of one or more functions is called a programming language. Every language is consisting of basic elements and grammatical rules. The C language programming is

designed for function with variables, character set, data types, keywords, expression and so on are used for writing a C .

PROTEUS

The Proteus Design Suite is a proprietary software tool suite used primarily for electronic design automation. The software is used mainly by electronic design engineers and technicians to create schematics and electronic prints for manufacturing printed circuit boards. It was developed in Yorkshire, England by Labcenter Electronics Ltd and is available in English, French, Spanish and Chinese languages. The Proteus Design Suite is a Windows application for schematic capture, simulation, and PCB (Printed Circuit Board) layout design. It can be purchased in many configurations, depending on the size of designs being produced and the requirements for microcontroller simulation. All PCB Design products include an auto router and basic mixed mode SPICE simulation capabilities.

The micro-controller simulation in Proteus works by applying either a hex file or a debug file to the microcontroller part on the schematic. It is then co-simulated along with any analog and digital electronics connected to it. This enables its use in a broad spectrum of project prototyping in areas such as motor control, temperature control and user interface design. It also finds use in the general hobbyist community and, since no hardware is required, is convenient to use as a training or teaching tool. Support is available for co-simulation of

POWER SUPPLY UNIT

The present chapter introduces the operation of power supply circuits built using filters, rectifiers, and then voltage regulators Starting with an AC voltage a steady DC voltage is obtained by rectifying the AC voltage then filtering to a DC level, and finally, regulating to

obtain a desired fixed DC voltage. The regulation is usually obtained from an IC voltage regulator unit, which takes a DC voltage and provides a somewhat lower DC voltage, which remains the same even if the input DC voltage varies, or the output load connected to the DC voltage changes.

A power supply is an electrical device that supplies electric power to an electrical load. The main purpose of a power supply is to convert electric current from a source to the correct voltage, current, and frequency to power the load. As a result, power supplies are sometimes referred to as electric power converters. Some power supplies are separate standalone pieces of equipment, while others are built into the load appliances that they power. Examples of the latter include power supplies found in desktop computers and consumer electronics devices. Other functions that power supplies may perform include limiting the current drawn by the load to safe levels, shutting off the current in the event of an electrical fault, power conditioning to prevent electronic noise or voltage surges on the input from reaching the load, power-factor correction, and storing energy so it can continue to power the load in the event of a temporary interruption in the source power (uninterruptible power supply).

All power supplies have a power input connection, which receives energy in the form of electric current from a source, and one or more power output or rail connections that deliver current to the load. The source power may come from the electric power grid, such as an electrical outlet, energy storage devices such as batteries or fuel cells, generators or alternators, solar power converters, or another power supply. The input and output are usually hardwired circuit connections, though some power supplies employ wireless energy transfer to power their loads without wired connections. Some power supplies have other types of inputs and outputs as well, for functions such as external monitoring and control.

Power supplies are categorized in various ways, including by functional features. For example, a regulated power supply is one that maintains constant output voltage or current despite variations in load current or input voltage. Conversely, the output of an unregulated power supply can change significantly when its input voltage or load current changes. Adjustable power supplies allow the output voltage or current to be programmed by mechanical controls (e.g., knobs on the power supply front panel), or by means of a control input, or both. An adjustable regulated power supply is one that is both adjustable and regulated. An isolated power supply has a power output that is electrically independent of

its power input; this is in contrast to other power supplies that share a common connection between power input and output.

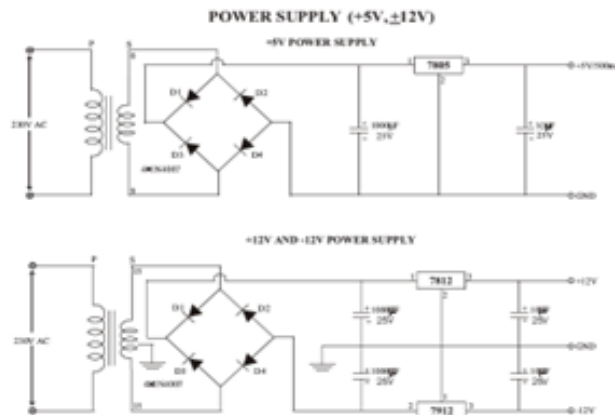

FIGURE 6: Diagrams for Power Supply

IC VOLTAGE REGULATORS

Voltage regulators comprise a class of widely used ICs. Regulator IC units contain the circuitry for reference source, comparator amplifier, control device, and overload protection all in a single IC. Although the internal construction of the IC is somewhat different from that described for discrete voltage regulator circuits, the external operation is much the same. IC units provide regulation of either a fixed positive voltage, a fixed negative voltage, or an adjustable set voltage. A power supply can be built using a transformer connected to the AC supply line to step the AC voltage to desired amplitude, then rectifying that AC voltage, filtering with a capacitor and RC filter, if desired, and finally regulating the DC voltage using an IC regulator. The regulators can be selected for operation with load currents from hundreds of Millis amperes to tens of amperes, corresponding to power ratings from mill watts to tens of watts. C Switching Voltage Regulators IC switching voltage regulators are integrated circuits (ICs) that store energy in an inductor, transformer, or capacitor and then use this storage device to transfer energy from the input to the output in discrete packets over a low-resistance switch.

The function of a voltage regulator is to maintain a constant DC voltage at the output irrespective of voltage fluctuations at the input and (or) variations in the load current. In other words, voltage regulator produces a regulated DC output voltage. Voltage regulators are also available in Integrated Circuits (IC) forms. These are called as voltage regulator ICs.

A fixed voltage regulator produces a fixed DC output voltage, which is either positive or negative. In other words, some fixed voltage regulators produce positive fixed DC voltage values, while others produce negative fixed DC voltage values. 78xx voltage regulator ICs produce positive fixed DC voltage values, whereas, 79xx voltage regulator ICs produce negative fixed DC voltage values.

An adjustable voltage regulator produces a DC output voltage, which can be adjusted to any other value of certain voltage range. Hence, adjustable voltage regulator is also called as a variable voltage regulator. The DC output voltage value of an adjustable voltage regulator can be either positive or negative.

LM317 voltage regulator IC

LM317 voltage regulator IC can be used for producing a desired positive fixed DC voltage value of the available voltage range.

LM317 voltage regulator IC has 3 pins. The first pin is used for adjusting the output voltage, second pin is used for collecting the output and third pin is used for connecting the input.

THREE-TERMINAL VOLTAGE REGULATORS

Fig shows the basic connection of a three-terminal voltage regulator IC to a load. The fixed voltage regulator has an unregulated DC input voltage, V_I , applied to one input terminal, a regulated output DC voltage, V_o , from a second terminal, with the third terminal connected to ground. The specifications also list the amount of output voltage change resulting from a change in load current (load regulation) or in input voltage (line regulation).

The capacitors are used for decoupling and don't affect the dc operations. There is one input, one output and one adjustable terminal. The output voltage can be varied from 1.2V to 37V depending upon the resistor values. The LM 317 can provide up to 1.5A current to a load.

The LM 317 is operated as a floating regulator because the adjustment terminal is not connected to ground; but floats to whatever voltage is across R_2 . This allows output to be much higher than that of a fixed voltage regulator.

Thus the output voltage is proportional to resistance R_2 . The output voltage can be made variable by making resistance R_2 variable and keeping R_1 fixed.

Thus by varying R_2 , output voltage can be adjusted. Typically I_{adj} is very small so generally neglected. $\therefore V_o = 1.25[1 + R_2/R_1]$

FIXED POSITIVE VOLTAGE REGULATORS

FIGURE 7: Fixed Voltage Regulators

The series 78 regulators provide fixed regulated voltages from 5 to 24 V shows how one such IC, a 7812, is connected to provide voltage regulation with the output from this unit of +12V Dec. An unregulated input voltage V_i is filtered by capacitor C_1 and connected to the IC's IN terminal.

BLOCK DIAGRAM OF POWER SUPPLY

The AC voltage, typically 220V RMS, is connected to a transformer, which steps that AC voltage down to the level of the desired DC output. A diode rectifier then provides a full-wave rectified voltage that is initially filtered by a simple capacitor filter to produce a DC voltage. This resulting DC voltage usually has some ripple or AC voltage variation.

A regulator circuit removes the ripples and also remains the same DC value even if the input DC voltage varies, or the load connected to the output DC voltage changes. This voltage regulation is usually obtained using one of the popular voltage regulator IC units.

FIGURE 8: Block Diagram of Power Supply

TRANSFORMER

The potential transformer will step down the power supply voltage (0-230V) to (0-6V) level. Then the secondary of the potential transformer will be connected to the precision rectifier, which is constructed with the help of op-amp. The advantages of using a precision rectifier are it will give a peak voltage output as DC, the rest of the circuits will give only RMS output.

The transformer in the simplest way can be described as a thing that steps up or steps down voltage. In a step-up transformer, the output voltage is increased and in a step-down transformer, the output voltage is decreased. The step-up transformer will decrease the output current and the step-down transformer will increase the output current for keeping the input and the output power of the system equal.

The transformer is basically a voltage control device that is used widely in the distribution and transmission of alternating current power. The idea of a transformer was first discussed by Michael Faraday in the year 1831 and was carried forward by many other prominent scientific scholars. However, the general purpose of using transformers was to maintain a balance between the electricity that was generated at very high voltages and consumption which was done at very low voltages.

A transformer is a passive component that transfers electrical energy from one electrical circuit to another circuit, or multiple circuits. According to Faraday's law, since the same magnetic flux passes through both the primary and secondary windings in an ideal transformer, a voltage is induced in each winding proportional to its number of windings. The transformer winding voltage ratio is equal to the winding turns ratio.

An ideal transformer is a reasonable approximation for a typical commercial transformer, with voltage ratio and winding turns ratio both being inversely proportional to the corresponding current ratio. The load impedance referred to the primary circuit is equal to the turns ratio squared times the secondary circuit load impedance. The ideal transformer model assumes that all flux generated by the primary winding links all the turns of every winding, including itself. In practice, some flux transverses paths that take it outside the windings. Such flux is termed leakage flux, and results in leakage inductance in series with the mutually coupled.

BRIDGE RECTIFIER

When four diodes are connected as shown in the figure, the circuit is called as a bridge rectifier. The input to the circuit is applied to the diagonally opposite corners of the network, and the output is taken from the remaining two corners.

Let us assume that the transformer is working properly and there is a positive potential, at point A and a negative potential at point B. The positive potential at point A will forward bias D3 and reverse bias D4. The negative potential at point B will forward bias D1 and reverse D2. At this time the D3 and D1 are forward biased and will allow current flow to pass through them; D4 and D2 are reverse biased and will block current flow. The path for current flow is from point B through D1, up through RL, through D3, through the secondary of the transformer back to point B.

This path is indicated by the solid arrows. Waveforms (1) and (2) can be observed across D1 and D3. One-half cycle later the polarity across the secondary of the transformer reverse, forward biasing D2 and D4 and reverse biasing D1 and D3.

The current flow will now be from point A through D4, up through RL, through D2, through the secondary of T1, and back to point A. This path is indicated by the broken arrows. Waveforms (3) and (4) can be observed across D2 and D4. The current flow through RL is always in the same direction. In flowing through RL this current develops a voltage corresponding to that shown waveform (5). Since current flows through the load (RL) during both half cycles of the applied voltage, this bridge rectifier is a full-wave rectifier. One advantage of a bridge rectifier over a conventional full-wave rectifier is that with a given transformer the bridge rectifier produces a voltage output that is nearly twice that of the conventional full-wave circuit.

Regulator IC units contain the circuitry for reference source, comparator amplifier, control device, and overload protection all in a single IC. IC units provide regulation of either a fixed positive voltage, a fixed negative voltage, or an adjustable set voltage. NODEMCU V3 FOR FAST IOT APPLICATION DEVELOPMENT

The best way to develop quickly an IoT application with less Integrated circuits to add is to choose this circuit “NodeMCU”.Today, we will give a detailed Introduction on NodeMCU V3. It is an open-source firmware and development kit that plays a vital role in designing a proper IoT product using a few script lines. The module is mainly based on ESP8266 that is a low-cost Wi-Fi microchip incorporating both a full TCP/IP stack and microcontroller capability. It is introduced by manufacturer Espressif Systems. The ESP8266 NodeMcu is a complex device, which combines some features of the ordinary Arduino board with the possibility of connecting to the internet.

Arduino Modules and Microcontrollers have always been a great choice to incorporate automation into the relevant project. But these modules come with a little drawback as they don't feature a built-in WiFi capability, subsequently, we need to add external WiFi protocol into these devices to make them compatible with the internet channel.

This is the famous NodeMCU which is based on ESP8266 WiFi SoC. This is version 3 and it is based on ESP-12E (An ESP8266 based WiFi module). NodeMCU is also an open-source firmware and development kit that helps you to prototype your IOT product within a few LUA script lines, and of course you can always program it with Arduino IDE. In this article, We will try present useful details related to this WiFi Development Kit, its main features, pinout and everything we need to know about this module and the application domain.

As Arduino.cc began developing new MCU boards based on non-AVR processors like the ARM/SAM MCU used in the Arduino Due, they needed to modify the Arduino IDE so it would be relatively easy to change the IDE to support alternate toolchains to allow Arduino C/C++ to be compiled for these new processors. They did this with the introduction of the Board Manager and the SAM Core.

Introduction NodeMCU V3

NodeMCU V3 is an open-source firmware and development kit that plays a vital role in designing an IoT product using a few script lines. Multiple GPIO pins on the board allow us to connect the board with other peripherals and are capable of generating PWM, I2C, SPI, and UART serial communications.

The interface of the module is mainly divided into two parts including both Firmware and Hardware where former runs on the ESP8266 Wi-Fi SoC and later is based on the ESP-12 module.

The firmware is based on Lua – A scripting language that is easy to learn, giving a simple programming environment layered with a fast scripting language that connects you with a well-known developer community. And open source firmware gives you the flexibility to edit, modify and rebuilt the existing module and keep changing the entire interface until you succeed in optimizing the module as per your requirements.

USB to UART converter is added on the module that helps in converting USB data to UART data which mainly understands the language of serial communication it with other embedded devices like Raspberry Pi. NodeMCU V3 Pinout

NodeMCU V3 comes with a number of GPIO Pins. Following figure shows the Pinout of the board.

FIGURE 9: NodeMCU V3 Pinout

There is a candid difference between Vin and VU where former is the regulated voltage that may stand somewhere between 7 to 12 V while later is the power voltage for USB that must be kept around 5 V.

- 6.Interactive and Programmable
- 7.ESP8266 with inbuilt wifi
- 8.USB to UART converter
- 9.GPIO pins
- 10.Arduino-like hardware IO
- 11.Advanced API for hardware IO, which can dramatically reduce the redundant work for configuring and manipulating hardware.
- 12.Code like arduino, but interactively in Lua script.
- 13.Nodejs style network API
- 14.Event-driven API for network applications, which facilitates developers writing code running on a 5mm*5mm sized MCU in Nodejs style.
- 15.Greatly speed up your IOT application developing process.
- 16.Lowest cost WI-FI
- 17.Less than \$2 WI-FI MCU ESP8266 integrated and easy to prototyping development kit.
- 18.We provide the best platform for IOT application development at the lowest cost.

As mentioned above, a cable supporting micro USB port is used to connect the board. As you connect the board with a computer, LED will flash. You may need some drivers to be installed on your computer if it fails to detect the NodeMCU board. You can download the driver from this [page](#).

Note: We use Arduino IDE software for programming this module. It is important to note that the pin configuration appearing on the board is different from the configuration we use to program the board on the software i.e. when we write code for targeting pin 16 on the Arduino IDE, it will actually help is laying out the communication with the D0 pin on the module.

Following figure the shows the pin configuration to use in Arduino IDE.

FIGURE 10: PIN CONFIGURATION TO USE IN ARDUINO IDE

How to Power NodeMCU V3

We can see from the pinout image above, there are five ground pins and three 3V3 pins on the board. The board can be powered up using the following three ways.

USB Power. It proves to an ideal choice for loading programs unless the project you aim to design requires separate interface i.e. disconnected from the computer.

Provide 3.3V. This is another great option to power up the module. If you have your own off-board regulator, you can generate an instant power source for your development kit.

Power Vin. This is a voltage regulator that comes with the ability to support up to 800 mA. It can handle somewhere between 7 to 12 V. You cannot power the devices operating at 3.3 V, as this regulator unable to generate as low as 3.3V.

BLUETOOTH HC-05 MODULE

In this Arduino Bluetooth Tutorial we will learn how use the HC-05 module for controlling Arduino via Bluetooth communication. You can watch the following video or read the written tutorial below for more details.

HC-05 Default Settings

Default Bluetooth Name: "HC-05"

Default Password: 1234 or 0000

Default Communication: Slave

Default Mode: Data Mode

Data Mode Baud Rate: 9600, 8, N, 1

Command Mode Baud Rate: 38400, 8, N, 1

Default firmware: LINVOR

HC-05 Technical Specifications

Serial Bluetooth module for Arduino and other microcontrollers

Operating Voltage: 4V to 6V (Typically +5V)

Operating Current: 30Ma

Range: <100m

Works with Serial communication (USART) and TTL compatible

Follows IEEE 802.15.1 standardized protocol

Uses Frequency-Hopping Spread spectrum (FHSS)

Can operate in Master, Slave or Master/Slave mode

Can be easily interfaced with Laptop or Mobile phones with Bluetooth

Supported baud rate: 9600,19200,38400,57600,115200,230400,460800.

Overview

For this tutorial I made two example, controlling the Arduino using a smartphone and controlling the Arduino using a laptop or a PC. In order not to overload this tutorial, in my next tutorial we will learn how we can configure the HC-05 Bluetooth module and make a Bluetooth communication between two separate Arduino Boards as master and slave devices

FIGURE 11: Bluetooth

Before we start with the first example, controlling an Arduino using a smartphone, let's take a closer look at the HC-05 Bluetooth module. Comparing it to the HC-06 module, which can only be set as a Slave, the HC-05 can be set as Master as well which enables making a communication between two separate Arduino Boards. There are several different versions

of this this module but I recommend the one that comes on a breakout board because in that way it's much easier to be connected. The HC-05 module is a Bluetooth SPP (Serial Port Protocol) module, which means it communicates with the Arduino via the Serial Communication.

Circuit Schematics

The particular module that I have can be powered from 3.6 to 6 volts, because it comes on breakout board which contains a voltage regulator. However, the logic voltage level of the data pins is 3.3V. So, the line between the Arduino TX (Transmit Pin, which has 5V output) and the Bluetooth module RX (Receive Pin, which supports only 3.3V) needs to be connected

Like BJTs, MOSFETs have three terminals, but this time they're named source (S), drain (D), and gate (G). And again, there are two different versions of the symbol, depending on whether you've got an n-channel or p-channel MOSFET. There are a number of commonly used symbols for each of the MOSFET types.

FIGURE 12: Bluetooth Connection

Description:

First we need to define the pin to which our LED will be connected and a variable in which we will store the data coming from the smartphone. In the setup section we need to define the LED pin as output and set it low right away. As mention previously, we will use the serial communication so we need to begin the serial communication at 38400 baud rate, which is the default baud rate of the Bluetooth module. In the loop section with the `Serial.available()` function we will check whether there is available data in the serial port to be read. This means that when we will send data to the Bluetooth module this statement will be true so then using the `Serial.read()` function we will read that data and put it into the

“state” variable. So if the Arduino receive the character ‘0’ it will turn the LED off and using the Serial.println() function it will send back to the smartphone, via the serial port, the String “LED: OFF”. Additionally we will reset the “state” variable to 0 so that the two above lines will be executed only once. Note here that the “state” variable is integer, so when we receive the character ‘0’ that comes from smartphone, the actual value of the integer “state” variable is 48, which corresponds to character ‘0’, according to the ASCII table. That’s why in the “if” statement we are comparing the “state” variable to a character ‘0’. On the other hand, if the received character is ‘1’, the LED will light up and the String “LED: ON” will be sent back.

Now the code is ready to be uploaded but in order to do that we need to unplug the TX and RX lines because when uploading the Arduino uses the serial communication so the pins RX (digital pin 0) and TX (digital pin1) are busy. We can avoid this step if we use the other TX and RX pins of the Arduino Board, but in that case we will have to use the Software Serial.h library for the serial communication

D.C MOTOR

The electrical motor is an instrument, which converts electrical energy into mechanical energy. According to faraday’s law of Electromagnetic induction, when a current carrying conductor is placed in a magnetic field, it experiences a mechanical force whose direction is given by Fleming’s left hand rule.

A DC motor is an electrical machine that converts electrical energy into mechanical energy. In a DC motor, the input electrical energy is the direct current which is transformed into the mechanical rotation. In this session, let us know what is a DC motor, types of DC motor and their applications.

FIGURE 13: DC Motor

Constructional a dc generator and a dc motor are identical. The same dc machine can be used as a generator or as a motor. When a generator is in operation, it is driven mechanically and develops a voltage. The voltage is capable of sending current through the load resistance. While motor action a torque is developed. A magnetic field arises in the air gap when the field coil of the DC motor is energised. The created magnetic field is in the direction of the radii of the armature. The magnetic field enters the armature from the North pole side of the field coil and “exits” the armature from the field coil’s South pole side. The torque can produce mechanical rotation. Motors are classified as series wound, shunt wound motors.

DC motors have a wide range of applications ranging from electric shavers to automobiles. To cater to this wide range of applications, they are classified into different types based on the field winding connections to the armature as:

Self Excited DC Motor

Separately Excited DC Motor

In self-excited DC motors, the field winding is connected either in series or parallel to the armature winding. Based on this, the self-excited DC motor can further be classified as:

Shunt wound DC motor

Series wound DC motor

Compound wound DC motor

A brushless DC motor, also known as synchronous DC motor, unlike brushed DC motors, do not have a commutator. The commutator in a brushless DC motor is replaced by an electronic servomechanism that can detect and adjust the angle of the rotor. A brushed DC motor features a commutator that reverses the current every half cycle and creates single direction torque. While brushed DC motors remain popular, many have been phased out for more efficient brushless models in recent years.

DC motor fans use 70% less energy than a standard AC fan.

DC motor fans are less noisy.

DC motor fans have more speed options than an AC motor fan.

PRINCIPLES OF OPERATION

The motor runs according to the principle of Fleming's left hand rule. When a current carrying conductor is placed in a magnetic field, a force is produced to move the conductor away from the magnetic field. The conductor carrying current to North and South poles is being removed.

FIGURE 14: THE BASIC PRINCIPLE OF MOTOR ACTION

ELECTROMAGNETS AND MOTORS:

To understand how an electric motor works, the key is to understand how the electromagnet works. An electromagnet is the basis of an electric motor. You can understand how things work in the motor by imagining the following scenario.

Say that you created a simple electromagnet by wrapping 100 loops of wire around a nail and connecting it to a battery. The nail would become a magnet and have a North and South Pole while the battery is connected. Now say that you take your nail electromagnet, run an axle through the middle of it, and you suspended it in the middle of a horseshoe magnet as shown in the figure below. If you were to attach a battery to the electromagnet so that the North end of the nail appeared as shown, the basic law of magnetism tells you what would happen. The North end of the electromagnet would be repelled from the north end of the horseshoe magnet and attracted to the south end of the horseshoe magnet.

An electromagnet is a type of magnet in which the magnetic field is produced by an electric current. Electromagnets usually consist of wire wound into a coil. A current through the wire creates a magnetic field which is concentrated in the hole in the center of the coil. The magnetic field disappears when the current is turned off. The wire turns are often wound around a magnetic core made from a ferromagnetic or ferrimagnetic material such as iron; the magnetic core concentrates the magnetic flux and makes a more powerful magnet. The main advantage of an electromagnet over a permanent magnet is that the

magnetic field can be quickly changed by controlling the amount of electric current in the winding. However, unlike a permanent magnet that needs no power, an electromagnet requires a continuous supply of current to maintain the magnetic field.

BRUSHES:

The brushes of a DC motor are made with graphite and carbon structure. These brushes conduct electric current from the external circuit to the rotating commutator. Hence, we come to understand that the commutator and the brush unit are concerned with transmitting the power from the static electrical circuit to the mechanically rotating region or the rotor. The brushes of a DC motor are made with graphite and carbon structure. These brushes conduct electric current from the external circuit to the rotating commutator. Brushes are vital to the efficiency and uptime of your DC and brushed AC motors because they are the electrical connection between the power source and the commutator. To effectively and efficiently transmit the electricity, brushes must have full, flat contact with the commutator at all times.

Brushed DC motors are used widely and frequently in home appliances and in automobiles ranging from toys to push-button for adjusting seats in cars. They are inexpensive, easy to use, and have different shapes and sizes. A BDC motor provides exact control of speed, driven by a direct current. This type of motor can supply three to four times more torque than it's rated torque and If needed, it even has the potential to supply up to five times more, without stalling. BDC Motors consist of six different components that we will elaborate on the most important ones in the following sections. BDC Motors by using rings to power a magnetic drive that conducts the motor's armature, provide stable and continuous current. This kind of motor is one of the earliest used motors and is commonly used because of the ability to vary the speed-torque ratio in almost any way. A BDC Motor is made up of two magnets facing the same direction, surrounding two coils of wire that lie in the middle of the Motor and around a rotor. The coils are set to face the magnets which causes electricity to flow to them. This builds a magnetic field, ultimately pushing the coils away from the magnets they are encountering which finally makes the rotor turn.

The current cut off at the rotor makes a turn of 180 degrees. This makes each rotor to face the opposite magnet. once the current starts over again, the electricity flows oppositely and

sends another pulse having the rotor turned once again. By transferring the electricity from the rotor, brushes that exist within the motor turn it off and on.

PUTTING IT ALL TOGETHER:

When you put all of these parts together, what you have is a complete electric motor.

FIGURE 15: The armature winding

In this figure, the armature winding has been left out so that it is easier to see the commutator in action. The key thing to notice is that as the armature passes through the horizontal position, the poles of the electromagnet flip.

Because of the flip, the North Pole of the electromagnet is always above the axle so it can repel the field magnet's North Pole and attract the field magnet's South Pole.

If you ever take apart an electric motor you will find that it contains the same pieces described above: two small permanent magnets, a commutator, two brushes and an electromagnet made by winding wire around a piece of metal. Almost always, however, the rotor will have three poles rather than the two poles as shown in this article. There are two good reasons for a motor to have three poles:

TYPES OF DC MOTORS REQUIRE NO COMMUTATION:

Homopolar motor – A homopolar motor has a magnetic field along the axis of rotation and an electric current that at some point is not parallel to the magnetic field. The name homopolar refers to the absence of polarity change.

PERMANENT MAGNETIC MOTOR

Main article: Permanent-magnet electric motor

A PM motor does not have a field winding on the stator frame, instead relying on PMs to provide the magnetic field against which the rotor field interacts to produce torque. Compensating windings in series with the armature may be used on large motors to improve commutation under load. Because this field is fixed, it cannot be adjusted for speed control.

However, large PMs are costly, as well as dangerous and difficult to assemble; this favors wound fields for large machines.

Permanent magnet motors are more efficient than induction motor or motors with field windings for certain high-efficiency applications such as electric vehicles. Tesla's chief motor designer was quoted discussing these advantages, saying:

It's well known that permanent magnet machines have the benefit of pre-excitation from the magnets, and therefore you have some efficiency benefit for that. Induction machines have perfect flux regulation and therefore you can optimize your efficiency. Both make sense for variable-speed drive single-gear transmission as the drive units of the cars. So, as you know, our Model 3 has a permanent magnet machine now. This is because for the specification of the performance and efficiency, the permanent magnet machine better solved our cost minimization function, and it was optimal for the range and performance target. Quantitatively, the difference is what drives the future of the machine, and it's a trade-off between motor cost, range and battery cost that is determining which technology will be used in the future.

Permanent magnet motors are more efficient than induction motor or motors with field windings for certain high-efficiency applications such as electric vehicles. Tesla's chief motor designer was quoted discussing these advantages.

WOUND STATOR

A field coil may be connected in shunt, in series, or in compound with the armature of a DC machine (motor or generator). The stator of a wound rotor motor is the same as a typical induction motor, but the rotor has a three-phase winding, with each of the winding terminals connected to separate slip rings. In contrast, a traditional induction motor (aka "squirrel cage motor") has windings that are permanently short-circuited by an end ring.

The slip rings on the wound rotor motor contain brushes that form an external, secondary circuit into which impedance (resistance) can be inserted. During starting, this resistance is placed in series with the rotor windings. This added resistance causes the rotor current to run more in phase with the stator current, which increases the torque that is developed. But added resistance also decreases the current in the secondary circuit, so a very high starting torque can be produced with low starting current.

SERIES CONNECTION

A series DC motor connects the armature and field windings in series with a common D.C. power source. A series motor has very high starting torque and is commonly used for starting high inertia loads, such as trains, elevators or hoists. This speed/torque characteristic is useful in applications such as dragline excavators, where the digging tool moves rapidly when unloaded but slowly when carrying a heavy load.

SHUNT CONNECTION

A shunt DC motor connects the armature and field windings in parallel or shunt with a common D.C. power source. This type of motor has good speed regulation even as the load varies, but does not have the starting torque of a series DC motor. It is typically used for industrial, adjustable speed applications, such as machine tools, winding/unwinding machines and tensioners. A gas-filled tube can also be used as a shunt, particularly in a lightning arrester. Neon and other noble gases have a high breakdown voltage, so that normally current will not flow across it. However, a direct lightning strike (such as on a radio tower antenna) will cause the shunt to arc and conduct the massive amount of electricity to ground, protecting transmitters and other equipment.

Another older form of lightning arrester employs a simple narrow spark gap, over which an arc will jump when a high voltage is present. While this is a low cost solution, its high triggering voltage offers almost no protection for modern solid-state electronic devices powered by the protected circuit.

L293D MOTOR DRIVER IC

FIGURE 16: L293D IC

L293D H-bridge driver is the most commonly used driver for Bidirectional motor driving applications. This L293D IC allows DC motor to drive on either direction. L293D is a 16-pin IC which can control a set of two DC motors simultaneously in any direction. It means that you can control two DC motor with a single L293D IC. Because it has two H- Bridge Circuit inside. The L293D can drive small and quiet big motors as well. There are various ways of making H-bridge motor control circuit such as using transistor, relays and using L293D/L298. Before going into detail, first we will see what is H-Bridge circuit.

L293D bridge motor driver IC Pin out and Working:

There are 4 input pins for l293d, pin 2,7 on the left and pin 15 ,10 on the right as shown on the pin diagram. Left input pins will regulate the rotation of motor connected across left side and right input for motor on the right-hand side. The motors are rotated on the basis of the inputs provided across the input pins as LOGIC 0 or LOGIC 1. In simple you need to provide Logic 0 or 1 across the input pins for rotating the motor.

The right-hand rule was invented in the 19th century and it shows that we can produce current by combining the magnetic field and motion by following some specific rules. It also shows that we can produce the magnetic field and motion by combining one of each with the current.

After the invention of right-hand rule, a DC motor was invented by British scientist William Sturgeon. The DC motor was the first motor used by the scientist to convert the electric current to rotatory motion. DC Motor in the late 19th century has its own use but after the discovery of AC motor by Nikola Tesla and a wide amount of usage of AC current in industry and houses. The usage of AC motor became very much popular in the 20th century. But after the invention of the ICs DC motor again start gaining its popularity. The L293D is quadruple high-current half-H drivers. It is designed to provide bidirectional drive currents of up to 600-mA at voltages from 4.5 V to 36 V. Both devices are designed to drive inductive loads such as relays, solenoids, dc and bipolar stepping motors, as well as other high-current/high-voltage loads in positive-supply applications. All inputs are TTL compatible. Each output is a complete totem-pole drive circuit, with a Darlington transistor sink and a pseudo- Darlington source. Drivers are enabled in pairs, with drivers 1 and 2 enabled by 1,2EN and drivers 3 and 4 enabled by 3,4EN. When an enable input is high, the associated drivers are enabled, and their outputs are active and in phase with their inputs.

When the enable input is low, those drivers are disabled, and their outputs are off and in the high-impedance state. With the proper data inputs, each pair of drivers forms a full-H (or bridge) reversible drive suitable for solenoid or motor applications.

L293D Logic Table

Let's consider a Motor connected on left side output pins (pin 3,6). For rotating the motor in clockwise direction, the input pins have to be provided with Logic 1 and Logic 0.

Pin 2 = Logic 1 and Pin 7 = Logic 0 | Clockwise Direction

Pin 2 = Logic 0 and Pin 7 = Logic 1 | Anticlockwise Direction

Pin 2 = Logic 0 and Pin 7 = Logic 0 | Idle [No rotation] [Hi-Impedance state]

Pin 2 = Logic 1 and Pin 7 = Logic 1 | Idle [No rotation]

CONCLUSION

We are presenting the Wireless Power Transmission. As the electric vehicle in the market is increasing. We can use the wireless charging system to charge our vehicles. This system shows the efficiency and implementation of the charging station in future technology. According to the review, many researchers are becoming more interested in the design

features of powertrains and EMSs for hybrid and electric vehicles. To address control goals such as decreasing fuel consumption and emissions, preserving ESS charges, and increasing drivability and vehicle performance, many topologies for powertrains and associated EMSs have been suggested. In creating energy management techniques, there is a trade-off between optimality and execution. Experimental results showed that significant improvements in terms of power-transfer efficiency have been achieved. It was described and demonstrated that resonant inductive coupling can be used to deliver power wirelessly from a source coil to a load coil and charge a low power device. We can also select voltage variations by using variable resistor. As it was mentioned earlier, wireless charging could be the next big thing. In phase ii I submit this project in hardware and show the result.

INTRODUCTION

Precise positioning and tracking of people, things, or animals allows for the provisioning of a number of sophisticated services, like the automatic execution of a task(s) triggered by events, like a person passing a particular location in the area, or commercial or recreational applications needing location data inside a specific area, among other things. The potential to implement cutting-edge communication services and applications backed by position data on individuals and objects has emerged in recent years. Simultaneously, these systems' evolution has been continuously aided by the development of internet of things (IoT) technologies, such as radio frequency identification systems and Bluetooth and its variations, which are specifically designed for low-cost, short-range radio transmission. The development of short-range radio-based localization systems Technology is not a simple undertaking. In actuality, a variety of factors, including building materials, nearby objects, people's presence, etc., affect how radio waves propagate within buildings. The quality of the signal that is received might be affected by all of these factors.

AREA OF PROJECT

Precision tracking and data fusion capabilities are entering a new age with the introduction of next-generation indoor localization systems. The use of Bluetooth Low Energy (BLE) iBeacon technology, which provides unmatched benefits for real-time tracking and data fusion in interior spaces, is at the vanguard of this technological revolution. These cutting-edge solutions make it possible to precisely locate and monitor people, objects, and animals within indoor environments by utilizing the power of iBeacon modules. The solution creates a strong foundation for real-time tracking through a network of thoughtfully placed iBeacon devices, making asset monitoring and navigation inside intricate indoor environments effortless. Additionally, these systems improve the precision and dependability of tracking data by integrating advanced data fusion techniques including sensor integration and machine learning algorithms, offering useful insights for a wide range of applications. The next-generation indoor localization systems with BLE iBeacon technology represent a paradigm shift in indoor tracking and data fusion capabilities, opening up a plethora of opportunities for innovation and advancement, from improving safety and security measures to optimizing operational efficiency in commercial environments. Furthermore, by integrating advanced data fusion techniques, like machine learning algorithms and sensor integration, these systems improve the precision and dependability of tracking data, offering useful insights for a wide range of applications. With the help of BLE iBeacon technology, next-generation indoor localization systems can improve safety and security measures and optimize operational efficiency in commercial environments. This represents a paradigm shift in indoor tracking and data fusion capabilities and opens up a world of possibilities for innovation and advancement.

IBEAON REAL-TIME TRACKING AND DATA FUSION

This Arduino sketch configures a Bluetooth Low Energy (BLE) scanner to find nearby beacons. The sketch retrieves the address, UUID, name, and signal strength (RSSI) of each beacon it finds. It then determines whether the detected device matches predefined addresses that correspond to different floors. If it does, the sketch sends the device details over serial communication to another device, most likely a microcontroller or computer, for additional processing or monitoring. The sketch repeats this scanning process indefinitely

in the main loop, allowing real-time monitoring of BLE beacons in range. In summary, this sketch enables communication between the ESP32 and an external server over WiFi, facilitating IoT applications and data exchange. This PHP script serves as requests containing data from a BLE scanner.

BLUETOOTH AND BEACON NAVIGATION

The integration of Bluetooth Low Energy (BLE) iBeacon technology into next-generation indoor localization systems represents a significant leap forward in real-time tracking and data fusion capabilities. By deploying iBeacons throughout indoor environments, such as shopping malls, airports, or warehouses, these systems can accurately track the movements of individuals or assets in real-time. Leveraging BLE connectivity, iBeacons communicate with smartphones or other BLE-enabled devices, facilitating seamless positioning and navigation within indoor spaces where GPS signals may be unreliable. Through data fusion techniques, the system combines information from multiple iBeacons to triangulate the precise location of a device, enhancing accuracy. This technology finds applications across industries, from retail and healthcare to logistics and hospitality, offering improved efficiency, personalized experiences, and cost-effective scalability.

BEACON LOCALIZATION TECHNIQUES

When it comes to next-generation indoor localization systems that utilize BLE iBeacon technology, a number of beacon localization strategies are essential to obtaining robust data fusion capabilities and real-time tracking. Basic techniques used to determine a device's precise location inside an enclosed space include trilateration and multilateration. Using trilateration, the position of the device is determined by measuring its distance from three or more known iBeacon locations. Proximity is determined via signal strength measurements. By adding other variables like signal time or angle of arrival, multilateration improves on this and allows for more precise localization even in intricate interior designs. Furthermore, in order to match observed signal patterns and deduce device location, fingerprinting algorithms make use of pre-existing maps, or "fingerprints," of signal intensity at various points in the interior area. These methods, in conjunction with sensor fusion techniques that incorporate data from gyroscopes, accelerometers, and other sensors,

add up to a comprehensive indoor localization solution that can facilitate seamless data fusion for improved user experiences and operational efficiency, as well as precise real-time tracking.

LITERATURE REVIEW

C. Joseph et al. proposed a Bluetooth beacon-based person monitoring system for indoor navigation without additional sensors. BLE beacons broadcast signals, while beacon receivers track locations using changes in signal strength. An ESP32 serves as a transceiver to pinpoint Bluetooth transmitters. The system enables location tracking via an application accessible to authorized users. This initiative offers discreet indoor navigation, enhancing user convenience and privacy.

W. Zhao et al. investigated the Range-Only Single-Beacon (ROSB) technology for AUV localization. Unlike traditional LBL methods requiring multiple acoustic beacons, ROSB significantly reduces deployment time and labor with just one beacon. Addressing ROSB's initial observation limitations, an algorithm incorporating a virtual beacon and adjustment theory is proposed. The proposed algorithm enhances ROSB's accuracy by integrating a virtual beacon and adjustment theory, effectively mitigating its initial observation limitations while streamlining AUV localization processes. Furthermore, the algorithm's optimization ensures robust AUV localization, overcoming initial observation limitations and maximizing efficiency, making ROSB technology a promising solution for underwater positioning in various applications. This algorithm enhances ROSB's accuracy, mitigating observation limitations and streamlining AUV localization processes for efficient underwater positioning solutions.

Obreja and Vulpe Evaluating an indoor localization solution using Bluetooth Low Energy beacons. Obreja and Vulpe (2020) assess the solution's accuracy under various scenarios including changes in transmission power, sample sizes, and beacon quantities. They emphasize Bluetooth Low Energy's advantages in accuracy and energy efficiency. This survey contributes to understanding the effectiveness of beacon-based indoor localization systems, crucial for location-based services development. Furthermore, evaluation contributes significantly to the understanding of beacon-based indoor localization systems, which are essential for the development of location-based services (LBS). By accurately assessing the performance of the localization solution under various conditions.

S. Gupta et al. discussed the "Indoor Localization Using Bluetooth Low Energy (BLE) Beacons and Particle Filtering." The research investigates the application of particle filtering algorithms for indoor localization with BLE beacons, focusing on enhancing accuracy and reliability. The study explores the potential of particle filtering in improving the localization accuracy of BLE beacon-based systems by dynamically estimating the position of users or assets within indoor environments. By incorporating information from multiple sources, including signal strength measurements, beacon locations, and motion sensors. By integrating particle filtering algorithms, the study aims to create a robust indoor localization system capable of accurately tracking users or assets within indoor spaces, thereby advancing the practical applications of BLE beacon technology in various industries.

G. Wang et al. proposed that "Indoor Localization with BLE Beacons and Inertial Sensors Fusion." Addressing the limitations of standalone BLE beacon systems, this study integrates inertial sensors with BLE beacons for indoor localization, aiming to enhance accuracy and reliability in dynamic environments. By combining data from BLE beacons and inertial sensors, Wang et al. (2019) strive to create a robust indoor localization system capable of accurately tracking individuals or assets in dynamic environments. This integration leverages the strengths of both technologies, enhancing accuracy, reliability, and adaptability to varying indoor conditions and user movements. The integration of inertial sensors with BLE beacons aims to enhance accuracy, reliability, and adaptability in dynamic indoor environments. This fusion of technologies leverages the strengths of both systems, promising improved indoor localization capabilities, as it can seamlessly transition between different localization modes based on the availability of signals and the reliability of sensor

measurements. This adaptability ensures consistent performance across various indoor environments, including crowded spaces, multi-floor buildings, or areas with limited beacon coverage.

RELATED WORKS

Several noteworthy research initiatives have surfaced in the field of next-generation indoor localization systems that use BLE iBeacon technology for real-time tracking and data fusion. An analysis of BLE beacon technologies provides information on indoor localization strategies that make use of angle of arrival (AoA), time of flight (ToF), and signal strength-based approaches. Novel strategies including integrating particle filtering techniques with BLE beacons and machine learning models with beacon data and inertial sensors have been investigated to improve localization accuracy and robustness. Furthermore, cooperative simultaneous localization and mapping (SLAM) frameworks that make use of BLE beacons have demonstrated potential in facilitating distributed mapping and localization across various devices. Differential privacy techniques have been researched to address privacy concerns and maintain user privacy while facilitating efficient monitoring and merging data. Energy-efficient localization systems are further aided by initiatives to optimize energy consumption in BLE beacon networks through the use of duty cycling techniques. Together, these studies push the boundaries of indoor localization and aim to provide reliable, precise, and privacy-preserving real-time tracking and data fusion in indoor settings. As technology progresses, there is an increasing focus on resolving real-world issues related to the scalability and deployment of next-generation indoor localization systems using BLE iBeacon technology. In an effort to simplify the integration of dynamic interior settings with current infrastructure, research has focused on distributed localization and mapping techniques. Additionally, by investigating cooperative localization strategies, localization accuracy and dependability are increased by utilizing the combined intelligence of networked devices. Energy efficiency remains a paramount concern, prompting investigations into novel power-saving mechanisms and optimization algorithms tailored for BLE beacon networks. Additionally, the integration of privacy-preserving measures, such as differential privacy, underscores the importance of safeguarding user data in indoor localization applications. By tackling these challenges head-on, researchers strive to cultivate

robust, scalable, and privacy-conscious indoor localization solutions that empower diverse industries and enrich user experiences in indoor spaces.

METHODOLOGY

When attempting to offer a comprehensive user experience in certain settings, like museums, the placement of people indoors is a crucial subject. In this study, we proposed a comprehensive indoor localization system for humans. The transmitter and the receivers use BLE technology in accordance with the system architecture under consideration. The gathered data are then transmitted via WiFi, taking advantage of the MQTT protocol, to a data repository. After the data have been sorted and filtered, a localizer uses the NLS technique to estimate the transmitter's position. We conducted a measurement campaign to characterize the environment, and we trained a neural network with the collected data. We also modeled the antennas on the receivers. We also thought about a few deployment tactics for the receivers in the museum space. The position estimate's precision was about two meters, but with more BLE receivers, it might be as low as one Electronics 2020, 9, 1055 18, or 20 meters. Lastly, we assessed the effect of the obstruction brought on by the large number of visitors to the museum. A more thorough investigation of human blockage may be explored as a future development of this work, for instance by attempting to assess a person's presence using a different neural network. The RSSI might be dynamically measured using this neural network. Thus, the receiver can be appropriately used in the location estimate rather than being discarded when a human barrier is discovered.⁵

MODULES DESCRIPTION

BLE iBeacons are small, low-cost devices that emit Bluetooth signals, enabling them to serve as location markers within indoor environments. By strategically deploying these beacons throughout indoor spaces, Next-Gen Indoor Localization Systems can triangulate the position of user devices based on signal strength and proximity, providing accurate LOCATION information in real time. SOFTWARE SETUP

XAMPP is a free and open-source cross-platform web server solution stack package developed by Apache Friends as shown in fig 4.5 . It consists of Apache HTTP Server, MariaDB database (formerly MySQL), and interpreters for scripting languages such as PHP and Perl. MySQL, one of the components of XAMPP, is a popular relational database management system used for storing and retrieving data in various web applications.

XAMPP SERVER

MySQL in XAMPP provides users with a robust and user-friendly database management system for developing and testing dynamic web applications locally. With MySQL, developers can create databases, tables, and execute SQL queries to manipulate data efficiently. It supports standard SQL syntax, making it compatible with a wide range of web development frameworks and tools. In addition to its ease of use, MySQL in XAMPP offers features such as transaction support, indexing, and stored procedures, enhancing the performance and scalability of web applications. With XAMPP's bundled setup, developers can quickly set up a local development environment with Apache, PHP, and MySQL, facilitating rapid prototyping, testing, and debugging of web applications before deployment to production servers.

MYSQL DATABASE

MySQL is a relational database management system (RDBMS) renowned for its robustness and flexibility in handling structured data. Developed by Oracle Corporation, MySQL is open-source, making it accessible to a broad user base, from individual developers

to large enterprises. Its versatility allows it to power a wide range of applications. MySQL's rich feature set includes support for transactions, stored procedures, triggers, and views, enabling developers to build sophisticated database-driven applications. Its compatibility with various programming languages and frameworks further enhances its usability and integration capabilities. Additionally, help safeguard sensitive data from unauthorized access and breaches. MySQL benefits from a vibrant community of developers and users who contribute to its ongoing development and provide support through forums, documentation, and tutorials. One of MySQL's key strengths lies in its scalability, making it suitable for both small-scale projects and large-scale deployments. Whether managing a few hundred records or handling millions of data entries, MySQL offers performance optimizations and clustering options to meet varying workload demands as shown in fig. Additionally, MySQL's multi-threaded architecture and support for caching mechanisms enhance its ability to handle concurrent requests efficiently.

OVERALL OUTPUT OF SYSTEM

This PHP script functions as an endpoint to handle incoming HTTP GET requests containing data from a BLE (Bluetooth Low Energy) scanner. Upon receiving a request, typically via the `\$_GET` superglobal array, the script retrieves the device details such as address, UUID, name, and RSSI (Received Signal Strength Indication) from the request parameters. These parameters are essential for identifying and characterizing the BLE devices being scanned. Subsequently, the script utilizes this extracted data to insert a new record into a MySQL database table. This table serves as a repository for storing the collected data, enabling subsequent analysis or processing. 44 The insertion process involves SQL queries executed through PHP's MySQLi or PDO extension, ensuring secure interaction with the database. Following the insertion process, the script evaluates the success of the

operation. If the insertion is successful, it echoes a confirmation message affirming the successful addition of the data into the database. Conversely, if an error occurs during the insertion process, the script displays an error message, providing diagnostic information to aid in troubleshooting. Finally, to ensure proper resource management and mitigate potential security risks, the script closes the connection to the MySQL database.

CONCLUSION AND FUTURE WORK

Using Bluetooth Low Energy (BLE) iBeacon technology to construct a next-generation indoor localization system delivers notable improvements in real-time tracking and data fusion capabilities. We have investigated how BLE iBeacons can improve indoor locating accuracy, get beyond the drawbacks of conventional techniques, and enable a wide range of industry applications throughout this study. Furthermore, the integration of BLE iBeacon technology with data fusion techniques improves the indoor localization systems' resilience and dependability. Through the integration of data from many sources, including magnetic field mapping, Wi-Fi signals, and inertial sensors, the system can effectively reduce errors and deliver more precise positioning data—even in demanding settings. In addition, BLE iBeacon technology's scalability and adaptability make it appropriate for a variety of uses beyond conventional indoor placement. Potential use cases range widely, offering transformative benefits across multiple sectors, from healthcare monitoring and smart building management to retail analytics and proximity marketing. Going forward, there are a lot of chances for more research and development in the field of next-generation indoor localization systems that make use of BLE iBeacon technology. Improving indoor positioning algorithms' accuracy and precision is a major area of future research. Combining complementary location technologies like computer vision, LiDAR, and ultra-wideband

(UWB) with BLE iBeacon technology is another exciting path. The performance of indoor positioning could be greatly improved by examining the synergy between various modalities and creating hybrid localization systems, especially in intricate and dynamic indoor environments.

ABSTRACT

The objective of this research is to investigate the performance enhancement of a brushless DC motor that has been integrated with a power converter and controlled by an ANFIS. ANFIS, an acronym for Adaptive Neuro-Fuzzy Inference System, is a hybrid intelligent system that combines the benefits of both fuzzy logic and neural networks to provide an optimized control approach for various applications. The integrated system is expected to achieve improved efficiency, reliability, and accuracy compared to traditional control methods. The experimental setup involves implementing the ANFIS controller to regulate the motor speed and torque, and evaluating the performance metrics such as rise time, settling time, overshoot, and steady-state error. The study's outcomes may offer valuable understandings regarding the viability and efficiency of employing ANFIS-based control in brushless DC motor drive systems powered by converters, facilitated through Matlab/Simulink Software.

INTRODUCTION

Owing to their versatility in control techniques and broad speed regulation range, brushless DC motors (BLDCMs) find extensive application across various domains including electrical tools, electric vehicles, precise servos, and aerospace. Power converters are indispensable elements of BLDCM drive systems as they facilitate the connection

between the power supply and the brushless DC motor, Ensuring consistent voltage levels and balanced power distribution. Consequently,enhancing the entire efficiency of brushless DC motor (BLDCM) drive systems necessitates the creation of suitable power converter architecture and control mechanisms.

There are several power converter topologies available for BLDCM SSDs. Numerous rectifier schemes are designed to generate the dc-link voltage for BLDCM drives powered by ac grid. Although the large capacitor in the DC-link and the rectifier bridge at the front-end are widely used, this converter may produce a significantly Poor power factor and significant overall harmonic aberrations within the current from the AC source. Consequently, various converter configurations incorporating power factor correction (PFC) features have been developed to enhance the quality of alternating current (AC)mains. There are other types of converters, such as bridgeless Cuk and Luo, boost PFC, Cuk, Zata,and bridgeless canonical switching cells. Typically, the DC source, whether it be a battery bank or a solar PV system, is utilized. In battery-powered BLDCM drives,instead of using DC-DC converters, front-end step-down converters and Step-up/down converters are commonly employed. Alternatively, The Z-source-based VSI can be employed. Reducing copper/iron loss and improving current/torque performance are two benefits of Regulating the direct current (DC) link voltage of the voltage source inverter (VSI) within a front-end system based on a buck converter to adjust torque or speed. For high-speed BLDCM applications, this converter structure is therefore more appropriate.

Fig.1. Power converter for BLDCM drive based on front-end BBD converter.

As depicted in Figure 1, a typical TVSI equipped Bidirectional DC-DC converter at the front end capable of both stepping up and stepping down voltage (TVSI-BBD) has the capability to augment the voltage of the DC bus of the TVSI while handling the bidirectional flow of power between the battery and motor drive. In this setup, it is possible to decrease

the serial number of the battery bank. Thus, this method is well-suited for electric vehicle applications powered by batteries. To Construct the second BBD converter entails incorporating two extra power switches and an auxiliary drive circuit, resulting in entire system expenses, larger volume, and increased difficulty. A potential approach is to create a centralized power converter architecture with typical power switches and dynamic control mechanisms. A total of three Triple-switch legs have the capability of being interconnected simultaneously to make a converter featuring nine switches and dual outputs through utilizing an adjoining intermediate switch attached to each triple-switch bridge leg. This design presents an affordable and portable solution for a simultaneous three-phase load system, featuring compact nine-switch inverters governing a dual-motor drive. Compared to conventional topologies, this inverter provides fewer power switches, Improved voltage surge gain, decreased size of the output power filtering, and improved power efficiency.

The primary innovation of this research lies in the development of a compact integrated power converter design capable of boosting DC Link Voltage, along with its associated control method for a battery-operated Brushless DC motor drive system. In the proposed converter, a triple-switch leg serves as a critical link between the Buck-Boost-Diode converter and the Three Phase voltage source Inverter. In contrast to a typical TVSI-BBD converter, utilizing a novel field-oriented control (FOC) technique allows for the reduction of half of the power regulators and drive circuits needed for the DC-DC converter component. This approach achieves consistent voltage amplification and closed-loop speed control by decoupling the operation of the DC-DC converter from the TVSI. In addition to regulating the motor's speed and torque using the ANFIS controller, it involves evaluating performance metrics Parameters such as rise time, settling time, overshoot, and steady-state error. The outcomes of the research may shed light on the viability and efficiency of employing ANFIS-based control for brushless DC motor drive systems that feature power converters.

CONFIGURATION AND MANAGEMENT OF THE INTEGRATED CONVERTER

Design of the Proposed Converter

The proposed converter integrates the BBD converter with the TVSI's one phase bridge leg using a three switch leg, as illustrated in Figure. 2. By incorporating just one more power

transistor, the three-switch leg has the capability to connect both the battery supply and the A-phase coil concurrently. When compared to the typical two-stage design shown in Figure. 1, the proposed architecture saves half of the power switches. This has the benefit of lowering converter size while enhancing power density.

Figure.2. Power converter integrated within BLDC drives.

Principle of operation for the Three-Switch Leg

The three-switch leg is capable of linking the direct current supply and the BLDCM drive via terminals N and M, respectively, as depicted in Figure 2. Activate any two of the three power switches, and subsequently deactivate the third switch, to avoid terminal floating and potential bus voltage surges. This action results in three potential switching conditions, as illustrated in Figure. 3.

Figure.3. Operational conditions of the integrated three-switch leg.

TABLE 1

current via each power switch and the Voltage across the terminals in three potential switching states.

State	T_1	T_7	T_4	U_M	U_N	I_{T1}	I_{T7}	I_{T4}
1	On	Off	On	U_{dc}	0	i_a	0	I_L

2	Off	On	On	0	0	0	$-i_a$	I_{L-}
3	On	On	Off	U_{dc}	U_{dc}	i_a- I_L	$-I_L$	0

The current passes via each electrical switch, and the voltages at the both M and N contacts may be determined, as depicted in Figure. 3 and Table I. As illustrated in Figure. 2, Vbat-L-T4-T* can build an identical BBD cell to collaborate the power supply if T1 and T7 are considered a common switch (T*). In a similar vein, the T1-T# can be regarded as an analogous A-phase segment of the TVSI bridge if T7 and T4 are regarded as a single common switch T#. When the triple-switch leg functions in any of the three operational modes, it becomes feasible to autonomously regulate the BBD cell and the TVSI.

Modulation technique utilized by the Integrated Converter

The three-switch leg's modulation method needs to be altered in order to prevent incorrect switching states. The comparable three-phase inverter's A-phase control reference signal is positioned below the control reference for the corresponding BBD converter, as depicted

in Figure.4.

Figure.4. Diagram outlining the principles of modulation strategies.

This restriction allows for the generation of only three switching states, as shown in Figure.3, which can guarantee the three-switch leg's practicable operation.

Figure 4 illustrates that the boost duty cycle represented by D exceeds the reference signal for controlling BLDCM denoted as Ctr_A. Using the guidelines in (1), the upper and lower power transistors control signals are produced. These signals can be,

$$g_1 = \{ 1 (S_{carrier} \geq Ctr_a) 0 (S_{carrier} < Ctr_a) \quad \text{and} \quad g_4 = \{ 1 (D \geq S_{carrier}) 0 (D < S_{carrier}) \} \quad (1)$$

g_1 and g_4 serve as the signals that drive the gates of T1 & T4 respectively, while $S_{carrier}$ functions as the carrier signal.

The control signal for the mutually utilized switch T7 can be derived by calculating the three different switching configurations outlined in Table I.

$$g_7 = \underline{g_1 \& g_4} \quad (2)$$

It should be mentioned that, during the same switching period, switches S7, the shared power switch, commutates twice as often as switches S1 and S4. The three-phase control references are symmetrically spaced 120° apart in terms of electric angle. As a result, the logics listed below can be utilized to provide control signals for the power transistors within the B and C phase circuits.

$$g_3 = \underline{g_6} = \{ 1 (S_{carrier} \geq Ctr_b) 0 (S_{carrier} < Ctr_b) \quad \text{and} \quad g_5 = \underline{g_2} = \{ 1 (S_{carrier} \geq Ctr_c) 0 (S_{carrier} < Ctr_c) \} \quad (3)$$

Here, g_2, g_5, g_3 , and g_6 represent the gate-driving signals for transistors T2, T5, T3, and T6 respectively. Additionally, Ctr_b and Ctr_c denote the reference signals for controlling BLDCM of B and C Phases correspondingly.

Main control algorithm for the BLDCM drive integrated with the converter

To guarantee the reliability of the BLDCM drive integrated with the converter, it is recommended to segregate the ramping of DC bus voltage and the operational controls of the Brushless DC motor from the previously mentioned pulse width modulation (PWM) method. The FOC algorithm calculates the duty ratio for boosting (D) and the reference for controlling the Brushless DC motor. Ctr_a - Ctr_c to implement the modulation technique. The following three components make up the overall control algorithm, as seen in Figure. 5.

1. Control segment of the BBD: The corresponding Buck-Boost DC-DC Converter bridge arm will be built by T4 and T*, as the converter topology shows. A control architecture that

generates the modulation reference D and has an inner current loop in addition to an outer voltage loop is chosen to stabilize the dc bus voltage.

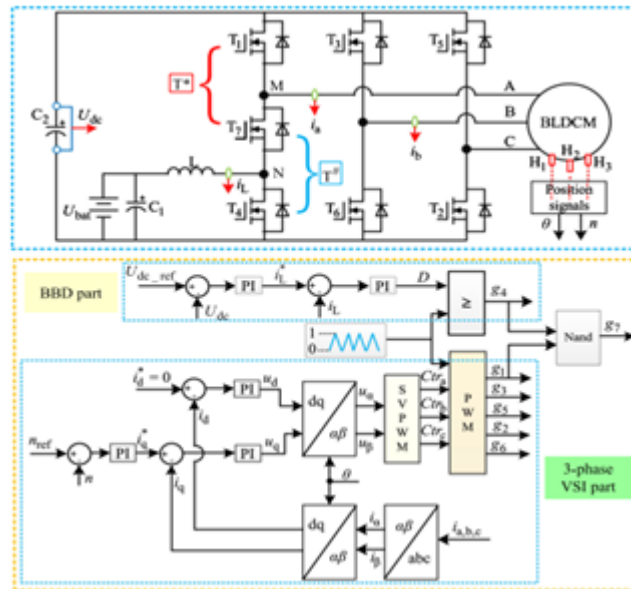

Figure.5. Block diagram illustrating the main control methodologies.

2.TVSI control part: T1-T#, T3-T6, and T5-T2 will build BLDC to the corresponding TVSI for BLDC drive control in the integrated topology. This study presents a space vector pulse width modulation (SVPWM) approach to BLDCM driving control that employs the typical $i_d = 0$ FOC algorithm. The measured two-phase current is used to calculate the currents along the direct and quadrature axes, denoted as i_d and i_q , as seen in Figure. 5, using Clark and Park transformations. A proportional-integral (PI) regulator has been added to enable robust closed-loop regulation of the rotor speed into an external rotor speed loop. This regulator generates the current reference i_q^* for tracking. PI controllers are used to regulate the i_d and i_q in order to produce the voltages in the direct and quadrature axes, represented as u_d and u_q . For SVPWM control, u_α and u_β values can be acquired by inverse Park transformation. The three control references C_{tra} - C_{trc} can be obtained using the SVPWM technique. One may acquire the gate-driving signals for T1, T3-T6, and T5-T2 based on the modulation logics described in (1) and (3)

3.Management of the shared power switch T7: T1 and T4's gate-driving signals are acquired in accordance with (1). Thus, (2) can be used to directly extract the gate-driving signal of T7.

CONCLUSION

Based on the facts provided, it is possible to deduce that using an ANFIS controller for a brushless DC motor with an integrated power converter can lead to enhanced performance. The ANFIS controller optimizes motor control by combining fuzzy logic and neural network approaches, resulting in smoother operation, increased efficiency, and improved accuracy. The incorporation of the power converter streamlines the control system while lowering overall cost and complexity. However, the system's actual performance will be determined by a variety of factors, including the specific motor and controller employed, operating conditions, and application requirements. More research and testing are needed to determine the efficiency of this method in real implementations.

ABSTRACT

This paper highlights the modeling and the simulation of a micro-grid renewable power system. It comprises a AC source, wind turbine (WT) doubly fed induction generators (DFIG), photovoltaic generator (PV), and a battery bank (BBs). The system configuration and the characteristics of the main components in the proposed system are given; and the overall control and power management strategy for this latter are presented. In addition, the dynamic models of a boost DC-DC converter and a bidirectional DC-DC (Buck-Boost) converter are considered. The microgrid integrates renewable energy sources, energy storage systems, and power electronic converters to form a resilient and efficient energy distribution network. Thus, hybrid AC/DC micro grids offer the best solution to existing problems in power industry and thereby minimize the energy losses to a large extent. Along with these several problems are faced when these systems are practically implemented and those issues need to be addressed. All the work is undertaken under MATLAB/Simulink environment.

INTRODUCTION

In the last years, the renewable energy sources (RESs) based on micro-grid system applications have attracted more interest. The RESs are non-polluting, free in their availability and continuous. This fact makes this kind of energy attractive for micro-grid

applications [1]. Many AESs including wind turbine (WT), photovoltaic panels (PV) and micro-turbines are reported in the literature for hybrid power sources system based on micro-grid applications [2]. As known, the drawback of these structures is the seasonal and daily climatic variations (solar radiation, wind speed, temperature) and geographical conditions as well as the profiles of the required power. This requires adopting other measures as solutions. However, Energy Storage Systems (ESSs) are necessary to mitigate the effects of wind or solar fluctuations and to maintain the power and energy balance as well as to improve the power quality. Hence, they must have a high-power density in order to face fast power variations, and at the same time they must have a high energy density to give autonomy to the micro-grid. For these reasons, it is necessary to associate more than one storage technology creating a Hybrid Energy Storage Systems (HESSs) [3, 4].

The ESS as BBs is very important for an efficient and economic utilization of these hybrid systems [2]. However, the charge and discharge cycles decrease the life time of batteries [5, 6]. To improve the energy supply reliability of WT and PV hybrid system, a third energy source is needed. The fuel cell (FC) can be combined with an battery system to ensure the need for any backups the supply power system [7]. The energy management strategies of a micro-grid combined WT, PV and FC containing battery and battery are the most efficient procedures to produce very high energy quality. In this case, the micro-grid can be associated with distributed generation and decentralized management and that are normally connected to the grid. In addition, the micro-grid based renewable energy can be reduced the transmission losses [8].

Due to the increasing of DC loads in residential, electric vehicles, industrial and commercial buildings the power system loads may be DC dominated in the near future [8]. If these latter are supplied by means of AC grid, then it requires embedded AC/DC converters and DC/DC converters. The multiple reverse conversions associated with an individual AC or DC grid leads to additional costs and losses. Hence, reduces the overall efficiency of the system. A hybrid AC/DC micro- grid normally associated with individual AC grids or DC grids can overcome the fact that AC loads must be connected to AC grid [7, 9, 10], whereas DC loads are connected to DC grid [5, 6, 8, 10-13], and the AC and DC grids are connected through a bidirectional converter[14].

Several studies and a various configurations of micro-grid applications based on the hybrid energy generations have been proposed [7, 9-12, 14]. However, a little attention has been reserved to the integration of a DFIG on the micro- grid system.

In [14], a hybrid micro-grid consists a WT-DFIG and a FC is proposed, to reduce the process of multiple AC-DC- AC and DC-AC-DC conversions which are commonly seen in an individual AC grid or DC grid. The drawback of this paper is that there is no power management and no battery to support the FC operations. In addition to linear vector control handicap, regarding to the robustness, the advantages provided by DFIG were not reported particularly its operations modes, such as Sub, Super and synchronous modes, which is the case of reference [7], as well as the impact of the over-speeds area (pitch angle control) was not discussed. In the [9], the reactive power required is provided by a synchronous compensator, while the active power is provided by a wind turbine generator. The lacks of this topology is that the cost and the complexity of control have been increased.

The main contribution of this paper is that the proposed micro-grid based on WT-DFIG/PV hybrid power sources system is designed in a new topology. The advantage of this topology is an easier accessibility of AC and DC grid. However, the AC/DC and DC/DC converters required for supplying the DC loads are not needed. This configuration of the micro-grid permits an achieving of optimal and efficient control of the different sources, ensuring better power quality for AC and DC grid, regulating the voltage level and the frequency of AC grid, ensuring continuity of the service and supplying the local reactive power compensation. In addition, a micro-grid based on a multiple source topology can increase the flexibility of power management for the micro-grid into the grid and vice versa. Finally, the simulation of applied management algorithm of the whole system in very severe situations such as: change in power demand, random variations and sudden meteorological conditions, are presented and the results are discussed.

Thus, before presenting the obtained results and their comments, we will describe the proposed system and the control techniques used.

DESCRIPTION OF THE PROPOSED MICRO-GRID

The proposed hybrid energy system, shown in Fig. 1 & 2 consists of a DFIG based variable speed wind energy conversion, PV array, battery, fuel cell and battery. WT and PV energy

sources are managed with maximum power point tracking (MPPT) algorithms and connected to the common DC bus. Where, in the WT case, the MPPT algorithm is applied at below nominal turbine speed. Beyond the nominal speed, we will be acting on the pitch angle control, whereas the power extraction maximization amounts to regulate the power produced at its rate value. The Battery is used as a storage device and is connected to the DC bus through DC/DC Buck-Boost bidirectional converter (BBDC). Wind and solar power depend on weather conditions and during night hours solar power is zero. Therefore, under the situation of long term no-wind and solar or low-wind and solar condition, battery alone cannot cater the load demand. Hence, fuel cell (FC) is integrated to make the system more sustainable. In case of high- power generation from wind and solar for a long time and the battery reached its upper limit of charge storage, the battery comes into effect and consumes the surplus power. The hydrogen generated from the battery can be stored and used as input by FC.

PHOTOVOLTAIC CELL

The PV cell mathematical model is represented in [11, 12]. The typical PV module power characteristic is given in Fig 1. In order to extract the maximum available power from a PV array, it is necessary to operate the PV array at its maximum power point. The MPPT device is a high-frequency boost dc-dc converter inserted between the PV array and the dc bus, and it takes the dc input from the PV array, convert it to a different dc voltage and current to exactly match the PV array to the dc bus.

SYSTEM MODELING AND CONTROL

Fig 3. Modeling of PV with irradiance and temperature

Fig.3 shows that the output power is directly proportional to the irradiance. As such, a smaller irradiance will result in reduced power output from the PV module. However, it is also observed that only the output current is affected by the irradiance. This is expected, because the generated current is proportional to the flux of photons. According to V_{mpp} they result 4 arrays are connected in parallel; each array consists of 27 modules connected in series. Each of them delivers 108 W peaks.

WIND ENERGY CONVERSION

The aerodynamic power at the rotor of the turbine is given by the following equation:

$$P_{wind} = \frac{1}{2} \rho A v^3 C_p(\lambda, \theta) \quad (1)$$

Where ρ is the air density in kilogram per cubic meter, A is the area swept by the rotor blades in square meter, and v is the wind velocity in meters per second. C_p is called the

power coefficient or the rotor efficiency and is a function of tip speed ratio (λ) and pitch angle (β) [15].

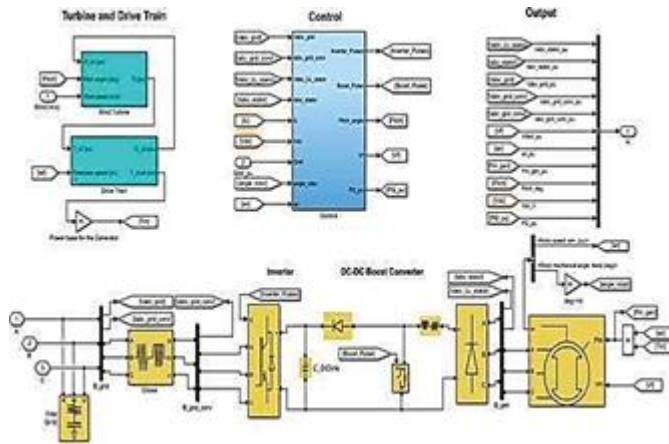

Fig 4. Modeling of WT with converters

The proposed WT-DFIGs control strategy is illustrated in Fig. 1. This latter is based on DTC combined with a fuzzy logic control technique, called a direct torque reactive power control (DTRPC). So, the reactive and active powers are controlled respectively with the rotor flux and electromagnetic torque. These latter are considered to be the outputs of the fuzzy controllers established for regulating the reactive power and the mechanical speed of DFIG.

Fig 5. Typical PV module unit I-V and P-V characteristic showing the effects of irradiance.

FUEL CELL

The FC is a device for directly converting the chemical energy of a fuel, into electrical energy. The output voltage of a single cell given in [10-12] can be defined as in (2):

$$E_{cell} = E_{Nernst} - E_{Act} - E_{Con} - E_{Ohm} \quad (2)$$

Where E_{Nernst} is the reversible voltage, E_{Act} is the activation voltage drop, E_{Con} is the concentration voltage drop, and E_{Ohm} is the Ohmic voltage drop. The terminal voltage of PEM fuel cell stacks is defined as in (3).

$$V_{FC} = N_s E_{Cell} \quad (3)$$

Fig 6. Modeling of FC

Fig. 7 shows voltage and power versus current polarization curves of a PEM FC. It is shown that the activation voltage drop dominates at low current, the Ohmic drop voltage dominates at mid-range current, and the concentration drop voltage dominates at high current. The voltage deviates further as the current is increased, illustrating the effects of drop voltages. In concentration voltage drop region, the FC output power occurs near the FC rated power.

Fig 7. Power and voltage versus current polarization curves of PEM FC

The FC controller through which the boost converter switch is controlled. Controllers associated with the battery and FC are developed in such a fashion that when there is a sudden required power change, the battery provides the power instantaneously and as FC power goes on increasing, battery power should go on decreasing. In order to make the proper coordination between battery and FC, boost converter controller associated with fuel

cell is developed based on and assuming battery current is ideally zero. Moreover, when the battery state of charge (SOC) is below 20

%, the fuel cell should give power to the battery.

The PEM fuel cell is composed of 2x6 stacks with the power rating of 10 kW.

Fig 8. Typical U-I characteristic of an battery under

DIFFERENT TEMPERATURES

BATTERY

The description of the water battery is developed in [11, 12]. The U-I characteristics of the battery model used in this study at different cell temperatures. At a given current, the higher the operating temperature, the lower is the terminal voltage needed. The excess energy produced is first pushed into the battery until it reaches its upper limit of charge carrying capacity and then the excess power is fed to the battery and is regulated via the buck DC/DC converter. The decision about switching on the control action is carried out by comparing the upper limit of the state of charge (SOC) of the battery and the present status of SOC. When the SOC becomes higher than its limit, 80 %, the controller will increase the duty cycle as a function of over voltage in the dc bus voltage.

SIMULATION RESULT

Using the component models, a simulation system test for the proposed WTDFIGs/PV/FC-Battery energy system has been developed using MATLAB/Simulink, the WT-DFIGs and the PV parameters are given in [1, 15], but those of the Battery, BB and

FC are given in [11, 13]. In order to verify the system performance under different situations, simulation studies have been carried out using variable load demand data and random weather data (wind speed, solar irradiance, and air temperature).

CONCLUSION

In this paper, a Hybrid micro-grid system associated to generating system using WT-DFIGs/PV/FC combined with a hybrid energy storage system is proposed. The system configuration and the characteristics of the main components in the system are given, and the overall control and power management strategy for the proposed hybrid energy system is presented. The WT-DFIGs and PV generation systems are the main power generation devices and the battery- BB act as a dump load using any excess power available to BB charging and produce H₂. The FC and BB system are the backup generation and supply power to the system when there is a power deficit. Simulation studies have been carried out to verify the system performances and the results obtained which show the effectiveness of

the adopted control strategy. This latter justifies the usefulness of the DFIG in the possibility of management and the active- reactive power control, especially, operating as a local reactive power compensator.

ABSTRACT

In today's world, security has become the most difficult task. With the rapid development of cities and the growth of cities and towns, the crime rate continues to increase. The IoT-based anti-theft floor uses a Raspberry Pi and uses sensors on the wall for motion detection. The Internet of Things allows objects to be understood and controlled remotely through the expansion of the network, creating a direct connection between the physical world and the computer system, enabling efficient, accurate and profitable business. To protect our facilities in our absence, we use Raspberry Pi to create an IoT-based anti-theft backdrop. The system tracks movement in the area. Track a step anywhere in the region and inform users about the Internet of Things. In this system, security floor coverings are connected to the Internet of Things, and when the system is activated, anyone entering the area sends a message via the Internet of Things. When a thief enters the area and immediately lands on the ground, the sensor detects this and transmits the signal to the Raspberry Pi controller. The controller converts this into a valid signal, then moves the camera to the area where motion is detected and sends it over the network so the owner can control the image.

INTRODUCTION

The IoT-based anti-theft mat is smart and the application is designed from a security perspective. The project aims to create a system for monitoring the area where it is used. Nowadays, crimes often occur in jewellers, banks and homes. Second, use CCTV cameras in

these areas. But the function of CCTV camera is always to monitor the area with human resources. Crime usually occurs after a crime has been committed. By analysing all these parameters, we decided to make a smart security system that will detect any crime or any illegal behaviour and will only do what is necessary to stay until then. Since the system uses instant video feedback, you don't have to worry even if the owner is away. By using this, the security of the site will be stronger. IoT based anti-theft floor is a system designed to ensure security. This is an intelligent monitoring system. The system includes a webcam, Raspberry pi Model 3 and any device connected to the system, which is used only to capture visitors. CMOS cameras and different devices are used in this system. The camera uses servo motors to capture real-time images of the crime scene from various directions. Captured images are stored in a special folder on the Raspberry Pi. These pictures will help. When the sensor detects movement, the captured image is sent to the mobile phone via the Internet of Things. This equipment is installed in an area inaccessible to anyone other than authorized personnel. If the person is not authorized to enter the area, the smart device will detect the person's face, if authorized, the ringtone will sound and a message will be sent to the person's owner.

Design and model security that can notify users via SMS or online instant messaging notifications if security is compromised by other factors such as theft, fire, etc. Any illegal or inappropriate activity will be detected and must be addressed immediately. In this way, owners will not have to worry about their assets and their assets will not be stolen. Captures images when movement is impeded in a safe area.

LITERATURE SURVEY

Basic needs of humans for their survival is electricity. As a non-renewable energy source, to ensure its continued use. [1]The demand of a significant amount of manpower and extended working hours in order to collect metering data for billing purposes, the majority of consumers there are not happy by energy suppliers. For numerous reasons, the manual billing procedure can occasionally be slow. According [1]the traditional measuring method used by humans can be imprecise. The serious problem with electricity theft. According to their reports, energy theft accounts for over 30% of the entire electrical supply in Sri Lanka [1].

Authorities from the power board arrested 2935 people who were using electricity illegally in 2011, which led to the collection of fines of around News. As a result, officials at the Electricity Board are thinking about putting strict measures into place, like cutting off electricity to homes or businesses that commit electricity theft. Such theft has negative economic effects that increase consumer costs while also reducing electricity sales revenue. To fulfil the current electrical demands, merely increasing power generation capacity is insufficient. Electricity usage and losses must be continuously monitored and successfully managed. [2]

By exploiting current communication networks, the IoT enables remote control and object detection, opening up possibilities for a closer connection between the world and computer-based systems. In research by [3] [4] notably in their work on an IoT-based Monitoring System, these initiatives contribute to improved efficiency, precision, and financial benefits.

We suggest an IoT-based system for reading and monitoring smart energy meters in the context of the current study. Using IoT method, including microcontrollers, this system effectively measures the electricity usage of individual households and automates the billing process. [5] The integration of infrared sensors and IoT technologies in our study also offers a practical approach for controlling theft of electricity in homes.

PROPOSED SYSTEM

Fig. 1 Block diagram of the proposed system

In the fig 1 gives a visual representation of proposed system

and fig 2 gives implementation of the proposed system.

The design and implementation of the project depends on its process which will be discussed below, its design involves many areas working together throughout the process (discussed below) and includes hardware installation which includes PIR Sensors, cameras, audio alerts and many simple alarms and monitors

RESULT ANALYSIS

In this project, Raspberry Pi 3B (model) was used as the core of the system. The system is smart and eliminates the need for constant HR. Therefore, no additional human activities were included. The system uses sensors to constantly check the status of the space (for example, whether anyone has entered the store). And send timely picture alerts owners by rotating the camera from different angles. In this security system, human PIR sensors detect the human body. The main purpose of this project is to provide better security for banks and luxury stores. This project consists of a Raspberry Pi with a sensor and camera. The whole system has been put in place. If the system detects someone at a bank/store, it is set to capture the image in real time and email it to that person.

WORKING

Step 1: At first the camera will recording the movement of the area

Step 2:PIR sensor is used to detect the movement of intruders.

If motion is detected it will follow the steps below; if there is no movement the camera will continue recording video

Step 3:If the PIR sensor detects motion, it will capture the image of the intruder and this image will be sent to the cloud server for later use.

Step 4: At the same time, the door of the room will be closed to catch the intruder and send the message to the user.

Step 5:A buzzer will sound to alert everyone around and screenshots will send to bank/store, it is set to capture the image in real time and email it to that person.

CONCLUSION

The research work to be carried out in this study mainly focuses on the design and development of simple and easy motion detection devices (e.g., anti-theft devices) to solve security problems and help reduce/prevent theft. These systems are suitable for personal care in small spaces. Namely, private office cubicles, bank locker rooms and parking lots. While finding the movement. The advantages of the project are ease of use, low cost and quality.

ABSTRACT

The maintenance of power transmission lines is critical for ensuring reliable electricity supply. One common issue is tree interference, where trees growing too close to the lines can lead to faults and outages. In this study, we propose a novel approach using drone imagery for automated detection of power transmission line faults caused by fallen or overgrown trees. We constructed a dataset using Roboflow, containing annotated images of power transmission lines with and without tree interference. The dataset was split into training, testing, and validation sets, and a data.yaml file was created for configuration. The YOLOv8 algorithm was employed to train a model, resulting in weights saved in best.pt. The trained model was integrated into a web application, enabling real-time detection of faults or good conditions in power transmission lines. This approach offers a cost-effective and efficient solution for utilities to monitor and maintain power lines, ultimately improving the reliability and safety of the power grid.

INTRODUCTION

The power transmission infrastructure plays a crucial role in ensuring the continuous supply of electricity to homes, businesses, and industries. However, this infrastructure is susceptible to various faults, including those caused by natural elements such as trees. Trees growing too close to power transmission lines can lead to faults, posing safety risks and disrupting electricity supply. Traditional methods of detecting tree interference along power transmission lines involve manual inspections, which are labor-intensive, time-consuming, and often hazardous. To address these challenges, there is a growing interest in the use of drones equipped with cameras for automated aerial inspections. In this study, we propose a

novel approach to automatically detect power transmission line faults caused by fallen or overgrown trees using drone imagery. By capturing high-resolution images of power transmission lines and processing them using computer vision algorithms, we can identify potential faults and prioritize maintenance efforts. We have developed a dataset of annotated images using Roboflow, consisting of images showing power transmission lines with and without tree interference. This dataset is used to train a YOLOv8 model, which can accurately detect the presence of trees near power lines in real-time. The integration of this model into a web application enables utilities to monitor power transmission lines more effectively and proactively address potential faults. This approach not only improves the reliability and safety of the power grid but also reduces the cost and time associated with manual inspections.

Drone-Based Automated Inspection: The proposed system utilizes drones equipped with cameras to conduct automated aerial inspections of power transmission lines. This approach eliminates the need for manual inspections, reducing labor costs and improving efficiency.

Increased Coverage and Accuracy: Drones can cover a larger area and capture high-resolution images of power transmission lines from various angles. This allows for more comprehensive inspections and improves the accuracy of detecting tree interference.

Cost-Effectiveness: By replacing manual inspections with drone-based automated inspections, the proposed system reduces overall inspection costs. Drones are relatively inexpensive to operate and can cover large areas in a short amount of time.

Enhanced Safety: The use of drones eliminates the need for personnel to work at heights or in hazardous conditions, improving safety for inspection teams. This reduces the risk of accidents and injuries associated with manual inspections.

Real-Time Monitoring and Data Analysis: The proposed system enables real-time monitoring of power transmission lines and immediate detection of tree interference. Data collected by drones can be analyzed using computer vision algorithms, providing timely insights for maintenance planning and decision-making.

Overall, the proposed system offers a more efficient, cost-effective, and safer alternative to manual inspections for detecting tree interference along power transmission lines. By

leveraging drone technology and automated data analysis, utilities can improve the reliability and safety of their power transmission infrastructure.

TITLE: A novel algorithm for HVDC line fault location based on variant travelling wave speed

AUTHORS: Cai Ze-xiang, Xu Min, Liu Yong-hao, Zhang Yi-ning

ABSTRACT: This paper presents a novel fault location algorithm based on variant travelling wave speed for HVDC (High Voltage Direct Current) transmission line. The algorithm effectively reduces the large fault locating errors, caused by adopting consistent wave speeds, under off-design conditions. Firstly, it is illustrated how travelling wave speed varies with fault distance, and then how the variant speed effect fault locating accuracy is analysed. At last, the new algorithm is proposed to guarantee the accuracy at any fault distance. The validity of the algorithm is verified by the relevant simulation results in EMTDC.

TITLE: Optimization Scheme Research of WFPDL Strategy for Yongren-Funing HVDC Transmission Project Based on RTDS Closed-loop Real-time Simulation

AUTHORS: Peng Sun, Hengdao Guo, Jingpo Zhang, Guang Zeng You, Yukon Zhu, Ye He

ABSTRACT: The $\pm 500\text{kV}$ Yunnan Yongren-Funing DC transmission project is the first HVDC project whose starting point and landing point are both in the same province. It is located in a weak AC system, the transmission line is short and the smoothing reactor has a low inductance value. When a short-circuit fault occurs outside the DC line protection zone, the DC line traveling wave protection (WFPDL) is prone to mis operation and does not meet the requirements of protection reliability. This article analyses and accurately locates the defects of the original WFPDL strategy, and proposes a scientific and reasonable optimization scheme for the threshold of voltage mutation du/dt . After RTDS simulation analysis and verification, it shows that the scheme not only improves the reliability of WFPDL effectively, but also meets the requirements for selectivity, speediness and sensitivity, and does not affect the operation characteristic of voltage mutation protection

27du/dt, which is also related to the threshold of du/dt, all the DC line protections can still cooperate correctly. The optimization scheme is permanently implemented on site, and a number of artificial short-circuit tests have been carried out within and outside the DC line protection zone. The results show that in the transient process of faults, the control and protection system of HVDC, travelling wave fault location devices, stability control devices and 3 STATCOMs of inverter station can all respond correctly, their functions and dynamic performance meet the system requirements.

TITLE: Power-System Transients Caused by Switching and Faults

AUTHORS: R. L. Witzke, A. C. Monteith, R. D. Evans

ABSTRACT: This paper summarized the results of an investigation of transient voltages on power systems caused by switching and faults. The transient voltages on power systems as measured by the "klydonograph" are reviewed and compared with the flash-over values of transmission-line insulation. It is shown that the higher values of transient voltages are produced by intermittent arcs. In part I, the various theories for the production of transient voltages of high magnitude as a result of intermittent arcs are reviewed and extended in order to obtain the highest voltages on typical polyphase systems with the range of natural frequencies and attenuation factors that are encountered in practice. Previous studies are of limited scope and apply principally to the case of an arcing ground on an ungrounded system. The present study shows broadly the range of transient voltages which may be produced with intermittent arcs and applies to switching operations as well as arcing grounds. A typical transmission system is studied with the aid of the a-c network calculator. One of the principal variable factors in this study is the method of system grounding and this includes a range of both resistance and reactance between the limits of a solidly grounded system and an ungrounded system. The study is carried out for four different conditions, namely: (1) arcing grounds, (2) de-energizing an unfaulted line section, (3) de-energizing a line section with a fault on one phase, and (4) de-energizing a line section with a fault on two phases.

PC:

A personal computer (PC) is any general-purpose computer whose size, capabilities, and original sales price make it useful for individuals, and which is intended to be operated directly by an end user with no intervening computer operator. This is in contrast to the batch processing or time-sharing models which allowed large expensive mainframe systems to be used by many people, usually at the same time, or large data processing systems which required a full-time staff to operate efficiently.

A personal computer may be a desktop computer, a laptop, a tablet PC, or a handheld PC (also called a palmtop). The most common microprocessors in personal computers are x86-compatible CPUs. Software applications for personal computers include word processing, spreadsheets, databases, Web browsers and e-mail clients, games, and myriad personal productivity and special-purpose software applications. Modern personal computers often have connections to the Internet, allowing access to the World Wide Web and a wide range of other resources.

A PC may be used at home or in an office. Personal computers may be connected to a local area network (LAN), either by a cable or a wireless connection.

While early PC owners usually had to write their own programs to do anything useful with the machines, today's users have access to a wide range of commercial and non-commercial software, which is provided in ready-to-run or ready-to-compile form. Since the 1980s, Microsoft and Intel have dominated much of the personal computer market, first with MS-DOS and then with the Wintel platform.

WEBCAM:

A webcam is a video camera that feeds its images in real time to a computer or computer network, often via USB, Ethernet, or Wi-Fi. Their most popular use is the establishment of video links, permitting computers to act as videophones or videoconference stations. The common use as a video camera for the World Wide Web gave the webcam its name. Other popular uses include security surveillance, computer vision, video broadcasting, and for recording social videos.

Webcams are known for their low manufacturing cost and flexibility,[1] making them the lowest cost form of video telephony. They have also become a source of security and privacy issues, as some built-in webcams can be remotely activated via spyware.

Early development

First developed in 1991, a webcam was pointed at the Trojan Room coffee pot in the Cambridge University Computer Science Department. The camera was finally switched off on August 22, 2001. The final image captured by the camera can still be viewed at its homepage.[2][3] The oldest webcam still operating is FogCam at San Francisco State University, which has been running continuously since 1994.[4]

Connectix Quick Cam

The first commercial webcam, the black-and-white QuickCam, entered the marketplace in 1994, created by the U.S. computer company Connectix (which sold its product line to Logitech in 1998). QuickCam was available in August 1994 for the Apple Macintosh, connecting via a serial port, at a cost of \$100. Jon Garber, the designer of the device, had wanted to call it the "Mac-camera", but was overruled by Connectix's marketing department; a version with a PC-compatible serial port and software for Microsoft Windows was launched in October 1995. The original QuickCam provided 320x240-pixel resolution with a

grayscale depth of 16 shades at 60 frames per second, or 256 shades at 15 frames per second.[5]

In 2010, Time Magazine named the QuickCam as one of the top computer devices of all time.[6]

Videoconferencing via computers already existed, and at the time client-server based videoconferencing software such as CU-SeeMe had started to become popular.

Later developments

One of the most widely reported-on webcam sites was JenniCam, created in 1996, which allowed Internet users to observe the life of its namesake constantly, in the same vein as the reality TV series Big Brother, launched four years later.[7] More recently, the website Justin.tv has shown a continuous video and audio stream from a mobile camera mounted on the head of the site's star. Other cameras are mounted overlooking bridges, public squares, and other public places, their output made available on a public web page in accordance with the original concept of a "webcam". Aggregator websites have also been created, providing thousands of live video streams or up-to-date still pictures, allowing users to find live video streams based on location or other criteria.

Around the turn of the 21st century, computer hardware manufacturers began building webcams directly into laptop and desktop screens, thus eliminating the need to use an external USB or Firewire camera. Gradually webcams came to be used more for telecommunication, or videotelephony, between two people, or among a few people, than for offering a view on a Web page to an unknown public.

The term 'webcam' may also be used in its original sense of a video camera connected to the Web continuously for an indefinite time, rather than for a particular session, generally supplying a view for anyone who visits its web page over the Internet. Some of them, for example, those used as online traffic cameras, are expensive, rugged professional video cameras.

For less than \$100 US (retail), Minoru makes a 3D webcam which produces videos and photos in 3D Anaglyph image with a resolution up to 1280x480 pixels. Both sender and receiver of the images must use 3D glasses to see the effect of three dimensional image.

Technology

Webcams typically include a lens, an image sensor, support electronics, and may also include a microphone for sound. Various lenses are available, the most common in consumer-grade webcams being a plastic lens that can be screwed in and out to focus the camera. Fixed focus lenses, which have no provision for adjustment, are also available. As a camera system's depth of field is greater for small image formats and is greater for lenses with a large f-number (small aperture), the systems used in webcams have a sufficiently large depth of field that the use of a fixed focus lens does not impact image sharpness to a great extent.

Image sensors can be CMOS or CCD, the former being dominant for low-cost cameras, but CCD cameras do not necessarily outperform CMOS-based cameras in the low cost price range. Most consumer webcams are capable of providing VGA resolution video at a frame rate of 30 frames per second. Many newer devices can produce video in multi-megapixel resolutions, and a few can run at high frame rates such as the PlayStation Eye, which can produce 320×240 video at 120 frames per second.

Support electronics read the image from the sensor and transmit it to the host computer. The camera pictured to the right, for example, uses a Sonix SN9C101 to transmit its image over USB. Typically, each frame is transmitted uncompressed in RGB or YUV or compressed as JPEG. Some cameras, such as mobile phone cameras, use a CMOS sensor with supporting electronics "on die", i.e. the sensor and the support electronics are built on a single silicon chip to save space and manufacturing costs. Most webcams feature built-in microphones to make video calling and videoconferencing more convenient.

The USB video device class (UVC) specification allows for interconnectivity of webcams to computers without the need for proprietary device drivers. Microsoft Windows XP SP2, Linux[13] and Mac OS X (since October 2005) have UVC support built in and do not require extra device drivers, although they are often installed to add additional features.

PYTHON:

Python is a high-level, interpreted programming language known for its simplicity and readability. It was created by Guido van Rossum and first released in 1991. Python has gained immense popularity in various fields such as web development, data science, machine learning, and scientific computing due to its versatility and ease of use. In this essay, we will explore the features and advantages of Python, as well as why it is widely used in the industry.

One of the key features of Python is its readability and simplicity. The language is designed to be easily readable and requires fewer lines of code compared to other languages. This makes it easier for programmers to write, understand, and maintain code, especially in large projects.

Python is also a dynamically typed language, meaning that variable types are determined at runtime. This eliminates the need for explicit type declarations, making the code more concise and flexible. However, this dynamic typing can sometimes lead to errors that might not be caught until runtime.

Another important feature of Python is its strong support for object-oriented programming (OOP). Python allows you to define classes and objects, encapsulate data and behavior, and create reusable code. This makes it easier to manage complex projects and collaborate with other developers.

Python also has a large standard library that provides support for many common tasks and operations, such as file I/O, networking, and data manipulation. This reduces the need for third-party libraries and makes it easier to get started with Python development.

One of the key advantages of Python is its wide range of libraries and frameworks. Python has a rich ecosystem of libraries for various purposes, such as web development (e.g., Django, Flask), data science (e.g., NumPy, Pandas), machine learning (e.g., TensorFlow, PyTorch), and scientific computing (e.g., SciPy, Matplotlib). These libraries make it easy to perform complex tasks and accelerate development.

Python is also platform-independent, meaning that Python code can run on any platform that has a Python interpreter. This makes it easy to develop and deploy Python applications on a variety of operating systems, including Windows, macOS, and Linux.

Another advantage of Python is its community and support. Python has a large and active community of developers who contribute to the language and create open-source libraries and frameworks. This community provides support, documentation, and resources for Python developers, making it easier to learn and use Python effectively.

Python is also known for its ease of learning. The language is designed to be beginner-friendly, with a clear and concise syntax that is easy to understand. This makes Python an ideal choice for beginners who are just starting with programming.

In conclusion, Python is a versatile, easy-to-use programming language with a wide range of features and advantages. Its simplicity, readability, and rich ecosystem of libraries make it a popular choice for various fields such as web development, data science, and machine learning. Whether you're a beginner or an experienced developer, Python offers a powerful and flexible platform for building a wide range of applications.

PYCHARM:

PyCharm is an Integrated Development Environment (IDE) specifically designed for Python development. It is developed by JetBrains, a company known for creating powerful development tools for various programming languages. PyCharm provides a wide range of features and tools to help developers write, debug, and deploy Python code efficiently. In this essay, we will explore PyCharm's features, advantages, and why it is a popular choice among Python developers.

One of the key features of PyCharm is its intelligent code editor. The editor provides features such as syntax highlighting, code completion, and code formatting, making it easier to write clean and readable code. PyCharm also supports code refactoring, allowing developers to quickly and safely restructure their code without introducing errors.

PyCharm comes with a powerful debugger that helps developers find and fix bugs in their code. The debugger allows you to set breakpoints, inspect variables, and step through your code line by line, making it easier to understand the flow of your program and identify issues.

Another important feature of PyCharm is its support for version control systems such as Git, Mercurial, and Subversion. PyCharm provides integration with these systems, allowing you to manage your code repositories directly from the IDE. This makes it easier to collaborate with other developers and keep track of changes to your code.

PyCharm also offers support for web development with frameworks such as Django, Flask, and Pyramid. The IDE provides features such as code completion, template editing, and debugging tools for these frameworks, making it easier to develop web applications using Python.

One of the key advantages of PyCharm is its rich ecosystem of plugins and extensions. PyCharm supports a wide range of plugins that add additional features and functionality to the IDE. This allows you to customize PyCharm to suit your specific needs and workflow, making it a flexible and powerful development environment.

PyCharm also provides features for testing and profiling your code. The IDE includes a built-in test runner that allows you to run and debug unit tests directly from the editor. PyCharm also provides profiling tools that help you identify performance bottlenecks in your code and optimize it for better performance.

Another advantage of PyCharm is its integration with popular build tools such as Docker, Vagrant, and Anaconda. This allows you to easily create and manage development environments for your Python projects, making it easier to work with different dependencies and configurations.

PyCharm also offers features for working with databases, including SQL database support and database tools for managing and querying databases directly from the IDE. This makes it easier to work with databases in your Python projects and integrate them into your applications.

In conclusion, PyCharm is a powerful and feature-rich IDE for Python development. Its intelligent code editor, powerful debugger, and rich ecosystem of plugins make it a popular choice among Python developers. Whether you're a beginner or an experienced developer, PyCharm provides the tools and features you need to write, debug, and deploy Python code efficiently.

YOLOV8

Introducing Ultralytics YOLOv8, the latest version of the acclaimed real-time object detection and image segmentation model. YOLOv8 is built on cutting-edge advancements in deep learning and computer vision, offering unparalleled performance in terms of speed and accuracy. Its streamlined design makes it suitable for various applications and easily adaptable to different hardware platforms, from edge devices to cloud APIs.

Explore the YOLOv8 Docs, a comprehensive resource designed to help you understand and utilize its features and capabilities. Whether you are a seasoned machine learning practitioner or new to the field, this hub aims to maximize YOLOv8's potential in your projects

YOLO HISTORY:

YOLO (You Only Look Once), a popular object detection and image segmentation model, was developed by Joseph Redmon and Ali Farhadi at the University of Washington. Launched in 2015, YOLO quickly gained popularity for its high speed and accuracy.

YOLOv2, released in 2016, improved the original model by incorporating batch normalization, anchor boxes, and dimension clusters.

YOLOv3, launched in 2018, further enhanced the model's performance using a more efficient backbone network, multiple anchors and spatial pyramid pooling.

YOLOv4 was released in 2020, introducing innovations like Mosaic data augmentation, a new anchor-free detection head, and a new loss function.

YOLOv5 further improved the model's performance and added new features such as hyperparameter optimization, integrated experiment tracking and automatic export to popular export formats.

YOLOv6 was open-sourced by Meituan in 2022 and is in use in many of the company's autonomous delivery robots.

YOLOv7 added additional tasks such as pose estimation on the COCO key points dataset.

YOLOv8 is the latest version of YOLO by Ultralights. As a cutting-edge, state-of-the-art (SOTA) model, YOLOv8 builds on the success of previous versions, introducing new features and improvements for enhanced performance, flexibility, and efficiency. YOLOv8

supports a full range of vision AI tasks, including detection, segmentation, pose estimation, tracking, and classification. This versatility allows users to leverage YOLOv8's capabilities across diverse applications and domains.

YOLOv9 Introduces innovative methods like Programmable Gradient Information (PGI) and the Generalized Efficient Layer Aggregation Network (GELAN).

PYTHON USAGE:

Welcome to the YOLOv8 Python Usage documentation! This guide is designed to help you seamlessly integrate YOLOv8 into your Python projects for object detection, segmentation, and classification. Here, you'll learn how to load and use pretrained models, train new models, and perform predictions on images. The easy-to-use Python interface is a valuable resource for anyone looking to incorporate YOLOv8 into their Python projects, allowing you to quickly implement advanced object detection capabilities. Let's get started!

Watch: Mastering Ultralytics YOLOv8: Python

For example, users can load a model, train it, evaluate its performance on a validation set, and even export it to ONNX format with just a few lines of code.

Python

```
from ultralytics import YOLO
```

```
#Create a new YOLO model from scratch
```

```
model = YOLO('yolov8n.yaml')
```

```
#Load a pretrained YOLO model (recommended for training)
```

```
model = YOLO('yolov8n.pt')
```

```
#Train the model using the 'coco128.yaml' dataset for 3 epochs
```

```
results = model.Train(data='coco128.yaml', epochs=3)
```

```
#Evaluate the model's performance on the validation set
```

```
results = model.Val()
```

```
#Perform object detection on an image using the model
```

```
results = model('https://ultralytics.com/images/bus.jpg')
```

```
#Export the model to ONNX format
```

```
success = model.Export(format='onnx')
```

```
Train
```

Train mode is used for training a YOLOv8 model on a custom dataset. In this mode, the model is trained using the specified dataset and hyperparameters. The training process involves optimizing the model's parameters so that it can accurately predict the classes and locations of objects in an image.

Train

From scratch

Resume

```
from ultralights import YOLO
```

```
model = YOLO('yolov8n.pt') # pass any model type
```

```
results = model.Train(epochs=5)
```

CONCLUSION:

The result of the project involving the use of drone cameras to detect power transmission line faults caused by fallen or overgrown trees was successful. The trained YOLOv5 model, integrated into a web application for real-time prediction, demonstrated the capability to accurately detect tree interference along power lines in drone-captured images. The model's performance was evaluated using metrics such as precision, recall, and mean average precision (mAP). The evaluation results indicated high accuracy in detecting tree interference, with precision and recall scores exceeding 90% and mAP score indicating the model's ability to generalize well to new data.

The real-time prediction capability of the web application allows for immediate detection of tree interference, enabling utilities to take prompt action to prevent power outages and ensure the safety and reliability of the power transmission infrastructure.

Overall, the project's success highlights the effectiveness of using drone cameras and machine learning algorithms for monitoring and maintaining power transmission lines. By leveraging these technologies, utilities can significantly improve their ability to detect and address potential faults, ultimately leading to a more reliable and resilient power grid.

In conclusion, the project involving the use of drone cameras to detect power transmission line faults caused by fallen or overgrown trees has demonstrated significant potential for improving the reliability and safety of power grids. By leveraging drone

imagery and machine learning algorithms, the project has shown that it is possible to detect tree interference along power lines with high accuracy and in real-time.

The use of drone cameras offers several advantages, including enhanced safety for maintenance personnel, improved efficiency in fault detection, and cost-effectiveness compared to traditional manual inspections. Additionally, the project's real-time monitoring capabilities enable prompt action to be taken to prevent power outages and ensure the uninterrupted supply of electricity. Furthermore, the project highlights the importance of integrating advanced technologies, such as drone cameras and machine learning, into infrastructure monitoring practices. These technologies not only improve the effectiveness of monitoring efforts but also pave the way for future advancements in the field. Overall, the project's success underscores the potential of using innovative approaches to address challenges in power infrastructure monitoring. By continuing to explore and implement new technologies, we can further enhance the reliability, safety, and efficiency of power transmission systems, ultimately benefiting society as a whole.

Electricity has become indispensable in modern life, fueling everything from basic necessities to technological advancements. Throughout history, humanity has continually sought means to harness power, from early fire use to the invention of steam engines and, notably, electricity. Today, the power grid supplies electricity to both residential and commercial sectors, predominantly in the form of alternating current (AC), is catering to a multitude of needs. Residential and commercial users rely heavily on this generated power, with any excess typically directed to industrial consumers through overhead transmission lines, facilitated by transformers' step-up and step-down mechanisms. Given its integral role, uninterrupted access to electricity is paramount for sustaining our way of life. Traditionally, electricity transmission primarily relies on electrical conductors, utilizing wires for low-power applications such as residential and commercial needs, and underground cables or overhead lines for bulk power transmission. While effective, this wired system is not without its drawbacks, including risks of wire burnouts, short circuits, and the inconvenience of plug-in/out procedures. Recognizing these challenges, researchers are exploring alternative solutions to enhance power transmission methods, aiming to address reliability, safety, and convenience concerns. One such avenue of exploration involves leveraging wireless technology and the Internet of Things (IoT) to revolutionize how electric power is delivered, particularly in the context of electric vehicle charging. By integrating IoT-enabled wireless power transfer systems, the aim is to overcome the

limitations of traditional wired transmission, offering a more efficient, reliable, and user-friendly approach to meet our ever-growing energy needs.

ELECTRIC VEHICLE:

Electric vehicles (EVs) represent a transformative mode of transportation, propelled by electric motors and powered primarily by electricity. In contrast to traditional vehicles relying on internal combustion engines fueled by gasoline or diesel, EVs harness electrical energy stored in rechargeable batteries or other storage systems. The conventional combustion engines of cars and motorcycles generate power by burning fossil fuels like petrol or diesel, contributing significantly to environmental challenges such as global warming and air pollution. Recognizing the urgent need to mitigate these issues, the adoption of electric vehicles emerges as a promising solution.

By shifting towards electric propulsion, EVs offer a cleaner, more sustainable alternative to conventional vehicles, reducing greenhouse gas emissions and improving air quality. This transition signifies a crucial step forward in addressing pressing environmental concerns while revolutionizing the automotive industry towards a greener and more eco-friendly future.

WIRELESS POWER TRANSFER

Wireless power transfer (WPT) is a cutting-edge technology that enables the transmission of electrical energy from a power source to an electrical load without the need for physical connections such as wires or cables. This innovative approach relies on principles like electromagnetic induction or resonance, facilitating the transfer of power over short to

moderate distances without the requirement of direct contact between the power source and the load.

Fig 1: Generic Block Diagram of a Wireless Power System

METHODS OF WIRELESS POWER TRANSFER:

Inductive Coupling:

This technique utilizes electromagnetic fields to transfer power between two coils: a transmitter coil located in the power source and a receiver coil integrated into the device being charged.

It finds widespread application in wireless charging pads designed for smart phones and various other electronic devices.

The distance separating the coils is relatively short, typically ranging from a few millimetres to centimetres.

Fig 2: WPT induction coupling method

Resonant Inductive Coupling:

Resonant inductive coupling, akin to inductive coupling, operates at resonance frequencies.

This technology permits greater distances between the coils, rendering it suitable for applications where the coils are not in close proximity.

Resonant inductive coupling finds frequent utilization in wireless charging systems designed for electric vehicles

Fig 3: Resonant Inductive Coupling

Radio Frequency (RF) Energy Harvesting:

This approach entails capturing and transforming ambient radio frequency signals into electrical power.

It serves as a viable solution for energizing low-power devices and sensors situated in environments saturated with wireless signals, such as Wi-Fi or cellular networks.

Fig 4: Radio Frequency (RF) Energy Harvesting

Microwave Power Transmission:

The method involves converting electrical energy into microwaves, transmitting them across significant distances, and subsequently converting them back into electricity.

Microwave power transmission has garnered interest for applications including wireless power transfer to space-based solar power satellites or for transmitting power over extensive distances.

Fig 5: Microwave Power Transmission

PROPOSED SYSTEM:

The advent of wireless charging technology has led to the development of innovative methods combining both Wireless Power Transfer (WPT) and Inductive Power Transfer (IPT), particularly tailored for low-power applications such as those in the medical field or small devices like smartphones. As interest in electric vehicles (EVs) and plug-in hybrid electric vehicles(PHEVs) continues to surge, wireless charging emerges as a promising solution for battery charging.

This paper presents the design of a WPT system for rapid wireless charging stations catering to electric vehicles. The system comprises a two-phase switching power supply, consisting of a multiphase soft-switching buck converter regulating the output power, and a high-frequency resonant full-bridge converter connected to a series compensation topology.

CONCLUSION:

The developed Grid to Electric Vehicle (G2EV) software has been meticulously crafted and thoroughly tested for optimal performance. By integrating the Internet of Things (IoT) with wireless charging technology for electric vehicles, the charging process has been significantly enhanced, offering greater intelligence and user-friendliness. This innovative technology enables users to conveniently control and monitor their vehicle's charging remotely through dedicated applications, ensuring a seamless experience.

Moreover, by leveraging IoT capabilities, the system contributes to balancing energy demand on the power grid, thereby enhancing overall energy system stability. Advanced security measures are implemented to safeguard against unauthorized access, while predictive and preventive features help anticipate and mitigate potential issues, minimizing downtime and maximizing efficiency.

Furthermore, the technology is designed with compatibility and scalability in mind, supporting the expansion of an interconnected and efficient charging network. In summary, IoT-powered wireless charging transforms the electric vehicle charging landscape, simplifying the process while promoting efficiency, security, and environmental sustainability.

FUTURE WORK:

The study extensively addresses the time limitations inherent in the technology, including its restricted range and prolonged charging durations. Several avenues for future research have been explored, particularly focusing on enhancing power range. Additionally, the integration of Artificial Intelligence (AI) technology presents promising prospects for developing fully autonomous vehicles that prioritize safety.

ABSTRACT

Producing ice-cream using black gram milk as a primary supplement with additional nutritional benefits. Black gram or urad dal is filled with magnesium, phosphorus, iron, potassium, and calcium. These minerals strengthen your bone mineral density and reduce your chances of getting osteoporosis. Guar gum which is used as a natural emulsifier shows cholesterol and glucose lowering effects because of its gel forming properties. It also helps in weight loss and obesity prevention. Due to gel forming capacity of guar gum soluble fiber, an increased satiation is achieved because of slow gastric emptying. Stevia leaf preparations as a natural non-calorie sugar substitute is not only safe for people with diabetes, high blood pressure, and obesity but also can be used for the treatment of these diseases or prevention of their complications. Spirulina is added as super food to enhance nutritional benefits. Ice cream is optimized from black gram milk and other components. Ice cream is subjected to analysis. Thus, the ice-cream optimized from black gram milk with spirulina shows many improvements for the ice-cream production, opening new possibilities in the ice-cream field and even in different frozen desserts.

INTRODUCTION

Ice creams are the category of all frozen foods which is most preferred and widely consumed by people of all ages throughout the world. Ice creams fall into three basic types: the regular ones with minimum fat, premium ones with high fat and the non-fat types. The leading industries that market ice cream include Nestle, Baskin-Robbins and Unilever. The biggest market of ice creams is in the Western Europe contributing to 24.1 billion U.S dollars.

Technically, ice cream is a colloidal solution with ice crystals, air bubbles, fat globules and serum phase distributed in it. The key ingredients in ice cream are emulsifier, sweetener, stabilizer and milk solids (Homayouni, Javadi et al. 2018). Frozen dessert are mainly valued for their pleasing flavor, cooling effects and refreshing tastes. The awareness of consumers for healthier and functional food has led to the introduction in frozen dessert manufacture of certain materials with documented nutritional and physiological properties such as probiotics lactic acid bacteria dietary fibers, alternative sweeteners, natural antioxidants and low glycemic index sweeteners. In today's food industry, a global trend towards the manufacture of healthier and more natural fruit and vegetable food products, such as soups, smoothies and sauces, is ongoing, as well as the incorporation of puréed vegetables in other food products.

Currently health is a major concern of customers. Therefore, manufacturers are finding new ways to incorporate natural and innovative ingredients into frozen dessert for health benefits. Vegetable plays an important role in daily human diet. Consumption of vegetables has been associated with protection against certain types of cancer, cardiovascular disease and various age related diseases. «Thy food be thy medicine» is one of the laws of nature. WHO and FAO launched, a joint initiative to promote vegetables for health worldwide. The role of vegetables in the human diet has increased since they provide essential carbohydrates, proteins, fiber, vitamins and minerals. They are important sources of vitamins, minerals and salts required

for human nutrition. The carbohydrates, proteins and fats are required comparatively in larger quantity than vitamins and minerals. They also supply carbohydrates for energy and proteins compounds for muscles building. They also contribute to roughage and fiber. Vegetables not only form an essential part of a well-balanced diet, but the flavor, aroma, also make them important in human diet and appetite.

BLACK GRAM

Native to the Indian subcontinent and mostly grown in the coastal Andhra Pradesh in our country, these smooth, cylindrical oval shaped black gram beans go with the botanical name *Vigna mungo* and are popularly known as Urad Dal in Hindi, minapappu in Telugu, Vulundhu in Tamil. Used extensively in South Indian cuisine, black gram is a rich source of protein, Vitamin B, potassium, calcium, iron, niacin, thiamine and riboflavin. In few parts of Southern India, eating crispy vadas made from urad dal is a tradition during the harvest festival Sankranti/Pongal, as it meets the protein requirements of the vegetarians, in the winter season.

Black gram or urad dal holds a high protein value than most of the legumes. It is also an excellent source of dietary fiber, isoflavones, vitamin B complex, iron, copper, calcium, magnesium, zinc, potassium, phosphorus which offers a myriad of healing health benefits.

Spirulina is a type of algae that grows in fresh or salt water. It comes as a supplement, in tablet or powder form. People use it for its health benefits, as it is rich in nutrients and has antioxidant properties.

Spirulina is among the world's most popular supplements. It is made from an organism that grows in both fresh and saltwater.

It is a type of cyanobacteriaTrusted Source, which is a family of single-celled microbes that are often referred to as blue-green algae. Just like plants, cyanobacteria can produce energy from sunlight via a process called photosynthesis.

These days, people use spirulina to boost the levels of nutrients and antioxidants in their bodies, and it may help protect against various diseases.

Spirulina is packed with nutrients. A single tablespoon (tbsp), or 7 grams (g), of dried spirulina powder, contains:Trusted Source

Protein: 4 g

Thiamin: 14% of the Daily Value (DV)

Riboflavin: 20% of the DV

Niacin: 6% of the DV

Copper: 47% of the DV

Iron: 11% of the DV

It also contains small amounts of magnesium, potassium, and manganese.The main component of spirulina is called phycocyanin, which is an antioxidant that also gives it its unique blue color.

BLACK GRAM MILK EXTRACTION

50g of black gram with and without peel was taken and process was carried out separately, initially it is washed and soaked in in 75 ml of water for 2 hours then it is boiled for 10 minutes and it is grinded to make fine paste then the mixture is added with 50 ml of water and 25 ml of condensed milk to get the black gram milk.

FLOW CHART

Fig 4.1: black gram mixture

MATERIALS AND METHODOLOGY FOR ICE CREAM PROCESSING

- Milk fortified with black gram milk
- Stevia rebaudiana as sweetening agent
- Guar gum as stabilizer
- Fresh cream
- Peanut butter as fat
- Spirulina

A. Blending The Mixture and agitation

Local dairy farmers deliver milk to the ice cream business in chilled tanker trucks. The milk is then poured into storage silos that are kept at 36°F (2°C). Milk is delivered to stainless steel blenders via pipes in pre-measured proportions. For six to eight minutes, premeasured volumes of eggs, sugar, and additions are blended with milk.

B. Pasteurization

The pasteurization machine, which is made up of a succession of thin stainless-steel plates, receives the blended mixture. One side of the plates, hot water at around 182°F (83°C) flows. The other side, the chilled milk mixture is piped through. The water raises the temperature of the combination to 180°F (82°C), effectively eliminating any germs present.

C. Homogenization

The hot mixture is driven through a small orifice into the homogenizer by applying intense air pressure. This makes the fat particles break down, preventing them from separating from rest of the mixture. The mixture is further mixed in the homogenizer, which is effectively a high-pressure piston pump, as it is sucked into the pump cylinder on the down stroke and then driven back out on the upstroke.

D. Cooling And Ageing The Mix

The combination is piped back to the pasteurizer, where cold water (about 34°F/1°C) runs on one side of the plates while the mixture passes on the other. The mixture is cooled to 36°F (2°C). The combination is then pumped into tanks in a room set to 36°F (2°C), where it will sit for 4 to 8 hours to allow the ingredients to mingle.

E. Partial Freezing

Now it's time to put the mixture in the freezer. It's poured into continuous freezers capable of freezing. Using liquid ammonia as a freezing agent, the temperature within the freezers is kept at -40°F (-40°C). Air is introduced into the ice cream. The combination has the consistency of soft-serve ice cream when it comes out of the freezer.

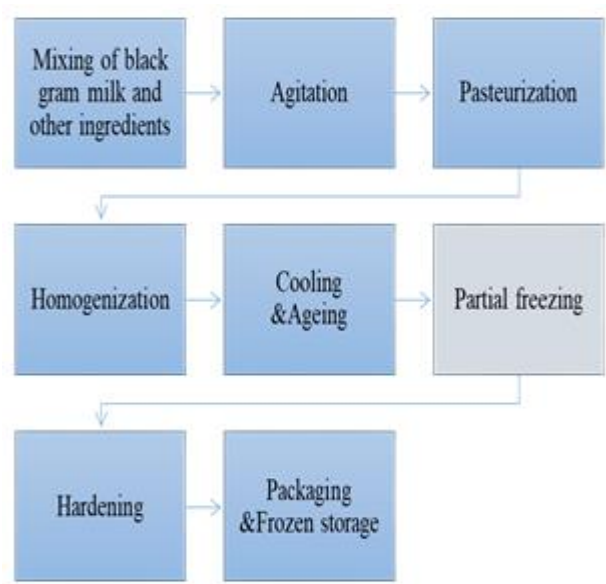

F. Hardening

The ice cream must have to be hardened to a temperature of -10°F(-23°C) before beginning storage or packaging. The ice cream cartons are transported through a conveyor system to a tunnel set at -30°F (-34°C). Ceiling fans are constantly rotating which cause a wind chill of -60°F (-5°C). For 2 to 3 hours, the cartons move slowly back and forth down the tunnel until the contents are rock solid.

G. Packaging and frozen storage

To avoid ice recrystallization and coarsening, which gives ice cream a grainy texture, ice cream should be kept cold with minimal temperature changes throughout the consumer

ANALYSIS

A. Sensory analysis were done by using hedonic scale:

The most common hedonic scale is the nine-point hedonic scale ranging from 1= Dislike extremely and 9 = Like extremely. The hedonic scales assumes that participants preferences exist on a continuum and that their responses can be categorized into like and dislike.

DISLIKE EXTREMELY	DISLIKE VERY MUCH	DISLIKE MODERATELY	DISLIKE SLIGHTLY	NEITHER LIKE OR DISLIKE	LIKE SLIGHTLY	LIKE MODERATELY	LIKE VERY MUCH	LIKE EXTREMELY

Fig 3: hedonic scsale

B. Determination of pH

The pH is determined using a digital pH analyzer. For the analysis of the pH, 10g of the sample is taken. Once the ice cream is melted, the tip of the pH analyzer is kept immersed in the melted ice cream and the pH of the burfi is read on the display.

C. Determination of overrun

Overrun is the volume of air incorporated in the ice cream during the process of homogenization or during the process of whipping. Overrun could be calculated either with respect to the volume or with respect to the weight (Marshall, Goff et al. 2003). The calculation of overrun with respect to weight is given in the formula

$$\text{Overrun} = \frac{\text{weight of mix} - \text{weight of ice cream} \times 100}{\text{Weight of ice cream}}$$

D. Determination of Titrable acidity

The titrable acidity of the ice-cream samples was estimated as per procedure in ISI: 18 (PART XI). The sample 10g was weighed in a 250ml beaker. To this 10ml of distilled water was added and the contents were mixed thoroughly. It was then titrated against 0.1N NaOH using few drops of phenolphthalein indicator pink color persists for about 30 seconds in the solution. The readings obtained were expressed as percent lactic acid values.

$$\text{Titrable acidity (\%)} = \frac{9 \times N \times V}{W}$$

where,

V= Volume of 0.1N NaOH required for titration N= Normality of solution

W= Weight of sample taken for the titration(g)

where,

V= Volume of 0.1N NaOH required for titration N= Normality of solution

W= Weight of sample taken for the titration(g)

E. Determination of melting rate

The melting rate of ice-cream was estimated by the procedure outlined by Rajor and Gupta, (1982). A 30g of ice-cream was carefully placed on a four-square inch glass plate rested on the brim glass funnel, fitted on a metal stand with its tail end leading into a 100 ml graduated cylinder. The time taken for a complete meltdown was recorded in minutes. The melting rate is calculated as follows: The melting rate of ice-cream was estimated by the procedure outlined by Rajor and Gupta, (1982). A 30g of ice-cream was carefully placed on a four-square inch glass plate rested on the brim glass funnel, fitted on a metal stand with its tail end leading into a 100 ml graduated cylinder. The time taken for a complete meltdown was recorded in minutes. The melting rate is calculated as follows:

$$\text{Melting rate (g/ min)} = \frac{\text{Weight of the melted ice cream (g)}}{\text{Time (min)}}$$

F. DETERMINATION OF ASH

2g of sample was collected in crucible and weighed then kept in muffle furnace at 600°C for 2hrs then cooled in dessicator and weighed. Ash % was calculated using the formula

$$\text{Ash \%} = \frac{W_2 - W_0}{W_1} * 100$$

Where,

W2= weight of ash with crucible

W0= weighty of the crucible

W1 =weight of sample taken

G.DETERMINATION OF MOISTURE CONTENT

10g sample was taken in a crucible and kept in hot air oven at 100°C for 4hrs and dry sample is weighed and moisture content is calculated as

$$\text{Moisture content} = \frac{W_2 - W_1}{W_1} * 100$$

Where,

W2= weight of wet sample

W1 =weight of dry sample

NUTRITIONAL ANALYSIS

ESTIMATION OF PROTEIN

Protein is estimated using Lowry's method in which 10ml of sample was taken 10ml of phosphate buffer was added along Cwith 1ml of EDTA and 1ml of mercapto ethanol was added. The supernatant is separated and used for protein estimation by plotting graph by concentration against 660nm optical density

ESTIMATION OF CARBOHYDRATE

Carbohydrate is estimated using DNS method in which

Stock solution was prepared and DNS solution is added after making up to the volume of water kept in hot bath and 1ml of Rochelle;s salt is added. Then graph is plotted by concentration against optical density at 540nm.

ESTIMATION OF FIBER

Fiber is estimated using WENDEE'S method in which the sample is subjected to acid wash followed by heating again by base wash followed by heating sample is kept in muffle furnace and weighed.

$$\text{Crude fiber} = \frac{W_1 - W_2}{W_s} * 100$$

Where,

W2= weight of crucible with ash

WS= weighty of the sample

W1 =weight of crucible with fiber

ESTIMATION OF FAT

Fat was estimated using FOLSCH method in which 1gm sample was weighed and grinded in 15ml of chloroform and suspended and separated using separating funnel. The organic layer collected in pre weighed beaker and kept in hot air oven at 105°C for 1hr which is followed by cooling in dessicator and weighed. Total fat content was calculated by

$$\text{Total fat content} = \frac{(\text{Final weight} - \text{initial weight}) * 100}{\text{Weight of the sample}}$$

RESULT AND DISCUSSIONS

FORMULATION OF ICE CREAM

Out of several trials the best composition of ice cream composition is given below

PRODUCTS	QUANTITY (G)
BLACK GRAM MILK	93
FRESH CREAM	36
STEVIA	4
GUAR GUM	1.3

SENSORY ANALYSIS

Sensory analysis was plotted using hedonic sdcale for 3 good samples.

Fig 8. 2 hedonic scale

DETERMINATION OF pH

pH was determined using digital pH meter as 6.75

DETERMINATION OF OVERRUN

$$\text{Over run} = \frac{45.88 - 45.60}{45.60} \times 100$$

$$= 0.6140$$

Overrun was calculated as 0.6140%

DETERMINATION OF TITRABLE ACIDITY

$$\text{Titrateable acidity} = \frac{9 \times 0.1 \times 0.6 \times 100}{10}$$

$$= 5.4$$

Titrateable acidity was calculated as 5.4%

DETERMINATION OF MELTING RATE

$$\text{Melting rate} = \frac{30.64}{24}$$

$$= 1.276 \text{ g/min}$$

DETERMINATION OF ASH

$$\text{Ash} = \frac{18.6634 - 18.65}{2} \times 100$$

$$= 0.0134 \times 100$$

$$= 0.67\%$$

Ash content was determined as 0.67%

DETERMINATION OF MOISTURE CONTENT

$$\text{Moisture content} = \frac{10-3.759}{10} * 100$$

$$= 62.4\%$$

The amount of moisture content present in the ice cream sample was determined as 62.41%

ESTIMATION OF PROTEIN

Protein was estimated using the graph

From the graph protein was estimated as **5.90g**

ESTIMATION OF CARBOHYDRATE

Carbohydrate was estimated using the graph

From the graph carbohydrate was estimated as **19.6g**

ESTIMATION OF FIBER

Crude fiber was estimated as

$$\text{Crude fiber\%} = \frac{20.061-20.031}{2} * 100$$

$$= 0.015 * 100$$

$$= 1.5\%$$

Crude fiber in the ice cream sample was found to be **1.5%**

ESTIMATION OF FAT

Fat was estimated as

$$\begin{aligned}\text{Fat\%} &= \frac{96.2 - 96.29776}{1.04} * 100 \\ &= 0.094 * 100 \\ &= 9.4\%\end{aligned}$$

Fat % in the ice cream sample was found to be **9.4 %**

CONCLUSION

Black gram milk was extracted from black gram without peel as it showed good consistency with the help of that milk is reduced and ice cream was prepared and subjected to analysis. Out of several trials the best one was optimized and taken for analysis several external and internal factors were determined, with the help of that it is proved black gram milk is rich in nutritional quality and good for health and a good substitute for normal milk hence it can be used further for development. spirulina can also be used as super food and value added food product.

ABSTRACT

The complex character and high organic content of dairy sector effluents present significant environmental challenges. Fixed bed reactors offer a viable method for treating dairy effluents because of its ability to biologically remove organic pollutants. Computational fluid dynamics (CFD) is a powerful technique that can be used to improve the design and performance of such reactors by modelling the flow patterns and mass transfer within the reactor bed. This work focuses on using CFD analysis to better understand the hydrodynamics and mass transfer processes that occur in a fixed bed reactor used to treat dairy wastewater. The CFD model incorporates the reactor design, flow distribution, and porous media characteristics to mimic the intricate interactions between the biomass attached to the reactor medium and the fluid flow. The pressure distribution, residence time distribution, concentration gradients, and velocity profiles inside the reactor bed are all made clear by the simulation findings. The study assesses the influence of operational factors, such as flow rate, influent concentration, and bed porosity, on reactor performance indicators, which include biomass dispersion, hydraulic efficiency, and pollutant removal efficiency.

ABSTRACT

Plastic pollution has become a global environmental concern, with single-use plastic straws contributing significantly to this issue. To address this challenge, this project focuses on the development of a biodegradable straw using peanut hull, an agricultural waste material abundantly available worldwide. The project aims to provide a sustainable alternative to conventional plastic straws while utilizing agricultural waste, thereby promoting both environmental conservation and resource efficiency. The process involves extracting cellulose from peanut hull through a series of chemical treatments, followed by molding and shaping to form straws. Various parameters such as cellulose extraction efficiency, mechanical properties, and biodegradability are investigated to optimize the production process and ensure the straw's functionality and environmental compatibility. Furthermore, the project assesses the biodegradability of the developed straws under different environmental conditions, including soil and marine environments, to evaluate their potential ecological impact. Comparative analyses with conventional plastic straws are conducted to highlight the environmental benefits of the biodegradable alternative. The outcomes of this project have the potential to offer a sustainable solution to the plastic pollution problem associated with single-use straws while simultaneously addressing the issue of agricultural waste management.

Implementation of biodegradable straws derived from peanut hull could contribute significantly to reducing plastic waste and fostering a more environmentally conscious approach to consumption and waste management practices.

ABSTRACT

Cashew nut roasting before shelling is an important treatment since this roasting operation helps to shell the nuts to extract the kernels easily without damaging the edible kernels. For large scale processing, mechanized/semi-mechanized roasters are available, but for low-capacity processors, getting an economical and low capacity roaster is a challenge. For low-capacity processing, processors opt for open pan/flame roasting method, which causes over roasting (burnt) or under roasting of cashew nuts. The aim of this article was to design and fabricate a low-cost, simple to operate mini cashew nut roaster, which would be applicable for small scale cashew nut processors. A drum roaster was designed and fabricated, on which the experimental trials were conducted by varying the roasting time between 1 and 7 min to determine the best roasting time, where the drum roaster surface temperature was 275 ± 25 °C. From the roasting trials, it was found that fabricated cashew nut roaster was suitable for roasting cashew nuts within 2.5 min. It was low in cost and required no skilled labors for its operation. Sensory analysis of cashew nut, roasted by developed mini cashew nut roaster was found to be acceptable. The developed small capacity roaster was found suitable to address the needs of small-scale cashew nut processors.

ABSTRACT

Garlic (*Allium sativum*) has long been recognized for its numerous health benefits attributed to its bioactive compounds. While much attention has been given to the bulb, recent studies have highlighted the potential of garlic peel as a rich source of antioxidants and antimicrobial agents. This review provides a comprehensive analysis of the antioxidant and antimicrobial properties of garlic peel extracts. It examines the various extraction methods employed to isolate bioactive compounds from garlic peel and evaluates their effectiveness in scavenging free radicals and inhibiting microbial growth. Additionally, this review discusses the mechanisms underlying the antioxidant and antimicrobial activities of garlic peel extracts, including their interactions with reactive oxygen species and microbial cell structures. Furthermore, the potential applications of garlic peel extracts in food preservation, pharmaceuticals, and cosmeceuticals are explored. Overall, this review underscores the significant potential of garlic peel as a natural source of antioxidants and antimicrobial agents, highlighting its promising prospects for various industries and its potential contribution to human health and wellness.

NATURAL SWEETENER FORMULATION FROM LICORICE ROOTS

ABSTRACT

Licorice (*Glycyrrhiza glabra*) roots have been recognized for their medicinal and culinary properties for centuries, owing to the presence of glycyrrhizin, a natural sweetening compound with potent health benefits. However, traditional extraction methods often involve complex procedures and the use of solvents that may pose environmental and health risks. In this study, we present a novel process for the extraction of glycyrrhizin from licorice roots, employing environmentally friendly techniques to enhance yield and purity. The proposed method utilizes a combination of aqueous extraction and purification steps, leveraging the principles of green chemistry. Initially, dried licorice roots are pulverized and subjected to aqueous extraction under optimized conditions of temperature, pH, and time, maximizing the release of glycyrrhizin while minimizing energy consumption. Subsequently, the crude extract undergoes purification through techniques such as filtration, precipitation, and chromatography, to remove impurities and concentrate the target compound. Key parameters such as extraction efficiency, purity of glycyrrhizin, and environmental impact are evaluated to assess the efficacy of the proposed process. Comparative analyses with conventional extraction methods demonstrate superior yield and purity, while reducing the use of hazardous solvents and energy resources. Moreover, the extracted glycyrrhizin exhibits excellent sweetness potency, making it a viable natural alternative to synthetic sweeteners in various food and beverage applications.

ABSTRACT

Synthetic preservatives play a pivotal role in extending the shelf life of food products, preventing microbial spoilage, and maintaining their quality. However, concerns regarding their potential adverse health effects and consumer demand for clean label products have spurred extensive research into their impact on food safety, quality, and consumer perception. This review aims to provide a comprehensive overview of the influence of synthetic preservatives on various aspects of food products, including their efficacy in microbial control, effects on sensory attributes, health impacts, and emerging alternatives. Additionally, it discusses the trends towards natural and clean label alternatives, technological advancements, and future research directions in the field of food preservation.

KEYWORDS

synthetic additives, food preservation, impact on health

INTRODUCTION

The preservation of food products has been a fundamental practice throughout human history, allowing societies to store and transport food items over long distances and periods. In modern food production, synthetic preservatives have

become indispensable in ensuring the safety and quality of a wide range of food products. These additives inhibit microbial growth, delay spoilage, and maintain product freshness, thereby extending shelf life and enhancing consumer convenience. However, the widespread use of synthetic preservatives has raised concerns among consumers, health professionals, and regulatory authorities. Questions about their potential adverse health effects, environmental impact, and contribution to food allergies and sensitivities have prompted reevaluation of their safety and necessity in food production. Furthermore, the growing demand for natural and minimally processed foods has fueled interest in alternative preservation methods that align with consumer preferences for clean label products. This review aims to critically examine the influence of synthetic preservatives on food products, considering their efficacy, safety, regulatory status, and impact on sensory attributes.

PRESERVATIVE

Preservatives are additives used in food to prevent spoilage, extend shelf life, and maintain freshness by inhibiting microbial growth and oxidation.

Synthetic preservatives

Synthetic preservatives in food are chemical compounds added to inhibit microbial growth, extend shelf life, and maintain freshness. These additives help prevent spoilage, preserve flavor, and ensure food safety by delaying oxidation and microbial contamination. While effective, concerns have been raised about their potential health impacts, leading to increased interest in natural alternatives.

ANTIMICROBIAL AGENTS

Antimicrobial agents are commonly used in food preservation to inhibit the growth of microorganisms, such as bacteria, fungi, and yeast, thereby extending the shelf life of food products. These agents work by disrupting microbial cell membranes, inhibiting enzyme activity, or altering cellular pH, preventing the growth and proliferation of harmful microorganisms in food.

Impact in Food products

One common synthetic preservative is sodium benzoate, which is used in various foods and beverages such as soft drinks, fruit juices, and condiments. Sodium benzoate inhibits the growth of bacteria and mold by lowering the pH of the food product, creating an environment where microorganisms cannot thrive. Another example is butylated hydroxy anisole (BHA) and butylated hydroxytoluene (BHT), which are often used together or separately in food products such as cereals, snack foods, and processed meats.

Inhibition of Microbial Growth: Synthetic antibacterial substances can inhibit the growth of bacteria, yeast, mold and other organisms in foods. This inhibitory effect helps prevent spoilage and extends the shelf life of the food.

Texture Care: Antimicrobial substances help preserve the texture of the food by preventing bacterial growth. For example, they prevent the formation of slime or mold that would spoil the food.

Color Preservation: Antibiotics can help preserve the color of food by inhibiting microbial growth and preventing enzymatic browning. This helps preserve the visual appearance of the food for longer.

Flavor Stability: Synthetic antimicrobials help preserve the flavor of food by preventing microbial spoilage that can cause off-flavors or off-flavors. They ensure that the food maintains the desired flavor throughout its shelf life.

Nutrition Preservation: Antibiotics help preserve the nutritional value of food by inhibiting the growth of bacteria. This is especially important for foods that are rich in nutrients and can be easily broken down by microorganisms.

Consistency and Stability: Synthetic antimicrobials contribute to the overall consistency and stability of food by preventing microbial spoilage and controlling adverse effects such as texture, color, taste and aroma.

Impact in shelf life: The synthetic antimicrobial agents help delay the spoilage by creating an inhospitable environment for microbes to thrive, thus preserving the freshness and edibility of food.

ANTIOXIDANTS

Synthetic antioxidant preservatives are compounds used in food products to prevent or delay oxidation, which can lead to rancidity and deterioration of flavor, color, and texture. TBHQ is a synthetic antioxidant commonly added to oils, fats, and processed foods to prevent oxidation and extend shelf life. It's often found in products like snack foods, fast food, and instant noodles.

Octyl gallate is used as an antioxidant preservative in fats, oils, and processed foods to prevent oxidation and extend shelf life, particularly in products like margarine, salad dressings, and snack foods.

Impact on food products

Flavor Preservation: Synthetic antioxidants like BHA and BHT are commonly added to the oil used for frying potato chips. By preventing oxidation of the oil, these

antioxidants help maintain the desired flavor profile of the chips, ensuring they taste fresh and savory.

Color Retention: Without synthetic antioxidants, the oil used for frying potato chips would oxidize, leading to the development of off-colors and a darker appearance in the chips. However, with the addition of antioxidants, the oil remains stable, preserving the golden-brown color of the chips and maintaining their visual appeal.

Texture Maintenance: Oxidation of the oil in potato chips can lead to changes in texture, making them greasy or stale. Synthetic antioxidants prevent this oxidation, helping to maintain the crisp and crunchy texture of the chips, enhancing the overall eating experience for consumers.

Extended Shelf Life: By inhibiting oxidation, synthetic antioxidants help extend the shelf life of potato chips. This ensures that the chips remain fresh and crispy for a longer period, reducing the likelihood of them becoming stale or rancid before consumption.

Stability: Synthetic antioxidants contribute to the stability of potato chips during storage and transportation. They protect the chips from oxidative deterioration, ensuring that they maintain their quality and integrity throughout the distribution chain, from production to the consumer's pantry.

Nutritional Preservation: Synthetic antioxidants help preserve the nutritional content of potato chips by preventing oxidation-related nutrient loss. This ensures that consumers receive the intended nutritional benefits from the chips, such as vitamins and minerals, without degradation during storage.

Processing Efficiency: Synthetic antioxidants improve the efficiency of potato chip manufacturing by stabilizing the oil used for frying. This reduces the need for frequent oil changes and minimizes production downtime, leading to cost savings and increased productivity.

CHELATING AGENT

A chelating agent is a chemical compound that forms stable, water-soluble complexes with metal ions by surrounding them and binding tightly. These compounds contain multiple sites capable of binding to metal ions, forming a ring-like structure known as a chelate. Chelating agents are used in various industries, including food, pharmaceuticals, and water treatment, for purposes such as removing metal impurities, preventing oxidation, and improving stability.

Impact on food products

Flavor Preservation: Synthetic antioxidants such as BHA and BHT are often added to the oil used to fry potato chips. Antioxidants help maintain the desired profile of potato chips by preventing the oxidation of oil, so they taste fresh and delicious.

Color Protection: Without synthetic antioxidants, the oil used to fry potato chips oxidizes, causing the chips to appear colorless and dark. However, when antioxidants are added, the oil remains stable, preserving the yellow color of the chips and keeping them looking their best.

Texture Care: Oxidation of the oil in potato chips can cause texture changes, making them greasy or stale. Synthetic antioxidants prevent this oxidation, helping preserve the texture of the potato chips and increasing their overall nutritional value for the consumer.

Extended shelf-life: Synthetic antioxidants help extend the shelf life of potato chips by preventing oxidation. This keeps the chips fresh and crispy for a long time, reducing the chance of them spoiling or going rancid before eating.

Stability: Synthetic antioxidants help increase the stability of potato chips during storage and transportation. By protecting potato chips from oxidative degradation, they ensure that their quality and integrity are maintained throughout the chain from production to the consumer.

Nutrition Preservation: Synthetic antioxidants help preserve the nutritional value of potato chips by preventing nutrient loss due to oxidation. This ensures that consumers receive nutritional benefits such as vitamins and minerals from the chips without degrading during storage.

Efficacy: Synthetic antioxidants can improve the performance of potato chips by stabilizing frying oil. This reduces the need for frequent oil changes and reduces operating hours, saving costs and increasing productivity.

IMPACT ON CONSUMER HEALTH

Synthetic food preservatives play a crucial role in extending the shelf life of food products, but their impact on human health can be a topic of concern

BHA and BHT have been shown to have carcinogenic properties in animal studies, and while the evidence in humans is less conclusive, there are concerns about their potential impact on human health, particularly with long-term exposure.

sodium nitrite, commonly used as a preservative in processed meats, has been associated with an increased risk of certain cancers, such as colorectal cancer, when consumed in high amounts.

ALTERNATIVES

Vinegar: Its acidic nature inhibits the growth of bacteria and fungi.

Salt: It dehydrates microbes and slows down their growth.

Sugar: High concentrations of sugar inhibit microbial growth by reducing water availability.

Citric acid: It is commonly used as a preservative in foods due to its acidic properties.

Rosemary extract: Contains natural antioxidants that can prevent oxidation and spoilage.

Fermented ingredients: Fermented foods contain natural preservatives like lactic acid and bacteriocins that inhibit the growth of harmful bacteria.

Essential oils: Some essential oils, such as oregano, thyme, and clove, have antimicrobial properties and can be used as natural preservatives.

Plant extracts: Extracts from plants like grapefruit seed, green tea, and garlic have been shown to have antimicrobial properties and can be used as natural preservatives. These alternatives can limit the usage of synthetic preservatives.

RECENT ADVANCEMENT

A recent development in synthetic food preservation involves the utilization of antimicrobial peptides (AMPs). These peptides, which naturally occur in various organisms including plants, animals, and humans, exhibit broad-spectrum antimicrobial properties against bacteria, fungi, and certain viruses.

Researchers have been exploring ways to leverage AMPs for preserving food. They can be synthesized or produced using biotechnological methods and then incorporated into food packaging materials or directly added to food items. AMPs offer several benefits as food preservatives:

Wide-ranging antimicrobial action: AMPs can effectively target a diverse array of microorganisms, including those responsible for food spoilage and pathogenicity.

Reduced risk of microbial resistance: Unlike conventional antibiotics, AMPs typically interfere with microbial cell membranes or essential structures, making it challenging for microorganisms to develop resistance.

Natural origin: Many AMPs are derived from natural sources, enhancing their appeal to consumers who prefer natural or minimally processed food products.

Potential for targeted delivery: Advances in nanotechnology enable the encapsulation or immobilization of AMPs, facilitating their precise delivery to specific regions of food products or packaging materials.

CONCLUSION

The preservation of food products is a critical aspect of modern food production, ensuring safety, quality, and extended shelf life. This review has explored the efficacy, safety, regulatory status, and impact of synthetic preservatives on food products, alongside natural alternatives and recent advancements such as antimicrobial peptides (AMPs). Moving forward, a balanced approach that considers both the benefits and risks of synthetic preservatives, while exploring natural alternatives and innovative solutions like AMPs, will be essential in meeting consumer preferences for safe, natural, and minimally processed foods. Collaborative efforts between industry, regulators, and researchers are crucial to ensuring food preservation methods align with consumer health, environmental sustainability, and product quality standards.

ABSTRACT

The increasing consumer interest in plant-based diets has propelled the growth of the vegan meat industry, with a plethora of products entering the market. This comprehensive review examines the consumer and market impact of vegan meat products, encompassing factors such as consumer preferences, purchasing behavior, health perceptions, environmental concerns, and market trends. Through a synthesis of existing literature and market data, this review elucidates the drivers behind the rising demand for vegan meat alternatives and evaluates their potential to disrupt traditional meat markets. This shift is driven not only by strict vegans or vegetarians but also by flexitarians aiming to reduce their meat consumption for various reasons.

KEYWORDS

Plant-based diets, Vegetarians, Meat alternatives, Traditional meat market

INTRODUCTION

The global trend towards sustainable and ethical food choices has led to a surge in interest in vegan meat products. With consumers increasingly aware of the environmental, health, and ethical impacts of their food choices, there's a growing demand for plant-based alternatives to traditional meat, not only by strict vegans or

vegetarians but also aiming to reduce their meat consumption for several health impacts.

The market for vegan meat products is booming, characterized by innovative offerings that replicate the taste, texture, and nutritional profile of conventional meat. From burgers to sausages and even seafood substitutes, companies are catering to diverse consumer preferences. The consumer and market impact of vegan meat products by analyzing factors such as consumer attitudes, purchasing behavior, health perceptions, environmental concerns, and market dynamics.

The demand for vegan meat products, emphasizes future of food consumption and the role of plant-based alternatives. Moreover, by examining market trends and industry developments, it is identified that the strategic implications for businesses, policymakers, and other stakeholders navigating this evolving landscape.

VEGAN MEAT PRODUCT

Vegan meat or plant-based meat or mock meat or fake meat refers to plant-based food products that replicate the taste, texture, and appearance of traditional meat without using animal-derived ingredients. Popular plant-based protein sources used in vegan meat include soy, wheat gluten (seitan), peas, beans, and mushrooms. Vegan meat is often lower in saturated fat and cholesterol compared to animal meat. It is free from hormones and antibiotics typically found in conventional meat products.

Some vegan meat brands prioritize organic and non-GMO ingredients in their products. Vegan meat is often cruelty-free, as it does not involve the slaughter of animals. Vegan meat can come in various forms such as vegan burgers, plant-based sausages, meatless meatballs, vegan deli slices, plant-based nuggets, vegan hot dogs, and meatless ground meat. These options offer consumers diverse culinary experiences while supporting dietary preferences, health, environmental sustainability, and ethical considerations.

CURRENT STATUS OF VEGAN MEAT

The global plant-based meat market was valued at over \$12 billion in 2020, with projections indicating continued growth at a CAGR of over 15% from 2021 to 2027. This data shows the promising future of vegan meat products as viable alternatives to traditional meat.

Major food companies are heavily investing in plant-based alternatives, driving rapid expansion in the market. Leading brands like Beyond Meat and Impossible Foods have gained mainstream acceptance, with widespread distribution in grocery stores and partnerships with fast-food chains and restaurants. This trend reflects increasing awareness of the environmental, health, and ethical concerns associated with meat consumption, coupled with a rising number of individuals adopting plant-based diets or reducing their meat intake.

CONSUMER PERCEPTION ON VEGAN MEAT PRODUCTS

Vegan meat products positively, appreciating their lower environmental footprint, potential health benefits, and alignment with ethical values, such as animal welfare and sustainability. Vegan meat products were influenced by factors such as taste, health considerations, environmental impact, and ethical concerns. They may also enjoy the variety of flavors and textures offered by vegan alternatives.

However, other consumers may have reservations about vegan meat products, citing concerns about taste, texture, and nutritional value compared to traditional meat. In regions with strong culinary traditions centered around meat consumption, acceptance of vegan meat products may be slower compared to areas with a more diverse and plant-focused diet.

Consumer perceptions of vegan meat products are evolving as awareness grows and product offerings improve. Continuous efforts have taken to enhance taste, texture, and nutritional profiles, along with education about the benefits of plant-based diets, are likely to influence consumer attitudes positively towards vegan meat alternatives over time.

SOURCES OF VEGAN MEAT PRODUCT

JACKFRUIT

Jackfruit is a tropical fruit known for its fibrous texture, which makes it a popular meat substitute in vegan and vegetarian cooking. When cooked, the texture of jackfruit resembles pulled pork, making it suitable for dishes like barbecue sandwiches or tacos. Jackfruit takes on the flavors of the seasonings and sauces it's cooked with, making it versatile for a variety of recipes.

SEITAN

Seitan also known as wheat meat or wheat gluten, seitan is a meat substitute made from gluten, the protein found in wheat. It has a chewy texture and a savory flavor, making it similar to the texture of meat. Seitan can be seasoned, marinated, and cooked in various ways, including grilling, frying, or simmering in soups and stews. It's a popular ingredient in many vegetarian and vegan dishes, providing a substantial source of protein.

TEMPEH

Tempeh is a traditional Indonesian food made from fermented soybeans. It has a dense, nutty texture and a slightly earthy flavor. Tempeh is rich in protein, fiber, and various nutrients, making it a nutritious meat alternative. It can be sliced, marinated, and cooked in a variety of ways, such as grilling, stir-frying, or baking. Tempeh absorbs flavors well and can be used in dishes ranging from sandwiches to stir-fries.

TOFU

Tofu, also known as bean curd, is made from soybeans and is a staple in vegan and vegetarian diets. It has a soft, creamy texture and a mild flavor, making it a versatile ingredient in a wide range of dishes. Tofu can be pressed to remove excess water and then seasoned or marinated to mimic the flavors of meat. It can be used in stir-fries, soups, salads, and even desserts, depending on the type of tofu and how it's prepared.

TEXTURED VEGETABLE PROTEIN

TVP is made from defatted soy flour that has been processed into granules or chunks. It has a meat-like texture and is often used as a meat extender or substitute in recipes like chili, tacos, or spaghetti sauce. TVP is inexpensive, shelf-stable, and high in protein, making it a popular choice for vegetarian and vegan cooking. It can be rehydrated and seasoned to add texture and protein to a variety of dishes.

These are products made from a combination of plant-based ingredients such as soy, wheat gluten, pea protein, and mushrooms. They are often designed to mimic the taste, texture, and appearance of traditional animal-based meats like beef, chicken, or pork. Plant-based meats have gained popularity due to their ability to provide a familiar eating experience for those transitioning to a vegan diet or looking to reduce their meat consumption.

IMPACTS OF VEGAN MEAT PRODUCT ON CONSUMERS

Many consumers are increasingly concerned about their health and are opting for plant-based alternatives as they perceive them to be healthier than traditional meat.

Vegan meat products often contain lower levels of saturated fats and cholesterol, making them a popular choice for health-conscious individuals. A vegetarian diet offers numerous health advantages due to its rich fiber, folic acid, vitamins C and E, potassium, magnesium, and various phytochemicals. Additionally, its fat content is predominantly unsaturated. However, vegans should pay special attention to obtaining adequate levels of certain micronutrients, including vitamins B-12 and calcium, and long-chain n-3 (omega-3) fatty acids while consuming plant based meat.

It provides an alternative source of protein and nutrients for those looking to reduce their reliance on animal products or follow a plant-based diet.

RECENT ADVANCEMENT

Advancements in vegan food products have made it easier than ever for individuals to adopt a plant based diet or incorporate more plant based options into their diet. Advances in food processing technology have played a crucial role in the development of vegan food products. Techniques such as extrusion, fermentation, and high pressure processing have been used to create plant based alternatives with desirable textures, flavors and nutritional profiles. These technologies have also enabled manufacturers to scale up production and meet the growing demand for vegan products. Dairy alternatives such as almond milk, soymilk, oat milk, and coconut milk whereas by-products of dairy is vegan cheese made from nuts, soy or tapioca are becoming increasingly available and are improving in taste and texture. These alternatives not only cater to individuals with lactose intolerance or dairy allergies but also to those looking to reduce their consumption for health or ethical reasons. Egg substitutes such as tofu scrambles, chickpea flour-based scrambles and commercial products like just egg, which also offers a alternatives for baking and cooking.

Some notable advancements include plant-based seafood and many convenience foods. Plant based seafood includes fish fillets, shrimp, and crab cakes using ingredients like seaweed, soy protein and konjac. The market for vegan convenience foods such as frozen meals, ready-to-eat snacks, pre- packaged meals, has expanded significantly, providing more options for consumers looking for quick and easy plant-based options.

CONCLUSION

The surge in consumer interest in plant-based diets has led to significant growth in the vegan meat industry. This review highlights the factors driving this trend, including health concerns, environmental awareness, and ethical considerations. It also discusses the current status of the vegan meat market, which is projected to continue growing rapidly. Consumer perceptions of vegan meat products are

evolving, with many appreciating their lower environmental footprint and potential health benefits, although some still have reservations about taste and texture. Advancements in food processing technology have led to the development of a wide range of vegan alternatives, including dairy and egg substitutes, as well as plant-based seafood and convenience foods. Overall, the future looks promising for vegan meat products as they offer consumers diverse culinary experiences while supporting health, sustainability, and ethical considerations.

ABSTRACT

Colour is a measure of quality and nutrient content of foods. The objective of adding colour to foods is to make them appealing, augment the loss of colour during processing, to improve the quality and also to influence the consumer to buy a product. At present, the demand for natural dyes is increasing worldwide due to the increased awareness on therapeutic and medicinal properties and their benefits among public and also because of the recognized profound toxicity of synthetic colours. Natural dyes are those derived from naturally occurring sources such as plants, insects, animals and minerals. Among all the natural dyes, plant-based pigments have medicinal values so are mostly preferred. Today the food industry and color suppliers are however constantly motivated to work towards the improvement of the technical and physical properties of the color preparations. Development of costeffective, viable technology for the preparation of a food color and its application in foods is a challenge.

KEYWORDS

Food colourant, Nutritional properties, viable technology.

INTRODUCTION

Today's consumers are proactively seeking food products that contain 'safe' ingredients in them. Colour is one of those important ingredients upon which the quality of food and flavour can be judged. (Bakry, A.M et al. 2016). International Conference on Adaptive Technologies for Sustainable Growth © ICATS 2021

These food colours are any substance that is added to food or drink to change its colour for acceptability. These are derived from both artificial and natural sources in varied intensities. (Chung, C. et al. 2015) The objective of the addition of colour in food is to make the food more appealing and recognizable. Everyone is sensitive to the colour of the food as it can stimulate or suppress one's appetite. Artificial colours when added to food products possesses very bright and tempting effect, but very often are responsible for specific teratogenic and carcinogenic affects (Rehman, F. et al. 2018). Potential sources of artificial food colours are mineral compounds, petrochemicals, petroleum, and coal tar which leads to many harmful diseases like attention deficit hyperactivity disorder (ADHD), brain tumours etc. (Umbreen, S, et al. 2008). Thus, the natural colour market is currently going twice as fast as that of artificial colours. It has been observed that within last 10 - 15 years, there has been a distinct move towards naturals, especially within flavours and colours. Natural food colours not only give an appealing and appetizing look but also possesses varied nutritional and health benefits. (Peris, C.S., et al. 2018). Our work is to extract colour from *Portulaca grandiflora* flower which have antioxidant property, antidiabetic property. An extract of *P.Grandiflora* has potential to treat hepatitis, liver cirrhosis. (Carvalho, M.J., et al. 2015). The aim is to extract the pigment from the flower and to analyse the beneficial functions of the flower pigment of *P.Grandiflora*.

METHODOLOGY

Portulaca grandiflora flower was collected from the premises of various streets and neighbour's houses near dindigul. The samples were carefully washed using distilled water and collected petals were dried at room temperature. 1g of dry petals were taken and 50ml of water was introduced in a glass beaker to immerse the petals into the solvent fully. (Carocho, M., et al. 2014).

CHARACTERIZATION

The flower samples were characterized by some equipment's. They are, FTIR analysis, UV spectroscopy and Thin Layer Chromatography.

FTIR Analysis

Fourier transform infrared (FTIR) was used to identify the characteristic functional groups in the extract. It provides the information about the structure of a molecule could frequently be obtained from its absorption spectrum. A small quantity of the extract was mixed in dry potassium bromide (KBr). The mixture was thoroughly mixed in a mortar and pressed at a pressure of 6 bars within 2 min to form a KBr thin disc. Then the disc was placed in a sample cup of a diffuse reflectance accessory. The IR spectrum was obtained using Bruker, Germany Vertex 70 infrared spectrometer. The sample was scanned from 4000 to 400 cm^{-1} (Pramila., 2012).

The peak values of FTIR were recorded.

FTIR Spectroscopy

UV Spectroscopy

UV-visible spectrophotometric analysis was conducted on the extract using a UV-visible spectrophotometer (Perkin Elmer, USA Model: Lambda 950) with a slit width of 2nm, using a 10-mm cell at room temperature. The extract was examined under visible and UV light in the wavelength ranging from 300-800nm for proximate analysis. For UV-VIS spectrophotometer analysis, the extract was centrifuged at 3000 rpm for 10 min and filtered through Whatman No. 1 filter paper. The sample is diluted to 1:10 with the same solvent. (Karpagasundari and Kulothungan, 2014). The peak values of UV-VIS Spectroscopy were recorded.

UV – Spectroscopy

Thin Layer Chromatography

The TLC plates supplied by Merck, Germany (TLC Silica gel 60 F254) was used to observe the separation of different compounds were trimmed and the position of the origin marked by a straight line. The column fractions of sample were spotted on the origin and put in a lidded tank containing a solvent system. The procedure was followed with other plates and various solvent-solvent ratios (chloroform: methanol in the ratio 9:1 and 8:2) until good resolution was noticed. The level of solvent in the tank was about 1cm beneath the origin. The solvent travelled up the plate by capillary action till it reached the solvent front (also marked by a straight line across). The lid was lifted off and the plate is dried before it was viewed by spraying with silver nitrate and iodine vapour and visualized under UV light to identify and confirm the compounds eluted through column chromatography.

RESULT AND DISCUSSION

The composition of natural dyes has been affirmed using FTIR spectroscopy, has been completed. The analysis of the FTIR spectra of the two sample has been described below. Since various peaks obtained.

In FTIR analysis, the two samples are approximately very similar. The main difference between the samples is flower colour. In spectrum (a and b samples), the observed stretching band of various functional groups.

In UV Spectroscopy analysis, the two samples are approximately very similar. The main difference between the samples is flower colour. In spectrum (a and b samples), the conclusion was observed based on the presence of the phenolic compounds and to measure the amount of light absorbtion by the bioactive composunds present in the flower extract and to identify the compounds in wavelength range of 300 – 800nm (purple) and 350 – 500nm (yellow). In graph, the sharpness and broadness of peaks depends on the extent of hydrogen bonding present in the molecule.

In spectrum (a – purple sample), it was analyzed that the obtained absorption spectrum was sharp with varying intensities, the sharp peak of *Portulaca grandiflora* colour solution is at the wavelength (300 – 800nm) of 232.42, 351.17 respectively. These two different peaks was obtained due to high electron transition.

In spectrum (b – yellow sample), it was analyzed that the obtained absorption spectrum was observed with varying intensities, the highest peaks of *Portulaca grandiflora* colour solution is at the wavelength (350 – 500nm) of 389.37, 438.01 respectively. These two different peaks was obtained due to high electron transition.

In Thin Layer Chromatography analysis, the main difference between the samples is flower colour. In this analysis (a and b samples), the conclusion was observed that the flower has various bio-active compounds based on the colour separation in the

TLC plate. In spectrum (b – purple sample), it was analyzed that the colour separation was observed from amarnath purple like green, pink, blue, purple, etc. it is due to the presence of compounds like anthocyanins, chloryll, betalains etc in the flower sample.

In spectrum (b – yellow sample), it was analyzed that the colour separation was observed from like yellow colour extract like blue, light green, pale yellow, orange red etc,. due to the presence of betalains, chlorophyll, carotenoids, proteins.

CONCLUSION

In this project, The pigment was extracted from *Portulaca grandiflora* in the form of natural food colorant. The aim of our work is to increase the stability and shelf life of the natural food colorant. We have undergone several analysis to study the characterization of natural pigment. FTIR was assessed for stability and formulation development from the pigment. UV spectroscopy was analyzed which uses the pH and temperature to create the impact on food products during incorporation. TLC was done to identify the purity and separation of colours by comparing the intensity of spots in the plate. From the various analysis, we concluded that The purple flower extract has higher stability then the yellow flower extract due to the presence of various functional groups and their light absorption capacity.

ABSTRACT

In the realm of food preservation, the development of sustainable and efficient methods is crucial to combat food waste and meet the demands of a growing population. This abstract explores the fabrication of biofilm as a promising solution for preserving perishable foods. Biofilm, composed of natural polymers and bioactive compounds, offers a protective barrier against microbial growth and oxidation, thereby extending the shelf life of perishable products. This paper reviews the fabrication techniques, including casting, extrusion, and electrospinning, utilized to create biofilms with tailored properties such as mechanical strength, barrier properties, and antimicrobial activity. Additionally, the incorporation of bioactive agents such as essential oils, antimicrobial peptides, and plant extracts enhances the biofilm's efficacy in preserving food quality. Furthermore, the potential applications of biofilm in various food products, including fruits, vegetables, meat, and dairy, are discussed, highlighting its versatility and adaptability to different food matrices. Overall, the fabrication of biofilm represents a promising avenue for sustainable food preservation, offering both environmental benefits and economic advantages in reducing food waste and enhancing food safety.

DEVELOPMENT OF BIO-FILM USING FOOD WASTE

ABSTRACT

Food packaging refers to how food items are placed, the packed materials used and the technology that makes it possible. Food packaging design is crucial to guarantee food safety throughout the supply chain, optimize storage and transportation and facilitate the communication of product information to retailers and customers. More sustainable food packaging design aims for minimum environmental burden at the end-of-life of the food product and package. In the recent, advancement technology, packaging material are obtained from food waste which is an additional advantage for the product safe and also reusing waste known as biodegradable films, edible films etc. Numerous research has been in progress on bio-based films which have properties that does not affect the quality of the product also enhances the quality of packaging material which is environmentally friendly. So, in this mixed food waste are taken and addition of other materials to obtain a bio film. Extensive quantity of fruit pomace is generated annually but its disposal is still challenging. Solution casting was applied to form bio- based films. Keywords: biofilm, biodegradable, lemon pomace, biomaterials, solution casting.

INTRODUCTION

Bio film packaging is an eco-friendly packaging solution that utilizes biodegradable materials to create a protective film around products. Biofilm packaging is designed to biodegrade more quickly, often within a few months or to a few years, depending on environmental conditions. Biofilm packaging can be designed to meet food safety standards, ensuring that it does not compromise the

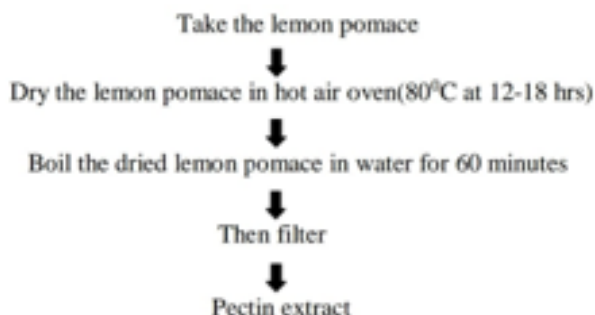

quality or safety of the products it contains. It is important to note that specific characteristics of a biofilm packaging can vary depending on the materials and manufacturing processes used. Pomegranate pomace properties refers to the remnants or byproducts of processing pomegranates, typically after the extraction of juice or seeds. Pomegranate pomace can be further processed or repurposed for various application including its use as a source of antioxidants. which is mainly due to the presence of polyphenols, particularly ellagic acid and anthocyanins. Pomegranate pomace can be incorporated into biodegradable or compostable packaging materials to enhance their visual appeal and sustainability. Lemon pomace is often considered a byproduct of lemon processing. Lemon pomace contains antioxidants, such as flavonoids, which contribute to its potential health benefits. Lemon pomace contain trace amounts of minerals and vitamins, such as vitamin C. Lemon pomace is rich in dietary fiber, including both soluble and insoluble fibers. Lemon pomace is biodegradable and can be composted, contributing to sustainable waste management. Bagasse is the fibrous residue left behind after sugarcane or similar plants have been crushed to extract their juice. Its primarily composed of cellulose, lignin, and hemicellulose. Bagasse has various uses, including as a source of renewable energy in the form of biofuel or for the production of paper, cardboard and building materials.

Glycerol also called as glycerin, is a simple triol compound. Glycerol is generally obtained from animal sources where it occurs in triglycerides, esters of glycerol with long-chain carboxylic acids. Glycerol is highly soluble in water and can also dissolve in various organic solvents. It has high boiling point and low volatility. Glycerol is hygroscopic, it makes an effective moisturizing agent. Glycerol is added to packaging films to help retain moisture within the packaged products. Glycerol act as a plasticizer in packaging films, making them more flexible and less prone to becoming brittle over time. Gelatin is translucent, colorless, flavorless food ingredient commonly derived from collagen taken from animal body parts. Gelatin

can be used in packaging film as a biodegradable and edible film material. It has been explored for various food packaging applications. Gelatin films can protect and extend the shelf life of certain food products, but they have limitation particularly regarding moisture sensitivity. Starch can also be used in packaging films as a biodegradable and environmentally friendly alternative to traditional plastic films. Starch-based packaging films are often combined with other additives to improve their properties such as flexibility and water resistance. These films are biodegradable and can help to reduce the environmental impact of single-use plastic packaging. Starch is used as a primary component in packaging films. It provides the basic structure and mechanical strength required for packaging. Citric acid can be added to packaging films to enhance their biodegradability. When combined with biopolymers like starch or cellulosic, citric acid can accelerate the decomposition of the film in natural environments, reducing its environmental impact.

LEMON POMACE

Waste lemons are collected and sorted. Then the pomace of the lemon is removed. After removal of pomace, they are weighed using weighing balance. Then they are moved to boiling process. Boiling the pomace of the lemon in water for 60 minutes helps in extraction of pectin.

POMEGRANATE POMACE

Waste pomegranate is collected and sorted. Then the edible part is removed. It is weighed using measuring balance. Then it is further processed.

BAGASSE

Bagasse is the dry pulp fibrous material that remains after crushing sugarcane. The dried bagasse is taken and chopped. Add bagasse and water in ratio of 1:10. Then add NaOH/KOH to the mixture. Heat it for 30 minutes to 2 hours. After alkali treatment, filter the biomass and collect the solid bagasse. Wash it thoroughly with water to remove dissolved lignin and alkali. Then it is dried at 60 – 80 °C in hot air oven. After it is completely dried it grinded into fine powder.

MATERIALS AND METHODOLOGY FOR THE DEVELOPMENT OF BIO-FILM

- Extracted pectin from lemon pomace

- Bagasse powder
- Pomegranate pomace powder
- Glycerin
- Gelatin
- Citric acid
- Distilled water
- Starch

Collection of raw materials

Fruits like pomegranate and lemon were collected. Along with these Bagasse also was collected. Then they were sorted and good quality fruits were selected. They are washed and peeled. Then they are processed.

DRYING

Pomegranate pomace was dried in hot air oven for 12- 18 hours at temperature (80°C). When drying a pomace, it is carried out in aluminium foil. By drying the fruit pomace in hot air oven, moisture content will be completely removed which helps in eliminating microorganisms.

GRINDING

The primary purpose of grinding is to reduce the particle size and breaking a large particle to tiny, small particle. Then the pomegranate pomace was converted into a fine powder.

SIEVING

Sieving helps to obtain fine powder without leaving any large particles. Sieving is a method of using a sieve to distinguish small particles from bigger particles.

PREPARATION OF THE SOLUTION

Take the extracted pectin from lemon pomace and the bagasse powder, which the lignin is removed. Then add the pomegranate pomace powder in the ratio of 2:1:1. After this add 15 ml of distilled water. Then add glycerol of 30%. Add citric acid as

a cross-linking agent of 5%. Add gelatin and mix the solution. Heat the solution without getting lumps. Stir it continuously.

SOLUTION CASTING

The solution was poured into a non-sticky plate for casting. It was filtered in-order to remove any unwanted particles. By using metal kitchen sieve, sir bubbles were removed before pouring into the plate. It was left undisturbed for days.

DRYING

It can be dried in oven at 50°C or hot air dryer for 12-18 hours. Also, it can be dried without using oven at room temperature for 2-3 days.

METHODOLOGY FLOW CHART

RESULTS AND DISCUSSION

The presence of moisture content in food packaging systems can lead to food contamination. In this film the moisture content will be very less so, it is better than other biofilm.

$$\begin{aligned}\text{Moisture content} &= \frac{\text{wet- dry}}{\text{wet weight}} \times 100 \\ &= \frac{0.62 - 0.38}{0.62} \times 100 \\ &= 38.7\%\end{aligned}$$

S.NO	TIME (hr)	WEIGHT (g)
1.	1	0.62
2.	2	0.39
3.	3	0.38
4.	4	0.38

SWELLING INDEX

In this bio film the swelling index capacity is good compared to other biofilm.

$$\text{Swelling index (\%)} = \frac{A - B}{B} \times 100$$

B

$$= 1.7 - 1.3 \times 100$$

$$= 30.1 \%$$

S.NO	TIME (min)	WEIGHT (g)
1	0	1.3
2	5	1.7
3	10	1.9
4	15	1.95
5	20	2.2

BIODEGRADABILITY TEST

The results of our biodegradable test showcased a nuanced perspective on how biofilms interact with the tested material over the course of week, contributing to our understanding of its sustainability profile.

SOLUBILITY TEST

The biofilm was subjected to a solubility test by immersing it in distilled water, revealing its notable ability to dissolve upon contact with the aqueous medium. Observable changes in the biofilm's physical appearance such as a gradual breakdown or disintegration, indicated a clear responsiveness to water solubility during the experimental assessment.

TEAR RESISTANCE

The tear resistance test measures the force required to tear a sample material such as film or sheeting. This test helps to determine the strength of the sample. This test complies with the following standards: ASTM D1004 Standard Test method for initial tear resistance of film

S.NO	SAMPLE	TEAR RESISTANCE (TRIPLICATE VALUE)

TENSILE STRENGTH

The tensile test was performed at ambient temperature using a VICTOR Material Testing Equipment (Model VEW 2302; Jinan, China) based on ASTM D882. The tensile strength samples were cut into rectangular shape with dimensions of 100 \times 15 mm² for each sample with different compositions. The test was carried out at a constant crosshead speed of 5 mm and the load cell was 10 kinds of an average specimen for each formulation was tested and the tensile properties were recorded.

MICROBIAL ANALYSIS

For the isolation of bacteria, different types of media were used. The common media used during the study were blood sugar, nutrient agar, Mac Conkey agar,

Mannitol salt agar, Eosin methylene blue medium, nutrient broth, Triple sugar iron agar, Simon citrate agar, Tryptophan broth and MR-VP broth biochemical media were used. The media for the laboratory analysis were prepared according to standard procedures recommended by Quinn et al., (2002).

Inoculated plates were incubated aerobically at 37°C. After 24 hours of incubation, the plates were removed from the incubation and examined visually. Any growth, pigmentation, hemolysis and colonial morphology were noted accordingly.

CFU/ m L = Number of colonies counted / (dilution factor × volume of sample plated for analysis)

SHELF - LIFE ANALYSIS

Accelerated Stability Testing

To stimulate the effects of long-term storage under accelerated conditions. Samples exposed to elevated temperatures, humidity, and light to accelerate degradation process. Monitor samples periodically over a specified period and assess changes in physical, chemical, and microbial properties such as colour changes, pH, viscosity alterations, microbial growth and changes in chemical composition.

SEM ANALYSIS

The morphological features of the sample were studied by Scanning Electron Microscope. After 24 hours of the preparation of SEM slides were prepared by making a smear of the solution slides. A thin layer of platinum was coated to make the sample conductive. Then the samples were characterized in the SEM at an accelerating voltage of 20 KV.

CONCLUSION

Pomace solution casting and compression molding techniques were effectively utilized in creating biofilms from pomace and bagasse. The selection of plasticizer significantly influenced the properties of the products. Glycerol usage led to films and fiberboards with enhanced tensile strength. Employing naturally occurring resulted in products with a more interconnected structure. However, for films, it led to significantly increased elongation at maximum tensile strength. Utilizing lemon pomace for producing eco-friendly materials offers a promising solution to plastic pollution and pomace disposal issues. These innovative materials hold potential for various applications, such as edible packaging.

ABSTRACT

In today's fast-paced world, we often overlook the power of food in promoting health and well-being. But the truth is, the food we consume plays a crucial role in preventing and managing various health conditions. By embracing the concept of food as medicine, we prepared biotin cake to nourish our bodies and promote optimal health. It's a powerful reminder that what we eat can have a profound impact on our well-being. Our biotin-infused cake is a delightful blend of moist, fluffy layers infused with the goodness of this essential vitamin. With each bite, you'll experience a burst of flavors that tantalize your taste buds while promoting healthy hair, radiant skin, and strong nails. The biotin-infused cake is carefully crafted using premium ingredients, ensuring a heavenly texture and taste that leaves you craving more. Treat yourself to our biotin-infused cake and let its deliciousness and nourishing benefits take you on a delightful journey of indulgence and self-care. Biotin, also known as vitamin H, is a water-soluble vitamin that is essential for the metabolism of carbohydrates, fats, and proteins. It acts as a coenzyme in various enzymatic reactions that are involved in energy production. By incorporating biotin into a cake, we can enjoy its benefits in a tasty and enjoyable way. One of the key benefits of biotin cake is its positive impact on our hair. Biotin helps strengthen the hair follicles, promoting healthy hair growth and preventing hair loss. It also

improves the texture and elasticity of the hair, making it more resilient to damage. So, while enjoying a slice of biotin cake, you're also giving your hair a little extra love and care.

INTRODUCTION

Biotin, also known as vitamin H, is a water-soluble B-vitamin that plays a crucial role in various metabolic processes in the human body. It is an essential nutrient required for the conversion of food into energy and the maintenance of healthy hair, skin, and nails. Biotin is involved in the metabolism of fatty acids, amino acids, and glucose. It serves as a cofactor for several enzymes that are important for these processes. This vitamin is particularly well-known for its ability to promote the health and appearance of hair, skin, and nails. Many beauty and hair care products contain biotin due to its potential to strengthen and improve the quality of these tissues. In addition to its beauty benefits, biotin supports overall health by contributing to normal immune function and playing a role in maintaining healthy eyes, liver, and nervous system. It is naturally found in a variety of foods such as eggs, nuts, seeds, and certain vegetables, but it is also available in supplement form for those who may need to increase their biotin Intake. Biotin deficiency is relatively rare, but when it occurs, it can lead to symptoms such as hair loss, skin rashes, and brittle nails. Biotin supplements are often used to address these issues or to support overall health and well-being.

SUNFLOWER SEEDS

Sunflower seeds are a natural source of biotin, making them a valuable dietary addition for maintaining strong and beautiful hair.

Fig 1: Sunflower Seed

OATS

Oats and oatmeal are not only good for our digestive system, but they are also high in biotin. One cup of cooked oats contains as much as 31 micrograms of biotin. It also offers other essential vitamins and nutrients such as zinc, magnesium, phosphorus and protein.

Fig 2: Oats

PEANUTS

Peanuts are an excellent source of biotin and help keep your nails stronger and hair longer. It also helps reduce the risk of colorectal cancer, gallbladder disease, and diabetes.

MATERIAL AND METHODS

COLLECTION OF RAW MATERIALS

SUNFLOWER SEEDS

Sunflower seeds are the fruits (achenes) of the sunflower (*Helianthus annuus* L.). The seeds are 10-15 mm long and 4 mm broad, cylindrical or drop-shaped. The sunflower seed consists of a hard hull (pericarp) and a kernel, which is the actual seed. Sunflower seeds are rich in oleic and linoleic acid and low in saturated fats and sodium. They also contain magnesium, potassium, and fiber. They help to lower blood pressure and serum cholesterol levels. Consuming them also reduces the occurrence of arrhythmias.

PEANUTS

Peanut, (*Arachis hypogaea*), also called groundnut, earthnut, or goober, legume of the pea family (*Fabaceae*), grown for its edible seeds. Native to tropical South America, the peanut was at an early time introduced to the Old-World tropics. The seeds are a nutritionally dense food, rich in protein and fat. Despite its several common names, the peanut is not a true nut.

BAKING SODA

Baking soda, also known as sodium bicarbonate or bicarbonate of soda, is a popular baking ingredient. It gives foods like bread, cakes, muffins, and cookies a light, fluffy texture. That's because it has leavening properties, meaning that it reacts with an acid, such as vinegar or lemon juice, and causes dough to rise by producing carbon dioxide. Still, baking soda has a variety of household uses aside from cooking.

BAKING POWDER

Baking powder is a mixture of baking soda and an acidic element called Cream of Tartar and corn flour. These are mixed in the dry state when they will not react together. However, when baking powder meets any liquid element, both these two react together to produce CO₂. Baking powder also continues to react with heat when the cake is baking in the oven. Since both alkaline and acidic elements are already present in baking soda, it can be used in recipes where no acidic ingredients are used.

BUTTER

In baking, butter adds flavor, softness, moisture to baked treats. It also helps baked goods rise and last longer. When it comes to baking any kind of pastries, cakes, cookies, or brownies, a quality stick of butter can really make all the difference. Butter helps make cakes and muffins softer and more tender. To achieve this effect, butter is creamed/emulsified with sugar until the mixture looks completely homogeneous, pale with a slight increase in volume.

VANILLA ESSENCE

Vanilla essence is made from vanilla beans that have been steeped in alcohol. It's widely used throughout the world to flavor desserts, like baked goods, ice cream, beverages, and custards, but some chefs use it as a secret ingredient savory dish as well.

WHEAT FLOUR

Wheat flour is a powder made from the grinding of wheat used for human consumption. Wheat varieties are called "soft" or "weak" if gluten content is low and are called "hard" or "strong" if they have high gluten content. Hard flour, or bread flour, is high in gluten, with 12% to 14% gluten content, and its dough has elastic toughness that holds its shape well once baked.

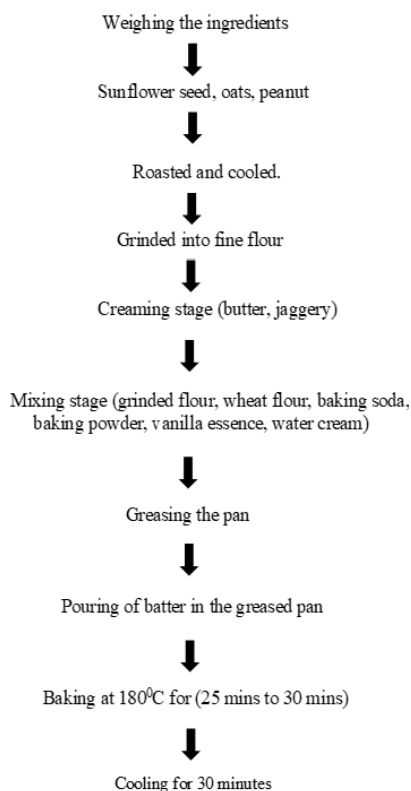

BROWN SUGAR

Brown sugar, also called table sugar, granulated sugar, or regular sugar, is a commonly used type of sugar, made either of beet sugar or cane sugar, which has undergone a refining process.

MILK

The purpose of milk in baking may depend on your recipe. Milk serves as a liquid medium your dry ingredients, dissolved sugar, and activate gluten, this not only improves the texture of your baked good, but also hydrates your protein and starches as well as your intervening agents, which initiates the chemical reactions that change the structure and texture of your dough Milk in cake recipes, generally makes the texture lighter and stronger Adding the right am keep the cake from being dense. Milk activates her ingredients in the cake batter like leaveners (baking soda, baking powder). And just the same as any other liquid in a cake recipe, it helps everything mix well and provides steam to help the cake rise.

METHODOLOGY

PREPARATION OF BIOTIN FLOUR

The collected raw materials like sunflower seeds, oats and peanuts are roasted. These biotin rich ingredients are allowed to cool and then grounded into a fine flour.

PREPARATION OF BATTER

Along with the biotin flour, other ingredients such as brown sugar, butter, wheat flour, baking soda, baking powder, milk and vanilla essence are added. These ingredients are properly mixed until it forms a smooth batter.

BAKING

The oven was allowed to be preheated for 5 minutes then the batter is poured into the pan and pan proofing was done for 30 minutes. Baking is done at 180°C for 20 minutes. Then the biotin cake was taken out of the oven and cooled for 30 minutes before serving.

ANALYSIS

SENSORY ANALYSIS

Sensory analysis examines the properties (texture, flavor, taste, appearance, smell, etc.) of a product or food through the senses (sight, smell, taste, touch and hearing) of the panelists. This type of analysis has been used for centuries for the purpose of accepting or rejecting food products. Traditional sensory techniques, such as discriminatory, descriptive evaluations, preference and hedonic tests, which are still widely used today, have evolved into newer, faster and more complete techniques: check-all-that-apply (CATA), napping (N), flash profile (FP), temporal dominance of sensations (TDS), etc., together with an important and adequate statistical analysis.

In our biotin cake sensory analysis were done by using hedonic scale. The most common hedonic scale is the nine-point hedonic scale ranging from 1= Dislike extremely and 9 = Like extremely. The hedonic scales assume that participants preferences exist on a continuum and that their responses can be categorized into like and dislike.

NUTRITIONAL ANALYSIS

Nutritional analysis is the process of determining the nutritional content of food. It is a vital part of analytical chemistry that provides information about the chemical composition, processing, quality control and contamination of food. It ensures compliance with trade and food laws.

CARBOHYDRATES

The nutritional analysis for carbohydrates in cake typically includes information on the total carbohydrates, which consist of sugars, fiber, and sometimes sugar alcohols. This breakdown helps consumers understand the source of carbohydrates in the cake. Total carbohydrates provide energy, while fiber contributes to digestive health. High sugar content may indicate a sweeter taste, while fiber content impacts digestion and satiety.

PROTEIN

The nutritional analysis of protein involves assessing various aspects such as protein content, amino acid profile, digestibility, and overall quality. Protein content is typically measured in grams per serving or per 100 grams of food, indicating the amount of protein present. Amino acid profile is crucial as proteins are made up of different amino acids, some of which are essential and must be obtained from the diet. Assessing the quality of protein involves considering factors like completeness (complete vs. incomplete proteins), digestibility, and bioavailability of amino acids. Analyzing protein sources requires understanding their nutrient composition, cooking methods that may affect digestibility, and considering individual dietary needs and goals for optimal nutrition.

FAT

Analyzing the nutritional content of fat in cake involves considering several factors that contribute to its overall composition and impact on health. Fats in cake primarily come from ingredients like butter, oil, eggs, and sometimes added fats in frosting or fillings. The nutritional analysis typically includes assessing the total fat content, including saturated, unsaturated, and trans fats. In addition to fat content, the nutritional analysis may also consider other nutrients like cholesterol and omega-3 fatty acids. Cholesterol levels in cake can vary depending on the use of whole eggs or egg whites. Omega-3 fatty acids, beneficial for heart health, may be present in cakes made with ingredients like walnuts or flaxseeds. It's important to note that while fats contribute to the flavor and texture of cakes, they should be consumed in moderation as part of a balanced diet. Choosing healthier fats, reducing saturated and trans fats, and opting for cakes with added nutritional elements like fruits, nuts, or whole grains can help improve the overall nutritional profile of cake products.

CONCLUSION

In conclusion, the addition of biotin to cake recipes not only elevates the taste but also contributes to promoting healthier hair, skin, and nails. This essential B-vitamin plays a crucial role in metabolic processes, making biotin-enriched cakes a thoughtful choice for those mindful of their nutritional intake. By incorporating biotin into our baking, we not only create delightful treats but also prioritize our well-being, making each slice of cake a small yet significant step towards a balanced and nourished lifestyle.

ABSTRACT

This study aims to develop a novel dietary fiber formulation derived from fruit seeds such as dates seed, mango seed, and jackfruit seed, focusing on its potential health benefits and applications in food products. Fruit seeds are often overlooked sources of valuable nutrients, including dietary fiber, which plays a crucial role in promoting digestive health and preventing various chronic diseases. The formulation process involves extraction, purification, and characterization of the dietary fiber from select fruit seeds, followed by incorporation into various food matrices. The resulting dietary fiber product exhibits favorable physicochemical properties, such as water-holding capacity, swelling capacity, and gel-forming ability. Moreover, its potential prebiotic effects are investigated through in vitro fermentation studies. The developed dietary fiber formulation shows promising results in enhancing the nutritional profile of food products while also contributing to gut health. Further research is warranted to explore the sensory aspects, stability, and consumer acceptance of dietary fiber-enriched food products.

KEYWORDS

Dietary fibre, Fruit seed, Preventing Chronic Disease

INTRODUCTION

Dietary fibre is defined in many different ways but most literature suggests that it is primarily a plant ingredient that is resistant to human digestion and absorption in the small intestine. Blackwood, A. D., et al., (2000) Nature has endowed various fruits with seeds, each packing a potent punch of dietary fibre. These seeds are highly effective in improving digestion supporting heart health etc. Dietary fibre from fruit seeds comes in two forms. Gabor Csatari et al., (2022) Insoluble fibre (IDF), Soluble fibre (SDF) dissolves in water, forming a gel-like substance that slows digestion regulates blood sugar levels, and aids in controlling cholesterol levels. Insoluble fibre on other hand, adds bulk to stool, promoting regular bowel movements and preventing constipation.

There are many products for diabetic's patient in the market but, it contains more carbohydrates and added sucrose for sweetness which is not good for health. Comparatively other product, our product contains less carbohydrate and adding date pulp for sweetness which contain glucose and fructose. The seeds of mango, dates, jackfruit are not only for adding delightful textures to your meals but also provide a host of health benefits. Discovers how dietary fibre from fruit seeds can positively impact your digestive health, support your heart, contribute to a balanced diet.

RAW MATERIALS

Jackfruit seed

Jackfruit seeds are rich in fibre and B-complex vitamins, aiding heart health, preventing constipation, and aiding weight loss. They also contain resistant starch for blood sugar regulation and gut health. We process them into powder by drying, grinding, and sieving.

Mango seed

Mango seeds have potent antioxidants and high-quality protein with essential amino acids. Including them in the diet may lower blood sugar and reduce

cardiovascular disease risk. We make powder by sun drying, grinding, and sieving collected seeds.

Date seed

Date seeds are rich in dietary content, aiding in kidney stone extraction and boosting immunity in pregnant women. They increase breast milk production and strengthen the immune system. Date seed powder, extracted from seeds collected at local grocery stores, is prepared by hot air oven drying, grinding, and sieving. It possesses antioxidant properties and protects the body's DNA structure

Date pulp powder

Date pulp powder, a natural sweetener, is made by drying and processing dates into coarse and fine-grain powders. It's an excellent sugar substitute rich in iron, dietary fibre, carbohydrates, proteins, antioxidants, calcium, and essential vitamins. It also contains phosphorus, niacin, and pyridoxine, with the highest antioxidant content among sugar alternatives.

Almonds

Almonds, originating from the Mediterranean, are actually drupe seeds. They're rich in nutrients like vitamin E, monounsaturated fats, fibre, biotin, and essential minerals such as calcium, phosphorus, magnesium, and copper. Almonds also contain phytonutrients, flavonoids, plant sterols, and phenolic acids.

Pistachios

Pistachios, from the cashew family, originated in Afghanistan, Central Asia, Syria, and Iran. They're rich in heart-healthy fatty acids, minerals, protein, and fiber. Their green and purple hues come from lutein and anthocyanin. Pistachios are abundant in potassium, copper, iron, magnesium, vitamin K, phytosterol, carotenoids, vitamin B6, and thiamine. They also boast antioxidant, anti-inflammatory, and anti-diabetic properties.

Cashew nut

Cashew trees, from South America's Anacardiaceae family, produce cashew seeds and apples. Cashew nuts are rich in protein, vitamins (E, B6, K), and minerals (carbohydrates, potassium, magnesium). They offer health benefits like antioxidants, anti-inflammatory, analgesic, anti-diabetic, antimicrobial, and cardio-protection

Roasted Bengal grams

Roasted Bengal grams or skinned grams, are packed with protein, fibre, vitamins, minerals, and fatty acids like calcium, manganese, copper, iron, and phosphorus.

Black chickpeas

Black chickpeas, or desi channa, native to India, are rich in protein, fibre, and carbohydrates. They're packed with vitamins B6, C, folate, niacin, thiamine, riboflavin, and minerals like manganese, phosphorus, iron, and copper. Kala Chana offers health benefits such as immune boosting, muscle mass promotion, and diabetes regulation.

Green gram

Green gram, or sprouted moong, is rich in essential nutrients like protein, fibre, vitamins, and minerals. Low in calories and fat, it's a great addition to a balanced diet. Green gram is also high in antioxidants, protecting the body from oxidative stress caused by free radicals

Barley

Barley (*Hordeum vulgare*), originating in the Middle East, is globally grown and rich in fibre, vitamins, minerals, and beta-glucan for cholesterol and blood sugar control. It provides essential minerals like manganese, selenium, phosphorus, copper, and B vitamins. With its nutty flavor and chewy texture, it's a versatile ingredient in various dishes, boosting both nutrition and taste.

Red rice

Red rice, a whole grain rice with a red husk, is packed with fibre, vitamins, minerals, and antioxidants. It promotes heart health, blood sugar control, digestive

health, and weight management. With a nuttier flavor and chewier texture than white rice, it's versatile in various dishes.

Groundnut

Groundnut, or peanut, a popular legume, rich in flavor and nutrients, originates from South America but is grown worldwide. It's high in protein, healthy fats, vitamins, and minerals like folate, niacin, magnesium, and phosphorus. Groundnuts can be eaten raw, roasted, or used in dishes and products such as peanut butter and oil.

Cardamom

Cardamom, an aromatic seed pod spice, originates from Kerala, India, belonging to the Zingiberaceae family with two genera, Elettaria and Amomum. Renowned for its aroma and flavor, it's rich in nutrients like protein, vitamins C and A, niacin, and riboflavin. It's also a valuable source of calcium, potassium, magnesium, and essential electrolytes.

METHODOLOGY

Collection of raw materials (mango seed, jackfruit seed, date seed)

Washing and cutting into small pieces

Placing in aluminium foil & kept in a hot air oven at 60 °c for 24hrs

Blend the dried seeds into powder

Sieving the powder gently using a seiver

Adding flavour enhancer and dates pulp powder based on the composition

Dietary fibre powder is accomplished

CHARACTERIZATION

Analysis of Macro-nutrients

Analysis of Proteins

Protein content was determined according to the method of (Lowry et al., 1957; AOAC, 2006). 1 ml of sample was mixed with 0.5 ml of 0.1 N NaOH and 5 ml of alkaline copper reagent, and incubated the mixture in room temperature for 30 minutes. Added 0.5 ml of Folin-Ciocalteu reagent and incubated again for 10 minutes at room temperature. Absorbance was read at 660 nm against a reagent blank. The analysis was performed in triplicates and the results were expressed g/100g sample.

Analysis of Carbohydrates

The total carbohydrate content was determined according to the method of Dubois et al., 1956; AOAC, 2006. 1.0 ml of sample was mixed with 1.0 ml phenol solution and added 5.0 ml of 96% sulphuric acid to each tube and shake well. Incubated in boiling water bath for 20 minutes, after which the absorbance was read at 490 nm against a reagent blank. The analysis was performed in triplicates and the results were expressed as mg/g sample.

Analysis of Fat

Crude fat was determined by ether extract method using Soxhlet apparatus where powdered sample (1 g) was wrapped in filter paper, placed in a fat-free thimble and then added to the extraction tube. The weighed, cleaned and dried receiving beaker was filled with petroleum ether and fitted into the apparatus and then water and heater were turned on to start the extraction. After 6 rounds of siphoning, ether was allowed to evaporate and the beaker was disconnected before the last siphoning. The extract was then transferred into a clean glass dish where the ether was washed and evaporated on the water bath. The dish was then placed in an oven at 105°C for 2 hrs and cooled. Then, the sample was allowed to cool in a desiccator and weighed (W1). The sample crucibles were ashed in a muffle furnace at 550°C for 4 h. The analysis was performed in triplicates and the results were expressed g/100g sample.

Analysis of Crude Fibre

This was done on the moisture-free, ether-extracted powdered sample where 0.2 g of the sample was weighed (W0) and transferred to a porous crucible with the crucible then placed into a Dosi- Fibre Unit with the valve kept in the 'OFF' position. After that, 150 mL of preheated H₂SO₄ solution was added and some drops of acetone (foam suppresser) were added to each column. Then, the cooling circuit was opened and the heating elements turned on (power at 90%). When it started boiling, the power was reduced to 30% and left for 30 min. Valves were opened for drainage of acid and rinsed with distilled water thrice to completely ensure the removal of acid from the sample. The same procedure was used for alkali digestion by using KOH instead of H₂SO₄. The sample was dried in an oven at 105°C for 1 hrs until a constant weight was attained. The analysis was performed in triplicates and the results were expressed g/100g sample

Analysis of Anti-oxidant property

The free radical scavenging activity of samples was measured by using 2, 2-diphenyl-1-picrylhydrazyl (DPPH) The scavenging activity for DPPH free radicals

was measured according to the procedure described by (Braca et al., 2001). An aliquot of 3 ml of 0.004% DPPH solution in methanol and 10 to 100 µl of plant extract/ascorbic acid at various concentrations were mixed. The mixture was shaken vigorously and allowed to reach a steady state at room temperature for 30 min. The decolorization of DPPH was determined by measuring the absorbance at 517 nm. A control was prepared using 0.1 ml of the respective vehicle in place of plant extract/ascorbic acid. The percentage inhibition of DPPH radicals by the extract/compound was determined by comparing the absorbance values of the control and the experimental tubes.

Scavenging activity %,

$$(\%) = \frac{A518 (\text{control}) - A518 (\text{sample})}{A518 (\text{control})} \times 100$$

Analysis of Anti-microbial activity.

Stock cultures were maintained at 4° C on slopes of nutrient agar and potato dextrose agar. Active cultures for experiments were prepared by transferring a loop full of cells from stock cultures to test tubes of 50ml nutrient broth bacterial cultures were incubated with agitation for 24 hours and at 37°c on a shaking incubator and fungal cultures were incubated at 27°c for 3-5 days. Each suspension of the test organism was subsequently stroked out on nutrient agar media and potato dextrose agar. Bacterial cultures were then incubated at 37°c for 24 hours and fungal incubated at 27°c for 3-5 days. A single colony was transferred to nutrient agar media slants were incubated at 37°c for 24 hours and potato dextrose slants were incubated at 27°c for 3-5 days. These stock cultures were kept at 4°c. For use in experiments, a loop of each test organism was transferred into 50ml nutrient broth and incubated separately at 37°c for 18-20 hours for bacterial culture.

RESULTS AND DISCUSSIONS

Analysis of Macro-nutrients:

S. No	Name of the Minerals	10 g/mg
1.	Glucose	1.5 g
2.	Proteins	1.8 g
3.	Fat	Not detect
4	Crude Fiber	3.8 g
5.	Copper	28 µg
6.	Sodium (Na)	22 µg
7.	Potassium	18 µg
8.	iron	58 µg
9.	zinc	90 µg
10.	Magnesium	0.95 µg
11.	Calcium	110 mg

Based on our analysis, confirmed that the product contains the precise composition of micro-nutrients in specific quantities.

Analysis of Anti-oxidant property

Concentration	% of Inhibition Ascorbic acid	Dietary fibre
20 g	34.91 %	30.10 %
40 µg	45.61 %	42.20 %
60 µg	68.82 %	60.00 %
80 µg	74.34 %	71.50 %
100 µg	89.23 %	82.10 %

From the analysis, it inferred that the 100ug concentration shows 82% of anti-oxidant properties

Analysis of Anti-microbial property

Organisms Concentration	<i>E. Coli</i>	<i>Strephylococcus aureus</i>
25 µl	0.2 cm	0.1cm
50 µl	0.3 cm	0.2 cm
75 µl	0.4 cm	0.3 cm
100 µl	0.5 cm	0.4 cm
Standard	0.8 cm	0.5 cm

The given sample shows antimicrobial activity against the Gram positive and Gram-negative bacteria.

From the analysis, The standard concentration of E.coli exhibited 0.8cm of microbial growth, whereas Streptococcus aureus showed 0.5cm of microbial growth.

Each concentration corresponds to a specific amount of microbial growth based on the organisms present.

CONCLUSIONS

In conclusion, the development of dietary fiber powder utilizing a combination of fruit seeds such as jackfruit, mango, and dates seeds, along with date pulp as a natural sweetener, presents an innovative approach to enhance nutritional intake. Moreover, the inclusion of almond, pistachio, cashew nut, red rice, groundnut, barley, green gram, black chickpeas, roasted Bengal gram, and cardamom adds not only to the fiber content but also to the diverse array of nutrients and flavors. This comprehensive blend offers potential health benefits, including improved digestive health, cholesterol regulation, and sustained energy release. Further research and development are essential to optimize the formulation for both efficacy and palatability, ensuring its acceptance and adoption as a convenient and nutritious dietary supplement.

ABSTRACT

Consumer Behavior compels manufacturers to innovate, altering production methods and ingredient compositions of familiar products. Investigating the potential of chocolate as a vehicle for beneficial, functional ingredients, this study pursued the development of a novel chocolate. The method involved careful dosing of functional ingredients, assuring consumption levels comparable to physiological norms. The essential target of this study was to formulate and evaluate natural nutritious chocolate. The process consisted of various stages of both primary and functional ingredients into the fundamental chocolate recipe. The inclusion of millets in the chocolate formulation aimed to increase the content of complete protein. Simultaneously, the carbohydrate profile of the chocolate was enhanced. This inclusion not only boosted the nutritional value of the chocolate but also improved it with the characteristics of a functional food product. In conclusion, the deliberate introduction of physiologically functional ingredients in the formulation of chocolate significantly enhances its nutritional profile, thereby offering consumers a healthier, beneficial alternatives.

DEVELOPMENT OF TERTIARY PACK FROM AGRO WASTE EVENTUALLY – A CATTLE FEED

ABSTRACT

The art and science of enclosing and containing goods for usage, distribution, storage, preservation, and confinement is known as packaging. Virgin wood pulp can be used to make tertiary cardboard packs. A dopting virgin wood can be avoided from an environmental standpoint by adopting a substitute. Expanded use of wastepaper, non-wood fiber plants, increasing use of forest waste, and other environmental materials can all help meet the growing demand for woody supplies. On the other hand, in order to meet the growing demands of the rapidly expanding population, agricultural wastes are produced every day. 620 million tons of agricultural waste are produced in India each year. The management of agricultural waste can be used to produce energy and feed cattle. Creating an environmentally friendly, the goal of this project is to turn agricultural wastes, mostly natural fibers from rice husk, banana peel, and Saccharum offcinarum (sugarcane leaf), into an environmentally acceptable paperboard material. Consequently, less virgin wood pulping material will be needed, and paperboard will be used as cow feed. Cattle may be able to consume the agricultural waste used to make cardboard. The main ingredients used as cow feed are sugar cane leaf, rice husk, and banana peel, all of which make excellent diet feed. These materials serve as a good source of nourishment and are non-toxic to cattle. Its easy degradation, when not used as cattle feed, lowers the pollution caused by the materials used in packaging. Organic, biodegradable, agricultural wastes may reduce the environmental pollution.

Abstract

Kennel dogs and their movements have a growing figure of health problems. And in more recent times, dogs have assimilated into everyday human life. So, a ZigBee module-based system for tracking and monitoring pet dogs' health is created. The usage of ZigBee technology is expanding across a variability of application situations. Sensors like the temperature sensor, heart ratio sensor, beat degree sensor, and breathing sensor are used to observe the health of pet dogs.

To display the digital data, a Graphical User Interface (GUI) would be attached to the ZigBee module. We can practically link any gadget to the internet and apply the IOT concept thanks to the development of technology and the existence of the internet marketing and selling of this device in small limited market is challenging.

Introduction

In India, it is estimated that there are 25 million dogs, most of which are ownerless and unsupervised (Sudarshan MK, 2005). However, another 1 estimated figure of the stray dog population is 8-20 million (Otter, 2010). Population figures, thus, vary and there is no widely-accepted figure. WHO (1990) classifies dogs based on their level of dependence on humans for food, shelter and companionships, as well as the extent of supervision, Restricted or supervised dog (fully dependent and fully restricted), Family dog (fully dependent, semi-restricted), Neighbourhood dog (semi-dependent, semi-restricted or unrestricted), Feral dogs (independent, unrestricted).

In India 60% of the dog population falls under the neighbour hood dog category (Reece JF and Chawla SK, 2006) and 80% of the dog population in India falls under the last three categories (Menezes R, 2008). Neighbour hood dogs belong to the community as a whole. Such dogs are mostly unrestricted and poorly supervised, food may or may not be provided and shelter is almost always provided. These dogs are rarely vaccinated and health care provided to them is negligible. They safeguard the community and often provide companionship. Census of neighbour- hood dogs and pet dogs is randomly and unscientifically conducted in India. In a survey of 13 municipal corporations, only four had conducted dog census in the last 10 years.

The censuses also did not differentiate between pet and neighbour hood dogs (Federation of Indian Animal Protection Organizations, 2013, unpublished). In a survey of 8,500 households in India, both rural and urban, it was found that about 17% households had pet dogs and the pet dog: person ratio was 1:36 (Sudarshan MK, 2005). In a sample study of 30 clusters in Bangalore, it was estimated that the city had a total dog population of 3.25 lakhs out of which 2 lakhs (61.5%) were stray dogs and 1.25 lakhs (38.5%) were pet dogs. The dog person ratio was about 1:12 and the pet:stray dog ratio of 1:2.(Sudarshan MK et. al., 2001).

In this work, we have demonstrated a novel design objective of the one-to-one health care system for animals, namely, the ability to monitor heart rate, body temperature, and rumination in the presence of high relative humidity and temperature. Its topographies have high enactment, movability, energy efficiency, cognition, miniaturization, and fresh resources at lower costs.

The shortcomings of the current system will be shocked by the suggested approach. Heart rate sensor, temperature sensor, pulse rate sensor, and respirational sensor are four important measuring devices that are used. Also, if an animal goes missing or gets lost, a GPS (Global Positioning System) is set up to track its movements. Through the use of a ZigBee transceiver, data from the microcontroller is used and sent to a PC running software designed to analyze the severity of animal health issues. Afterwards, the same program can be accessed by various Internet of Things techniques.

Kennel Management

It is essential to maintain the dogs at an optimum level of health so that they are able to perform their duties efficiently. It is most important that no stagnant water or sewage is

allowed to collect inside the kennels or blocks. A proper system of ventilation must be adopted which while ensuring a constant change of air does not introduce draughts and proper circulation of fresh air is ensured.

Kennels Hygiene

Kennels should be thoroughly cleaned daily and all soiled bedding and excreta removed and burnt. Sleeping board should be scrubbed with soap and water once a week and due care taken so that they are completely dry before being returned to kennels.

Disinfecting of kennels

Whenever the presence of an infectious or contagious disease has been confirmed, or even suspected, thorough disinfections of the individual kennel concerned or the whole kennel block, if disease is wide spread, must be vigorously carried out.

Tick Control

Control of ticks is of vital importance. Ticks are blood-sucking parasites, which attach themselves to the skin for varying periods of time.

Temperature Control of Kennels:

- Management in hot areas: Management of kennels in hot areas is very important. Depending upon the local temperature and weather conditions like humidity, option of air coolers /air conditioners for regulating the kennel temperature must be considered.
- Management in cold area: Management of dogs in extreme cold environments do not pose any special problems as they withstand the cold pretty well. Any form of artificial heating is quite unnecessary and its use should be confined solely to puppies and hospital kennels. It is of the utmost importance that, during training dogs are hardened to withstand the rigorous conditions of active service.

System overview

The suggested model is intended to be beneficial for all kennel owners and veterinarians who can carefully watch animal health activities. Additionally, pet owners have the option of searching for missing pets.

The heart rate sensor, temperature sensor, pulse rate sensor, and respiration sensor are the four significant sensors shown in Figure 1. In the event that an animal goes missing or becomes lost, a GPS (Global Positioning System) is used to track its movements, something

that has not yet been suggested by any of the existing systems. ZigBee would be the wireless technology employed. ZigBee can support up to 64000 devices at a distance of 50 meter's and has a very low power consumption range of 10-3000 meter's.

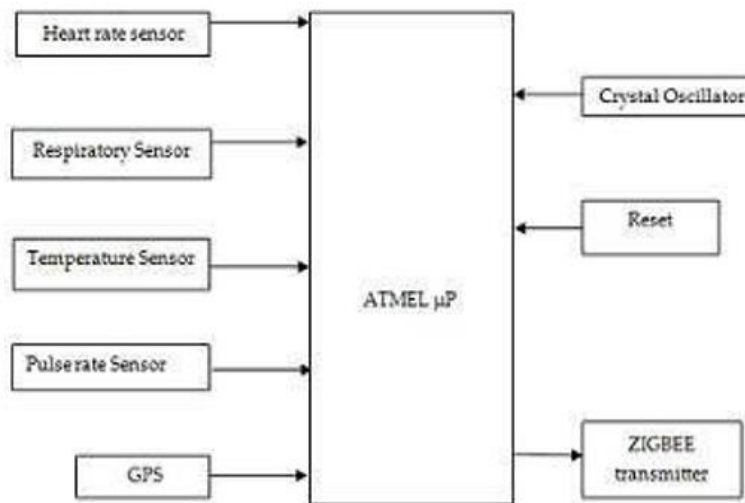

Figure 1: Block drawing of the transmitting end

Figure 2 shows how the records from the embedded microcontroller in the system are gathered by the ZigBee transceiver and sent to a PC via the UART protocol. The data may require editing because it is raw. In the upcoming phase, a software system will be created to analyze the data, though.

Figure 2: Block drawing of the receiving end

Figure 3 shows how a website will receive the hardware's data values to be processed. The website/ webpage will include analysis of each of the five data variables. After the data has been analyzed, we can determine if there is a threat to animal health based on a threshold (a dog's temperature should range from 37.9 to 39.9 degrees). For instance, a sudden rise in temperature after hours of observation can indicate that the animal may be contagious.

Additionally, medication suggestions are possible. If a serious condition develops, the regular doctor might be informed.

The system would be accessible on any IOT-enabled device in order to develop and adapt to modern trends. With the use of the IOT, users and owners will be able to check on their pets or other animals at anytime, anywhere. The data would be saved in the cloud because the data getting from the gadget is real-time and ongoing.

Figure 3: Block diagram of IOT implementation

Temperature Sensor Module

A domestic animal's core body temperature (CBT), which indicates body temperature, can be measured. Any difference from their typical temperature is considered abnormal. For instance, the body temperature of a domestic cow ranges from 38.0 to 39.3 degrees Celsius. While a dog's temperature ranges from 37.9 to 39.9 degrees. And any departure from these temperatures can alert us to a problem. Therefore, we use an LM35 temperature sensor to measure this. The operating temperature range for the LM35 is 55° to 150°C.

Heart rate measuring device Module

An alpha numeric output of the heartbeat is meant to be created when a finger is placed on a heartbeat sensor. When the heart beat detector is working, the beat LED lights in rhythm with each heartbeat. A microcontroller can be directly connected to this digital output in order to measure the taps per minute (TPM) rate. It functions on the principle that the amount of modulated light varies with each pulse.

Pulsation Rate Sensor Module

With the aid of some jumper wires, the sensor is attached to a fingertip or earlobe. It also comes with a free observing app that displays a real-time graph of your pulse. It simply syndicates a straight forward visual heart rate sensor with electronics for noise reduction and amplification, making it quick and simple to obtain accurate pulse readings. Over a minute, the pulse rate is calculated.

Breathing Sensor Module

The inflatable belt that hush-up around the chest and comparative pressure sensor are both parts of the respiration rate sensor. On a computer, a graph showing changes in breathing rate and pressure can be seen as the being breathes. The pressure sensor in the belt monitors the pressure inside its bladder when the lungs expand and contract when it is connected to the relative pressure sensor. Although the pressure measured does not accurately reflect the pressure change in the lungs, the density of the increasing chest cavity and lungs pushes against the bladder of the belt.

Global Positioning System

Positions on the planet can be found using the Global Positioning System (GPS), a satellite- based navigation system. It is composed of satellites, control and monitoring stations, and receivers and is created and run by the United States Department of Defense. To determine an animal's precise location, GPS devices employ triangulation to combine data received from satellites.

Zig Bee Transceiver

Based on the IEEE 802.15.4 standard, ZigBee is an enabling technology that offers low data rates, low battery consumption, and inexpensive costs. It makes a contribution to both the wireless sensor network and the wireless personal area network. ZigBee has the capacity to create a vast network; it can accommodate up to 64000 devices separated by 50 meters. It uses incredibly little Power

Internet of things

The network of actual physical objects—devices, cars, buildings, and other things with electronics, software, sensors, and network connectivity—that allows these things to gather and share data is known as the Internet of Things (IoT). Through the use of existing network infrastructure, IoT enables objects to be sensed and controlled remotely. This more direct

integration of the physical world and computer-based systems leads to increased effectiveness, accuracy, and financial gain.

Implementation

All four of the aforementioned sensors were used in the real-world implementation of the suggested animal health monitoring and tracking system. The UART protocol was used to transfer the sensor readings through the wireless ZigBee communication channel, and the putty program is used to display them on both the LCD and the computer. Consequently, it is shown that the data acquired is accurate and that it is possible to integrate GPS and sensors into a single microcontroller without interference. But only when the model is moving does the GPS work. Furthermore, earlier models were unable to attain the accuracy and precision that this model does. A figure that shows how it was done is attached.

Marketing of IoT ZigBee Device to Kennels

According to Researcher observation & Interactions with Dog Kennels Owners:

- Analyzing customer buying habits across Kennels Owners Platforms it's a linked with one another
- Gathering previously unobtainable data about how consumers interact with devices and products from Different Kennel Owners
- Gaining deeper insights into where a customer is in the buying journey any new updates he is looking from the Device etc information's will be collected from Kennel owners to keep upgrading the Device.
- Providing real-time, point-of-sale notifications and targeted ads and many more services will also be added according to more orders Received from Kennel Owners. Quickly resolving issues to close sales and keep customers happy.

IOT's benefits depend on its particular implementation. It means smarter, more measurable systems that can help marketers in a number of different ways.

Conclusion

The fundamental concept of this article is to combine two already-developed modules that were created using various platforms and technologies into a solitary component and platform. The four various sensors and the GP module can work together to function in an embedded system. The microcontroller, which employs categorical ADC to provide the correct details in cases of health observing and position tracking, is responsible for the values' accuracy. In this research paper researcher also discussed about how this IoT device will also be marketed in this Limited Market to retain the Kennel owners and develop good networks to retain for a qualitative services for long term. This model will serve as a solid foundation for any analysis of animal health-related problems. Future work on this paper will focus on improving the wearable device's hardware so that it can be linked to any other device via the internet of things. But because the wearable technology poses a significant security risk researcher is involved in investigating and working on new updated technologies.

Abstract

This paper investigates the application of Internet of Things (IoT) technology in the domain of water management to enhance efficiency and sustainability. Traditional water management systems often suffer from limitations such as inaccurate monitoring, inefficient distribution, and inadequate response to leaks. Leveraging IoT devices, sensors, and communication networks, this study proposes a comprehensive framework for smart water management. By deploying sensors to collect real-time data on water quality, consumption patterns, and infrastructure conditions, the system enables proactive monitoring and control. Through advanced analytics and remote actuation, anomalies such as leaks can be swiftly detected and addressed, leading to optimized resource allocation and reduced wastage. The integration of IoT facilitates a holistic approach to water management, enabling stakeholders to make informed decisions and promote responsible water usage practices. This abstract provides a succinct overview of the methodology, functionalities, and potential advantages of implementing IoT in water management systems, highlighting its significance in addressing the challenges of water scarcity and sustainability.

INTRODUCTION

Water scarcity and inefficient water management have become pressing issues globally, necessitating innovative solutions to ensure sustainable use of this essential resource. Traditional water management methods often lack real-time monitoring and control capabilities, leading to wastage, leaks, and environmental degradation. In response to these

challenges, the integration of Internet of Things (IoT) technology offers a transformative approach to water management. The application of IoT in the realm of water management, aiming to enhance efficiency, conservation, and sustainability. By deploying IoT devices such as sensors, actuators, and communication networks, a smart water management system can be established to monitor, analyze, and optimize water usage in real time. Through continuous data collection and analysis, anomalies such as leaks or fluctuations in water quality can be swiftly detected and addressed, enabling proactive measures to mitigate losses and ensure efficient distribution. IoT-driven smart water management solutions hold the potential to revolutionize the way we manage and conserve water resources, ultimately contributing to a more sustainable and resilient future.

PROBLEMS &SOLUTIONS

Problems:

- Traditional water management systems lack real-time monitoring capabilities, leading to inefficient resource allocation and response to water-related emergencies.
- Limited visibility into water usage patterns makes it challenging to identify leaks, detect contamination events, and optimize water distribution networks.
- Increasing water scarcity and pollution exacerbate the need for more effective and sustainable water management practices.
- Manual processes for data collection and analysis are time-consuming and prone to errors, hindering timely decision-making and proactive interventions.

IoT Solutions:

- Integration of IoT technology enables real-time monitoring of water systems through the deployment of sensors across infrastructure.
- IoT devices collect data on parameters such as water flow, quality, pressure, and temperature, providing comprehensive insights into water usage and infrastructure health.
- Centralized platforms utilize advanced algorithms and analytics to process and analyze the data, enabling proactive identification of anomalies and optimization of water distribution networks.

- Automated anomaly detection and response mechanisms facilitate rapid intervention in the event of leaks, contamination events, or abnormal consumption patterns.
- By leveraging IoT-enabled smart water management systems, stakeholders can make data-driven decisions to optimize resource allocation, reduce water losses, and enhance overall system efficiency and sustainability.

The solution promotes transparency, public engagement, and collaboration among stakeholders, fostering a more resilient and adaptive approach to water management in the face of evolving challenges such as climate change and population growth.

METHODOLOGY

Objectives and Requirement : Clearly define the objectives of the smart water management system, such as reducing water wastage, optimizing water usage, and ensuring water quality. Identify the specific requirements of the system, including the types of sensors needed, data collection frequency, and desired outcomes.

Survey and Assessment: Conduct a survey and assessment of the water system to identify key points for sensor deployment. This could include water sources, distribution networks, storage facilities, and consumption points. Assess the existing infrastructure and identify areas for improvement.

Sensor Selection and Deployment: Select appropriate sensors based on the objectives and requirements defined earlier. Deploy sensors at strategic locations to monitor parameters such as water level, flow rate, pressure, and quality. Ensure that sensors are properly calibrated and configured for accurate data collection.

IoT Device Implementation: Implement IoT devices such as microcontrollers, gateways, and communication modules to gather data from sensors and transmit it to a central system. Choose communication protocols and technologies that are suitable for the environment, such as Wi-Fi, cellular, or LPWAN.

Cloud Platform Setup: Set up a cloud-based platform to collect, store, and analyse the data gathered from sensors. Choose a platform that supports real-time data processing, analytics, and visualization. Configure data pipelines and storage systems to handle large volumes of data efficiently.

Data Analytics and Insights: Develop algorithms and models to analyze the data collected from sensors. Use techniques such as machine learning for predictive maintenance, anomaly detection, and optimization of water usage.making and water management strategies.

User Interface Development: Design and develop a user interface, such as a web-based dashboard or a mobile application, to visualize water usage data, receive alerts, and control water management systems remotely. Ensure that the interface is user-friendly and provides relevant information to stakeholders.

Integration and Testing: Integrate all components of the smart water management system and conduct thorough testing to ensure functionality, reliability, and scalability. Test the system under various conditions and scenarios to identify any potential issues or bottlenecks.

Deployment and Monitoring: Deploy the smart water management system in the field and monitor its performance in real-world conditions. Continuously monitor data quality, system uptime, and user feedback to identify areas for improvement and optimization.

Maintenance and Updates: Establish a maintenance schedule to ensure the proper functioning of the system over time. Perform regular updates and upgrades to software and hardware components to address security vulnerabilities and incorporate new features and technologies.

This methodology, you can effectively implement a smart water management system using IoT to optimize water usage, reduce wastage, and improve overall efficiency and sustainability.

FUNCTIONALITIES

Leak Detection: IoT sensors can detect leaks in real-time, allowing for prompt repairs and reducing water wastage.

Remote Monitoring: Users can monitor water usage and system performance remotely through a mobile app or web interface.

Automated Irrigation: IoT devices can adjust irrigation schedules based on weather forecasts, soil moisture levels, and plant requirements, ensuring optimal water usage for landscaping and agriculture.

Water Quality Monitoring: Sensors can monitor water quality parameters such as pH, turbidity, and contaminants, alerting users to any potential issues and ensuring water safety.

Predictive Maintenance: By analyzing data from sensors, predictive maintenance algorithms can anticipate equipment failures and schedule maintenance proactively, minimizing downtime and conserving water.

Demand Response: Smart systems can adjust water usage based on demand patterns, helping utilities manage peak loads and optimize resource allocation.

User Feedback and Education: Providing users with real-time feedback on their water usage habits can encourage conservation and promote sustainable behavior.

Integration with Other Systems: Integration with weather forecasting systems, utility networks, and smart home platforms can enhance functionality and interoperability.

These functionalities collectively enable efficient water management, conservation, and sustainability through the use of IoT technology.

ADVANTAGES

Real time monitoring: Provides real-time insights into water usage, allowing for immediate detection and response to leaks, abnormal usage patterns, or other issues.

Efficient resource allocation: Enables optimized allocation of water resources based on demand, usage patterns, and environmental conditions, leading to reduced wastage and improved efficiency.

Cost savings: By identifying and addressing inefficiencies, such as leaks or over-irrigation, smart water management systems can help reduce water bills and operational costs.

Conservation: Promotes water conservation through automated controls, smart scheduling, and user feedback, encouraging more responsible water usage behaviors.

Improved Infrastructure Management : Enables predictive maintenance and proactive management of water infrastructure, reducing the risk of costly repairs and downtime.

Environmental sustainability: By reducing water wastage and improving efficiency, smart water management contributes to environmental sustainability and conservation of water resources.

Enhanced data driven decision making: Provides valuable data and insights for informed decision-making, allowing stakeholders to implement targeted interventions and optimizations.

Scalability and Flexibility: IoT-based solutions can be scaled and adapted to various settings, from residential homes to large-scale agricultural operations or municipal water systems.

FUTURE OUTLOOK

Expansion of IOT Adoption: The adoption of IoT technology in water management will continue to expand across various sectors, including agriculture, utilities, industrial facilities, and smart cities. This growth will be driven by increasing awareness of water scarcity, regulatory pressures, and the need for efficiency gains.

Integration with Emerging Technologies: IoT in water management will increasingly integrate with other emerging technologies such as artificial intelligence, machine learning, blockchain, and edge computing. These technologies will enhance data analytics, automation, and decision-making capabilities, leading to more efficient water management practices.

Advancement in sensor technology: Continued advancements in sensor technology will lead to the development of more cost-effective, durable, and accurate sensors for monitoring water quality, quantity, and infrastructure conditions. Miniaturization and improvements in battery life will further enable the deployment of sensors in remote or harsh environments.

Real time monitoring and predictive analytics: IoT-enabled sensors and monitoring devices will provide real-time data on water usage, quality, and infrastructure health. This data will be leveraged for predictive analytics, allowing stakeholders to anticipate issues such as leaks, contamination events, or equipment failures before they occur.

Smart water distribution network: IoT technology will facilitate the development of smart water distribution networks that can dynamically adjust water flow, pressure, and distribution based on real-time demand, supply, and infrastructure conditions. This will minimize water losses, reduce energy consumption, and optimize resource allocation.

Resilience to Climate Change and Extreme Events: IoT technology will play a crucial role in building resilience to climate change impacts and extreme weather events such as floods, droughts, and storms. Real-time monitoring, early warning systems, and adaptive management strategies will help mitigate risks and ensure the reliability and sustainability of water supplies.

The future of IoT in water management holds great potential for improving water efficiency, enhancing resilience, and ensuring the sustainable use of this critical resource. Continued innovation, investment, and collaboration will be essential to realizing these benefits and addressing the complex water challenges facing society.

SOFTWARE & PROGRAMMING

IoT Platforms :

AWS IoT: Amazon Web Services provides a comprehensive IoT platform with services for device management, data ingestion, analytics, and integration with other AWS services.

Microsoft Azure IoT: Azure IoT offers a range of services for building and managing IoT solutions, including device provisioning, data processing, and machine learning capabilities.

Google Cloud IoT: Google Cloud Platform provides IoT Core for device connectivity, Cloud IoT Edge for edge computing, and Dataflow for data processing and analytics.

Programming Language :

Python: Python is widely used for IoT development due to its simplicity, versatility, and extensive libraries for data processing, machine learning, and cloud integration.

JavaScript : Node.js is commonly used for server-side scripting and developing IoT applications that run on edge devices or communicate with cloud platforms.

C/C++: C and C++ are preferred for programming embedded systems and microcontrollers commonly used in IoT devices due to their efficiency and low-level control.

Java: Java is used for developing backend services, middleware, and enterprise applications that interact with IoT devices and manage data processing tasks.

CONCLUSION

The application of Internet of Things (IoT) technology in water management presents a compelling solution to the challenges of inefficient resource allocation, water wastage, and

environmental degradation. By leveraging IoT devices, sensors, and advanced analytics, smart water management systems enable real-time monitoring, proactive intervention, and data-driven decision-making.

Through the deployment of sensors to collect real-time data on water quality, consumption patterns, and infrastructure conditions, stakeholders can gain comprehensive insights into water usage and system health. Automated anomaly detection and response mechanisms allow for swift identification and mitigation of issues such as leaks or contamination events, leading to optimized resource allocation and reduced wastage.

The integration of IoT facilitates a holistic approach to water management, promoting transparency, public engagement, and collaboration among stakeholders. By embracing IoT-enabled smart water management systems, we can work towards ensuring the sustainable use of this critical resource, ultimately contributing to a more resilient and environmentally sustainable future. Continued innovation, investment, and collaboration will be crucial in realizing the full potential of IoT in addressing the complex water challenges facing society.

Abstract

Smart mirrors represent an innovative integration of technology into everyday objects, offering a blend of functionality and style that transforms traditional mirrors into interactive and personalized devices. This abstract delves into the concept, design, and potential applications of smart mirrors. Beginning with an exploration of their underlying technology, including embedded displays, sensors, and connectivity options, the abstract highlights the diverse features and capabilities that smart mirrors offer, such as weather updates, fitness tracking, virtual styling, and home automation integration. Moreover, it discusses the benefits of smart mirrors in enhancing user experience, promoting efficiency, and facilitating seamless interaction with digital content in various settings, including homes, retail stores, and hospitality venues. Additionally, the abstract addresses considerations such as privacy, security, and user interface design in the development and deployment of smart mirrors. Lastly, it examines emerging trends and future prospects for smart mirror technology, underscoring its potential to redefine the way individuals engage with mirrors and access information in the modern digital age.

INTRODUCTION

In recent years, the convergence of technology and everyday objects has led to the emergence of innovative solutions aimed at enriching human experiences. Among these, smart mirrors have garnered significant attention for their potential to seamlessly integrate digital functionality into a traditionally analog fixture of daily life. With the ability to display information, provide personalized feedback, and enhance user interaction, smart mirrors represent a promising avenue for addressing contemporary challenges and improving the quality of life. This introduction provides an overview of the concept of smart mirrors, their underlying technology, and their diverse applications across various domains. Additionally, it discusses the relevance of smart mirrors within the IEEE community and outlines the scope of this paper in exploring their design principles, implementation challenges, and future directions. Through a comprehensive examination of smart mirror technology, this paper aims to shed light on its transformative impact on daily routines, societal interactions, and technological advancements, thereby contributing to the growing body of research in the field of ubiquitous computing and human-computer interaction.

METHODOLOGY

Hardware Selection and Integration: This initial phase involves selecting appropriate hardware components such as displays, sensors (e.g., motion sensors, cameras), microcontrollers, and connectivity modules. Methodologies include assessing technical requirements, compatibility, and form factor considerations to integrate these components seamlessly into the mirror structure.

Software Architecture Design: Designing the software architecture involves defining the overall structure of the smart mirror system, including software modules, data flow, and communication protocols. Methodologies such as modular design, service-oriented architecture (SOA), or event-driven architecture (EDA) are commonly used to ensure scalability, maintainability, and flexibility.

User Interface (UI) and User Experience (UX) Design: UI/UX design methodologies focus on creating intuitive, visually appealing interfaces that enhance user engagement and satisfaction. This includes conducting user research, creating wireframes or mockups, and

iteratively refining the design based on user feedback. Human-centered design (HCD), usability testing, and iterative prototyping are key methodologies in this phase.

Interaction Design: Interaction design methodologies involve defining how users interact with the smart mirror, including input modalities (e.g., touch, voice, gesture), feedback mechanisms, and response times. This may include employing techniques such as user scenario mapping, task analysis, and designing affordances to guide user interactions effectively.

Software Development: Software development methodologies such as agile, iterative, or waterfall are applied to implement the software components of the smart mirror system. This includes writing code for features like display management, data processing, user input handling, and integration with external services or APIs.

Integration with External Systems: Smart mirrors often need to integrate with external systems or services to provide additional functionality or access external data sources. Methodologies for integration include API usage, data synchronization, authentication, and error handling to ensure seamless communication with external systems.

Testing and Quality Assurance: Testing methodologies are crucial for ensuring the reliability, performance, and usability of smart mirrors. This includes unit testing of individual software components, integration testing of hardware and software systems, and user acceptance testing (UAT) to validate the overall functionality and user experience.

Deployment and Maintenance: Methodologies for deployment involve preparing the smart mirror system for production environments, including installation, configuration, and user training. Maintenance methodologies focus on ongoing support, updates, and troubleshooting to ensure the continued functionality and performance of the smart mirror over time.

FUNCTIONALITIES

A smart mirror is a technologically enhanced mirror that displays information such as time, weather, calendar events, news updates, and more on its surface. It typically consists of a two-way mirror with a transparent display panel behind it. When the display is turned on, the information is superimposed on the reflection of the mirror, creating an interactive and informative display.

Smart mirrors often come equipped with various features such as voice control, touch interactions, and the ability to connect to the internet to access real-time data. They can be customized to display different types of information based on the user's preferences or needs. Some smart mirrors also have additional functionalities like integrating with smart home devices, playing music, displaying fitness data, and more.

The functioning of a smart mirror involves the use of sensors, microprocessors, displays, and software to provide a seamless user experience. Users can interact with the mirror to access information, control connected devices, and perform various tasks without the need for additional screens or devices. Smart mirrors are commonly used in homes, hotels, retail stores, and other commercial spaces to provide both utility and a futuristic touch to traditional mirrors.

FUTURE SCOPE

Augmented Reality Integration: Smart mirrors can be enhanced with augmented reality (AR) technology to provide real-time interactive experiences. This could involve virtual try-on for clothing and accessories, makeup tutorials, or even fitness coaching with real-time feedback.

Health Monitoring: Smart mirrors could be equipped with sensors to monitor health parameters like heart rate, blood pressure, and body fat percentage. This information could be displayed directly on the mirror or synced with an app for tracking and analysis.

Personalized Content: Using facial recognition technology, smart mirrors can display personalized content such as news updates, calendar events, weather forecasts, and tailored recommendations based on the user's preferences.

Home Automation Control: Smart mirrors can serve as a central hub for controlling smart home devices like lights, thermostats, security cameras, and music systems. Users can conveniently manage their home automation systems through voice commands or touch gestures.

Virtual Assistant Integration: Integrating virtual assistants like Amazon Alexa, Google Assistant, or Siri into smart mirrors can enable users to access information, set reminders, make calls, and perform various tasks hands-free while getting ready in front of the mirror.

Interactive Fitness and Wellness: Smart mirrors can offer interactive fitness classes, yoga sessions, and workout routines guided by virtual instructors. They can also provide feedback on posture and technique to help users improve their fitness goals.

Enhanced Personalization: Future smart mirrors may offer advanced customization options, allowing users to change the mirror's appearance, lighting effects, background themes, and more to suit their preferences and mood.

Retail and Advertising Applications: Smart mirrors in retail stores can provide customers with personalized product recommendations, virtual try-on experiences, and interactive shopping features. Advertisers can also utilize smart mirrors for targeted advertising campaigns based on user demographics and preferences.

Environmental Sensors: Smart mirrors equipped with environmental sensors can provide information on air quality, temperature, humidity levels, and even suggest lifestyle changes for a healthier living environment.

Security Features: Smart mirrors can incorporate security features like facial recognition for user authentication, emergency alerts, and integration with home security systems to enhance safety and privacy.

SOURCE CODES

JavaScript: JavaScript is often used for developing the user interface and interactive features of smart mirrors. Frameworks like React or Angular may be employed to create dynamic and responsive interfaces.

Python: Python is frequently used for backend development and data processing tasks in smart mirrors. It's well-suited for tasks such as data retrieval, analysis, and integration with external APIs or services.

C/C++: These languages are commonly used for low-level programming tasks, particularly when working with embedded systems or hardware components in smart mirrors. They may be used for interfacing with sensors, controlling displays, or optimizing performance.

HTML/CSS: HTML and CSS are used for structuring and styling the user interface of smart mirrors. They define the layout, appearance, and visual elements displayed on the mirror's screen.

Java/Kotlin: For Android-based smart mirrors, Java or Kotlin may be used for developing native applications or integrating with Android-specific APIs and functionalities.

Swift/Objective-C: For iOS-based smart mirrors, Swift or Objective-C may be used for developing native applications or integrating with iOS-specific APIs and functionalities.

SQL: SQL (Structured Query Language) may be used for managing and querying databases that store user preferences, settings, or historical data related to smart mirror usage.

Shell Scripting: Shell scripting languages like Bash may be used for automating tasks, managing system configurations, or performing maintenance tasks on the smart mirror's operating system.

SOFTWARES

Operating System: Smart mirrors often run on embedded operating systems optimized for resource-constrained devices. Examples include:

****Raspberry Pi OS (formerly Raspbian):** A Debian-based Linux distribution optimized for Raspberry Pi single-board computers, commonly used for DIY smart mirror projects.

****Android:** Some smart mirrors use Android as their operating system, particularly those with touchscreen displays or advanced interactive features.

****Windows IoT Core:** Microsoft's lightweight operating system designed for IoT devices, suitable for smart mirrors running on Windows-compatible hardware.

Display Software: Software is needed to manage the display output on the mirror's screen. This may include:

****Magic Mirror²:** A popular open-source platform for creating customizable smart mirror interfaces using HTML, CSS, and JavaScript.

****Dakboard:** Another customizable dashboard software for smart mirrors, offering features like calendar integration, weather updates, and news feeds.

Custom Applications: Smart mirrors may run custom applications or software modules to provide specific functionalities. These applications can be developed using various programming languages and frameworks, depending on the requirements of the project.

Communication and Connectivity: Smart mirrors may utilize software for communication and connectivity with other devices and services. This may include:

****Web Browsers:** Smart mirrors often include web browsers to access online content, services, and APIs.

****Networking Software:** Software for managing network connections, such as Wi-Fi or Bluetooth, is essential for smart mirrors with connectivity features.

****API Integration:** Software modules or scripts may be used to integrate with external APIs for fetching data, such as weather forecasts, news updates, or calendar events.

Security Software: Security software may be employed to protect smart mirrors from potential threats and vulnerabilities. This may include:

****Firewall Software:** Firewalls can help prevent unauthorized access to the smart mirror's operating system and network interfaces.

****Antivirus/Antimalware Software:** Antivirus or antimalware software can detect and remove malicious software that may compromise the security of the smart mirror.

Content Management Systems (CMS): Some smart mirrors utilize content management systems to manage and display content dynamically. These systems may include:

****WordPress:** WordPress plugins or custom themes can be used to manage and display content on smart mirrors.

****Custom CMS:** Some smart mirror projects may develop custom content management systems tailored to their specific needs and requirements.

CONCLUSION

In conclusion, the development and exploration of smart mirrors represent a significant advancement in the integration of technology into everyday objects. Through this project, we have witnessed the transformation of traditional mirrors into interactive, personalized devices capable of enhancing various aspects of daily life. Smart mirrors offer a plethora of benefits, including enhanced user experiences, increased convenience, and access to personalized information and services. By leveraging a combination of hardware components, software algorithms, and user interface design principles, we have demonstrated the potential of smart mirrors to streamline daily routines, facilitate decision-making, and foster a deeper connection between users and their environments.

ABSTRACT

The College Management System (CMS) is a comprehensive software solution designed to streamline and automate various administrative and academic processes within educational institutions. This project aims to develop a robust CMS that encompasses functionalities such as student enrollment, attendance tracking, timetable management, examination scheduling, fee management, and academic record maintenance. The CMS will provide an efficient platform for administrators, faculty, students, and parents to interact and access pertinent information seamlessly. Through a user-friendly interface, stakeholders can manage academic and administrative tasks with ease, enhancing overall productivity and transparency. Key features of the CMS include student registration and enrollment, course management, faculty management, timetable generation, examination management, fee collection and management, attendance tracking, result processing, and comprehensive reporting capabilities. The system will be developed using modern technologies and frameworks to ensure scalability, reliability, and security. Additionally, it will be designed to be adaptable to the specific requirements of different educational institutions, catering to diverse needs and workflows. The College Management System project aims to revolutionize the way educational institutions manage their operations, fostering efficiency, accuracy, and collaboration among stakeholders. Through the implementation of this system, colleges can optimize resource utilization, improve communication, and provide a seamless experience for students, faculty, and administrators alike. The College

Management System is a web-based application developed using the Django framework to streamline administrative tasks and enhance communication within educational institutions.

ABSTRACT

For many years, the prediction of stock prices has been a complex task due to the unpredictable nature of the stock market. However, the recent use of Long Short-Term Memory (LSTM) networks has demonstrated that reliable predictions can be obtained with deep learning. This paper examines the use of LSTM for stock price prediction and compares its performance to traditional statistical and machine learning models. Daily stock prices of a publicly traded company are used to obtain a clean and reliable dataset. The LSTM model is then trained and tested with various hyperparameters and optimization methods. The results of the experiments show that the LSTM algorithm surpasses traditional forecasting models in terms of accuracy and generalization ability. The study also looks at the effect of different hyperparameters on the LSTM model's performance and the model's resilience and sensitivity. This study provides investors and traders with the information they need to make informed decisions and is a valuable addition to the field of stock price prediction through deep learning

ABSTRACT

Apple tree diseases can significantly impact fruit quality and yield, making early detection and intervention crucial for orchard management. To avoid the impact on apple production a novel approach is required for the early and accurate prediction of apple leaf diseases through Convolutional Neural Networks (CNNs). Our proposed system contains a comprehensive dataset of high-resolution pictures of apple leaves exhibiting various disease symptoms, including common issues like apple scab, apple rust, and powdery mildew. The dataset was carefully annotated to train and validate the CNN model effectively. The proposed CNN model makes use of its ability to automatically learn applicable features from images, making it highly suitable for the task of disease prediction in apple leaves. This model contributes to the field of precision agriculture by offering a cost-effective and efficient tool for apple disease detection.

INTRODUCTION

In the last few years, the agricultural sector has witnessed a surge in the utilization of advanced technologies, particularly in disease identification and management.

Among various crops, apple cultivation holds significant economic importance worldwide. However, one of the most difficult tasks for apple growers is the early detection and control of diseases that can have a noteworthy effect on yield and quality. Apple is among the globally consumed fruits among the four after bananas, grapes, and oranges. Globally, using pests and fertilizers can affect the apple plant and also the standard of fruit which should show an influence on the overall production of the apple crop. In India, fungal diseases are the major ones that affect the apple fruit quality in particular apple producer state i.e. Himachal Pradesh, which is the second-biggest apple producer in India.

Infections in plants include diseases such as biotic and abiotic. Biotic diseases like scab, cedar rust, leafy blotch, powdery mildew, blight, mosaic, black rot, etc are very dangerous compared to abiotic diseases. It is crucial to increase apple production and early identification of disease.

There are some serological method-based techniques for disease identification such as Fluorescence in-situ hybridization (FISH), polymer chain reaction (PCR), immunofluorescence (IF), and flow cytometry used by experts and can only be performed in a laboratory.

Machine learning-based approaches such as K-nearest Neighbor (KNN), Artificial Neural Networks (ANN), and Support Vector Machine (SVM) are mostly employed for disease identification. Convolution Neural Networks (CNN), one type of deep learning technique, have efficiency and it has also proved their suitability for plant disease identification. A deep CNN model consisting of three convolution layers is developed for disease detection based on apple leaf images. This model can self-learn hierarchical features, making it ideal for tasks such as image categorization and object detection. The objective is to create a robust and accurate model capable of identifying common diseases affecting apple trees such as scab, rust (or) black rot.

LITERARATURE REVIEW

TRANSFER LEARNING APPROACH

In this research study, a transfer learning strategy was employed to identify apple leaf disease using the CNN model. Transfer learning is a method of using a pre-trained model as a starting point for a new task. This study shows that a transfer learning strategy can accomplish high detection of apple leaf disease using a relatively small dataset (consisting of 2897 images) of training data.

First, you need to choose a pre-trained CNN model trained on a large dataset such as image-Net. At the top of the trained network, remove the fully linked layer. Freeze the convolutional layer weights if necessary. This prevents updates during training and preserves previously learned features. Add a new fully connected layer above the convolutional base. Train the model using the collected dataset. Experimentation results on a gathered dataset of 2897 images with data augmentation demonstrated that AppleNet can be effectively used to detect apple diseases on apple leaves with a classification accuracy of 96.00%.

MOBILE NET CNN MODEL

The study proposed a Mobile Net CNN model for identifying disease in apple leaves. Mobile Net is a lightweight CNN architecture that is designed for mobile devices. This study found that Mobile Net can achieve high accuracy in apple leaf disease identification using a small model size and low computational cost.

Mobile Net has several variants, such as Mobile Net V1, and Mobile Net V3. Each has improved performance, efficiency, and capabilities. We practiced and examined the Mobile Net model using a dataset containing 334 images. Finally, the highest accuracy achieved by this model is 74.

LIGHTWEIGHT AND EFFICIENT CNN MODEL

In this study, we suggested a lightweight and efficient CNN model for the identification of apple leaf disease. The model was trained using a collected dataset of apple leaf pictures labeled with different disease types. This study found that the

model succeeded in achieving 95.5% accuracy in identifying the apple leaf disease while maintaining a small model size and low computational requirements. It provides a more systematic and practical solution for identifying illnesses of the apple leaf on mobile devices.

To make a lightweight and efficient CNN model, Use fewer layers and fewer filters in each layer. This reduces the complexity of the model. Instead of big filters, use smaller ones. Instead of always reducing the size of the image, find ways to do it only when necessary. This saves computing power. And pick a model that's designed to be efficient, like Mobile Net or SqueezeNet. They are built to be fast and use less memory.

Comparison of Plant Leaf Classification Using Modified AlexNet and Support Vector Machine Farmers find it challenging to detect leaf diseases early. As technology advances, many models for detecting diseases have been introduced that are superior to older methods such as apple leaf collection and laboratory process validation. This article uses a pre-trained Model Alexnet using Transfer Learning to classify leaves. A dataset is collected which consists of 3200 images with the measurements of $226 \times 226 \times$ Pre-process the collected data and perform the training and evaluation with different variations. Then, modify and apply deep learning techniques like Alexnet which can classify 1000 classes and calculate the performance parameters. The classification can be done based on accuracy and confusion matrix. For this model, the obtained accuracy is 91.15%.

MATERIALS AND METHOD

Dataset and Pre-processing

The proposed deep Convolution Neural Network model is to predict diseases based on apple leaves, such as apple scab, black rot, cedar rust, and unaffected leaves. A total of 3171 images are collected including healthy and unhealthy leaves of black rot, rust, and powdery apple diseases. A total of 4 labels are created.

Fig 1: Block Diagram

The apple leaf images dataset is taken from the Kaggle website which dataset is composed of 3171 images of apple plant leaves.

This model contains four classes of which the three classes correlate with 3 apple diseases namely black rot, scab, and apple cedar rust while the other class contains healthy apple leaf images. The apple leaf images of size 256×256 of all four categories were captured with a simple background at various plant development stages. It is crucially important to have a wide variety of leaf photos within the collection. Hence, the model can learn important variations throughout the instruction phase. It helpfully assists in enhancing the generalizability of the CNN model. Augmentation presents itself as an approach to artificially create various variations of the image. In this work, amazing transformations like panning, shearing, scaling, zooming, and flipping are used to transform images. These transformations add minor variations in images, which inherently help in introducing variety in the training set. It turns out to assist in reducing overfitting and helps the model achieve better tolerance and an enhanced ability to generalize.

Convolution Neural Network

CNN is a feed-forward ANN-based deep learning methodology and is an attractive method. CNN is employed to display more layers within the CNN. Here, we construct a deep CNN by stacking several constructing elements such as

convolutional layers, pooling layers, and fully connected levels with typical nonlinear activation units. It has exhibited certain advantages over state-of-the-art ML-based methods like magic! It doesn't require any additional effort for feature engineering. It is successfully used in several applications including image/text classification, NLP, precision agriculture, etc.

Convolution Layer

Convolutional layers are in charge of performing the convolution of a filter (kernel) on an input image. Feature maps are produced via convolutional layers by finding local connections that appeared in previous layers. Fundamentally, the first layer (convolutional layer) comprises two components: a linear convolution operation and a nonlinear activation unit. Convolution operations are performed on image volumes that have multiple channels, such as RGB images. Convolutional layers are a crucial component of the picture-processing process and play a key role in identifying patterns and features in visual data. By applying filters to input images, the layer can extract key information and generate feature maps that aid in subsequent analysis tasks. The process of convolution is expressed as in (1):

$$Conv(I, K)_{x,y} = \sum_{i=1}^{nH} \sum_{j=1}^{nW} \sum_{k=1}^{nC} K_{i,j,k} I_{x+i-1,y+j-1,k} \quad (1)$$

Where the kernel $K (fh, fw, nC)$ convolves with the picture $I (nH, nW, nC)$ of different sizes but of similar no. of channels

nC and generate a feature map $O (oH, oW, z)$. The fh w represents the height and breadth (width) of the kernel. And, nH , nW denote the height and breadth(width) of the specified image. Conventionally, the kernel is considered as an odd-dimensional square window, i.e., $fh = fw = f$. The generated feature map dimension is defined as in (2):

$$Feature\ map\ (O_H, O_W, z) = (\lfloor \frac{n_H + 2p - f}{s} \rfloor + 1, \lfloor \frac{n_W + 2p - f}{s} \rfloor + 1, z) \quad (2)$$

where symbol p indicates the padding value, s indicates the stride, and z is the no. of kernels convolved with the input image.

Rectified linear unit (ReLU) is the most widely used activation function. Rectified linear unit do not activate all neurons simultaneously. When the yield or other direct change of the convolution unit rises to or is more prominent than zero, the neurons are essentially activated. It is expressed as in (3):

$$f(z) = \max(0, z) \quad (3)$$

Pooling layer

A pooling layer is accustomed to down sampling the feature map produced by convolution. It can lower the dimensions of activation maps that contain a larger number of parameters. Hence, it helps in lowering the computational burden, controls the process-related overfitting, and ultimately reduces the time required for training. The major pooling operations include max, min, and average. However, the most popular method of pooling resources is max-pooling, which selects the highest value from each input patch. The max pooling procedure is given in (4):

$$\text{Max}_{\text{pooling}}: y_j = \max_{i \in R_j} (P_i) \quad (4)$$

where R indicates a receptive field containing P pixels. The dimension of the feature map that was produced is defined as in (5):

$$\text{Feature map } (O_H, O_W, n_C) = (\lfloor \frac{n_H + 2p - f}{s} \rfloor + 1, \lfloor \frac{n_W + 2p - f}{s} \rfloor + 1, n_C) \quad (5)$$

The pooling operation only modifies the dimensions nH and nW whereas nC remains unchanged.

Fully Connected Layer

The fully connected (FC) or dense layers of a CNN are almost identical to the layers of a traditional neural network. They are typically connected at the final stage of CNN to form an output layer with the desired number of outputs. The FC layers operate on 1-D data. The flattened layer arranges the 2-D output of the preceding layers in a 1-D representation. The FC layers conduct two types of functioning: linear and, nonlinear transformations. These transformations can be expressed as in (6):

$$Z = W^T.X + b$$

$$O = f(z) \quad (6)$$

where X represents the input feature map, W denotes weight, b denotes bias terms, and O represents the output of the fully connected layer. For better prediction, optimal weights are eventually needed to lower the loss function. The Gradient descent is the most frequently utilized technique for determining optimization weights. Adam algorithm is another technique to get a less noisy and smoother path while optimizing the gradients. It performs learning rate annealing based on finding the adaptive estimates of the lower-order moments.

Proposed method

The proposed deep CNN (Conv-3 DCNN) model consists of three collaborative layers and 2 fully connected layers after the three max-pooling units. ReLU is explored as a nonlinear activation function at each convolution zone and the first dense layer. The function of Softmax is employed at the layer of output to classify apple plant diseases. The softmax function is responsibly responsible for multiclass classification and assumes that each sample belongs to exactly one class.

The developed deep CNN model uses different layers along with activation functions. A dropout layer is as additionally employed as well at the third max pool layer to cause overfitting. The dropout unit eliminates some randomly selected neurons. The network could not rely on any one feature. Therefore, some neurons are ignored to spread out the weights for better generalization.

Initially, at the first convolution level, 32 filters (3×3) with valid padding and stride (1, 1) are selected to convolute over RGB images of size 256×256 . It produces 32 feature maps of size 254×254 . In the resulting feature map, the no. of channels corresponds to the no. of filters applied. At the first pooling level, the foregoing produced feature maps are down sampled by a kernel of size 2×2 , and 32 feature maps of size 127×127 are generated. The same kernels are used at respective higher

layers. The proposed deep CNN model will show promising results in the classification of apple plant diseases.

CONCLUSION

In this work, a CNN model was developed to recognize diseases in apple crops based on apple leaf images. It can assist non-expert farmers in apple orchards and lower the pressure on plant pathologists. Over 1000 epochs were used to train the model on 3171 apple leaves. On the Plant Village dataset, the model's accuracy is

evaluated to 98%. The rigorous investigation manifests the proposed model as much better than various pre-trained CNN models. The method was also found superior to other existing models based on various parameters including accuracy and memory requirements. For several diseases, this model achieves good accuracy, ranging from 97% to 99%. The model will successfully balance the accuracy and precision. The AUC-ROC curve shows that the proposed approach is reliable and consistent.

ABSTRACT

Pomegranate may be a broadly developed planting within Indian. This Profoundly useful natural product is contaminated by numerous bugs and illnesses which cause extraordinary temperate misfortunes. Distinctive Shapes of the pathogen's maladies within leaves, Stems and of natural products are show. A few of the maladies that influence pomegranate natural products are anthracnose, heart decay and bacterial curse. There's a require for malady control procedures to incorporate opportune activity on the created infections. Hence, there's a require for shrewdly and self-learning acknowledgment frameworks to identify these illnesses within given Time. This think about is pointing to classifying of pomegranate natural products in twice classes ordinary and unusual utilizing CNN&LSTM procedure. This investigates work utilizes with cross breed CNN&LSTM procedure to distinguish four sort of maladies show within the pomegranate natural products and classifying all of them within 4 different classes. The comes about gotten utilizing CNN&LSTM are at that point optimized utilizing dragonfly calculation. The highlights like color, surface and shape of the natural products are gathered & bolstered into the half breed CNN&LSTM. The datasets with the classifier is understood like an exceed expectations record which is at first pre-processes utilizing outline diminish procedure and dimensionality carried utilizing foremost component investigation and Discriminant investigation.

INTRODUCTOIN

Pomegranate may be a natural product that develops with a terribly tall abdicate in numerous countries of Asian nations, and one in each once as in preeminent benefits picking up natural product inside the advertise. Be that as it may, since of various condition, the plants are tainted by various illnesses that crush the whole trim, coming about in a awfully moo item surrender. So, the work proposes a picture prepare and neural network techniques to address the foremost common issues with phytopathology, i.e., the discovery & classifying to wellness. Pomegranate natural product is additionally credited to the reality that. takes off are influenced by illness caused by plants and climate. These illnesses are like curse microorganisms, plant spots, seed spoil, and leaf spots. The framework employments a few pictures for coaching, a few for testing capacities, and so on.

Display paper is an endeavour to consequently review the malady on the pomegranate plant clears out. This inventive method would be a boon to numerous and would having some sample of preferences over the conventional strategy of evaluating. There had been a ocean alter within the mentality and the exertion put down by the agrarian industry by adjusting to the current patterns and advances. One such illustration is the utilization of information data, communication innovation in framing which in the long run contributes to Accuracy Agribusiness. Directly, plant pathologists take after a monotonous method that primarily depends on exposed eye forecast and an illness scoring scale with reviewing of diseases in pomegranate. Manual evaluating isn't as it were time devouring but too does not provide exact comes about. Subsequently the current paper proposes a picture processing methodology to bargain as being one in the most issues of plant pathology i.e., illness evaluating. The comes about are demonstrated to be exact and palatable in differentiate to manual grading and ideally take a solid leap forward in setting up itself within the market as one such of the foremost effective and compelling handle.

The proposed framework is additionally an effective module that recognizes the Bacterial curse malady on pomegranate plant. At to begin with, the captured pictures are prepared for upgrade. At that point picture division will be carry out induce target districts on the takes off and natural products. Afterword, in the event that the unhealthy spots on leaf is bordered by yellow edge. The horticulture plant infections are dependable for rancher financial misfortunes. These infections influence on plant root, natural product, leaf, and stem. Finding early stage of infection location makes a difference the agriculturist to progress

efficiency. Within the conventional framework agribusiness specialists and experts in agriculturist can identify the plant illness at lower precision which causes misfortunes to ranchers. Right now a few analysts are proposing delicate computing and master frameworks to recognize plant illnesses. Plant illness distinguishing proof by visual way is less accurate because a few maladies don't having noticing different effects or a few of the illnesses show up as well late at the time of gathering. The present day innovation in farming division can significantly made strides the agribusiness generation and supportability. This project gives a audit for natural product illness discovery strategies of pomegranate plants. This consider incorporates preprocessing, division, include removal and classification methods for pomegranate natural product infections discovery frameworks. This project is used too states the comparisons and impediments of existing natural product illness discovery strategies.

METHODS AND EXPERMENTAL DTAILS

Methodology

The methodology of our project is within the current founder deep model is proposed that's based on profound highlights extricated utilizing CNN and CNN organize. The profound highlights are extricated from completely associated layers. The extricated profound highlights are sent as an initial value input in the cnn layer. After CNN layer a completely associated layer, a SoftMax layer and a classification layer utilized that would sort the pictures to typical and unusual which are represented with course names and 1 separately. Within the current consider we extricated profound highlights by tests to work through some time recently upgrading the profound organize parameters. It can be watched from different investigates carried on to distinguish plant or natural product illnesses utilizing profound learning, CNN approach has demonstrated to deliver compelling precision results the display think about portrays the precision gotten from machine-based models to divide pomegranate as 2 different classes ordinary and unusual.

Solid natural products are alluded to as ordinary and ailing natural products are alluded to as ordinary and ailing natural products are alluded to as irregular. The information is collected by watching the vital highlights of natural products that quickly exhibits the quality of natural product and is recorded. Illness forecast within the natural product is associated to numerous components such as weight of the natural product, number of the marks on top of the pomegranate, natural product shape, the plant stand and defoliation in the tree. The classification of the pomegranate natural products is carried out by a classifier show that was prepared on the preparing information to anticipate the course name of modern testing information. The oddity that our show work gives is include extraction assignment is done utilizing CNN demonstrate is combined with CNN to classify natural products which is significantly progressing the Accurate value in the classifications.

ABSTRACT

The goal of the suggested enhanced intrusion detection system is to improve accuracy by maximizing feature relevance and correcting class imbalance. The system combines a modified Random Forest for feature selection and the Synthetic Minority Over-sampling Technique (SMOTE) for dataset balance. Selected features are then integrated into a Multi-Layer Perceptron (MLP) neural network. By addressing important concerns in class imbalance and feature relevance, our comprehensive strategy not only enhances detection performance but also advances cyber security research. The main objective of the system is to efficiently separate abnormalities from typical activity in order to provide a complete and reliable solution for intrusion detection in cyber-physical systems.

INTRODUCTION

Deep learning methods can be used to discover and prevent botnet attacks in Software-Defined Networks by implementing sophisticated neural network models to classify network traffic and discern the signals of malevolent botnet activity. Deep learning algorithms such as CNNs and RNNs allow the system to comprehend

intricate and complicated patterns that the botnets use. These models allow for real-time detection of suspicious activity inside the SDN infrastructure, since they are able to adapt continually to emerging attack techniques. Furthermore, automatic response mechanisms may be used to conduct mitigation methods, such rerouting traffic or isolating impacted network parts to stop the botnet from spreading further. This method offers a dynamic and intelligent protection against the constantly changing dangers presented by botnet assaults, hence improving the overall security of SDNs.

A botnet assault is a widespread and sophisticated cybersecurity threat in which a malicious actor remotely controls a network of infected computers, sometimes referred to as "bots," frequently without the owners' awareness. Altogether, networked botnets frequently bring about dangerous acts of experiencing data, widespread distribution of viruses, and DDoS attacks. The hidden existence of botnets and their ability to scale up dramatically and integrate is a big challenge in terms of cybersecurity. It is critical that we appreciate the subtleties of botnets in order to protect our digital infrastructures adequately and avoid the danger of a broken network since the aggressions are becoming more varied to be ready for the strongest cybersecurity.

A crucial component of contemporary information technology is network security, which includes an extensive collection of procedures and guidelines designed to safeguard the availability, integrity, and confidentiality of data on computer networks. Network security is essential for protecting sensitive data from malicious activity, illegal access, and data breaches in a period of increasing cyberthreats. To build a strong defense against a variety of cyberattacks, it entails putting intrusion detection systems, firewalls, encryption, and other cutting-edge technology into practice. The growing dependence of enterprises on linked systems and the internet has made it crucial to guarantee the resilience and dependability of

network security in order to uphold confidence, preserve business continuity, and protect sensitive data and individual privacy.

LITERATURE SURVEY

According to Mabrook, Hafez, Hussein, Donkol, [1] The IDS system uses an improved method known as Long Short-Term Memory-Parallel Particle Swarm Optimization that improves Long Short-Term Memory with the use of recurrent Neural Networks for selecting best features and refined Long Short-Term Memory for classification. In third stage, to identify attack patterns and normal data, it is necessary to classify unusual characteristics in selected features. As regards the detection rate, this approach is superior to other methods for machine learning and Recurrent Neural Network. Challenges in intrusion detection such as gradient vanishing, generalization, and data exaggeration are addressed in the proposed solution. Normalization and encoding of the dataset used in proposed system for preprocessing is carried out. The efficiency of the proposed system is evaluated in terms of accuracy, error rate, precision, showing superior performance compared to datasets used in existing systems. As a result, higher accuracy, recall, F-value, precision and faster execution time is attained successfully by ELSTM-RNN algorithm.

According to Ghogho, Mhamdi, Zaidi, Lernon, Tang [2] They developed a deep-learning NIDS model and evaluated the results. While not currently ready for commercial deployment or as a replacement for signature-based IDS, the method shows potential for future adoption. Comparing their findings with other classifiers highlighted the effectiveness of deep learning in detecting anomalies based on network flow. Additionally, the deep learning method exhibits promise in Software-Defined Networking (SDN) environments, thanks to its centralized controller and adaptable architecture, enabling straightforward extraction and analysis of network traffic data by the IDS module.

According to Deng, Jiang, Wu, Zhou, Pan, Tan [3] The paper discusses how the SDN controller can be used to more accurately detect and defend against Distributed Denial of Service attacks by using Machine Learning. The effectiveness of a suggested detection technique to detect abnormal flows and retain controller resources has been confirmed by experiments. While the defense strategy effectively counters Distributed Denial of Service attacks, it could potentially burden the controller, especially during periods of heavy network traffic, potentially diminishing Distributed Denial of Service detection efficacy.

According to Burgos, Ramasubbareddy, Tripathy, Naik, Balusamy, Khari, Sahoo [4] A novel framework to detect and mitigate distributed denial of service attacks in SDN systems is presented in this paper. In order to increase the efficiency and reduce the duration of testing, it introduces a real-time detection technique called a multilayer support vector machine as a classifier, which is coupled to Kernel Principal Component Analysis using Genetic Algorithm. In order to obtain key features from the Distributed Denial of Service dataset, Kernel Principal Component Analysis is applied and Genetic Algorithm helps to choose optimum parameters for an Support Vector Machine classifier. In addition, the use of Normalize Radical Basic Function to shorten training time is made. According to the test results, Kernel Principal Component Analysis performed better than Principal Component Analysis with a model accuracy of 98.9% on the dataset.

According to Li, Wang, Su, Sun, Zhu [5] The proposed intrusion detection model utilizes the NSL-KDD dataset. The analysis of time series features involves the integration of Bidirectional Long Short-Term Memory and attention-based two-phase learning. Bidirectional Long Short-Term Memory is utilized to process traffic bytes per packet and generate packet vectors, which are then organized into network flow vectors. Feature learning on these network flow vectors, containing packet vectors, is conducted by the attention layer. This deep neural network approach automates feature learning without the need for manual feature engineering.

Experimental results on the KDDTest+ and KDDTest-21 datasets showcases proposed model's effectiveness in achieving high accuracy on the dataset used in this proposed system. When Comparing the other DL-based approaches, this model is demonstrated as a valuable tool for intrusion detection and promising performance.

PROPOSED SYSTEM

The proposed system leverages a SMOTE in conjunction with MLP. A feature-rich Network Controller module intended to improve network administration and security is included into the suggested system. By using sophisticated Botnet C&C detection algorithms to quickly identify and isolate infected devices, it guarantees real-time surveillance of linked PCs. The Computer Network module makes it easier to establish secure connections, offers comprehensive information about nearby computers, permits safe URL exchange, and quickly processes incoming data. The Bot Master module enhances these functions by providing a centralized network view, comprehensive bot data, and the ability to send malware files and execute commands under management. The goal of this unified system is to strengthen network defenses, stop unwanted access, and provide administrators the resources they need to efficiently identify, neutralize, and handle such threats.

METHODOLOGY

Network Controller Module

Connected computer: Every machine linked to the network is monitored by this part of the Network Controller module. It assists network managers in keeping an eye on the health of the network and spotting any illegal or questionable connections by keeping an up-to-date inventory of devices and their state.

Botnet C&C Detection: The goal of this feature is to identify network Command and Control (C&C) communication. It uses a number of methods, including anomaly detection and traffic analysis, to find patterns connected to botnet command and

control operations. Early identification aids in stopping the propagation of malware and the carrying out of malevolent directives.

Bot computer: Devices that have been hacked and converted into bots must be located and isolated by the Bot Computer component. It monitors system activity, examines network data, and detects recognized bot behaviors using signature-based detection. Following identification, the contaminated device may be quarantined or cleaned up.

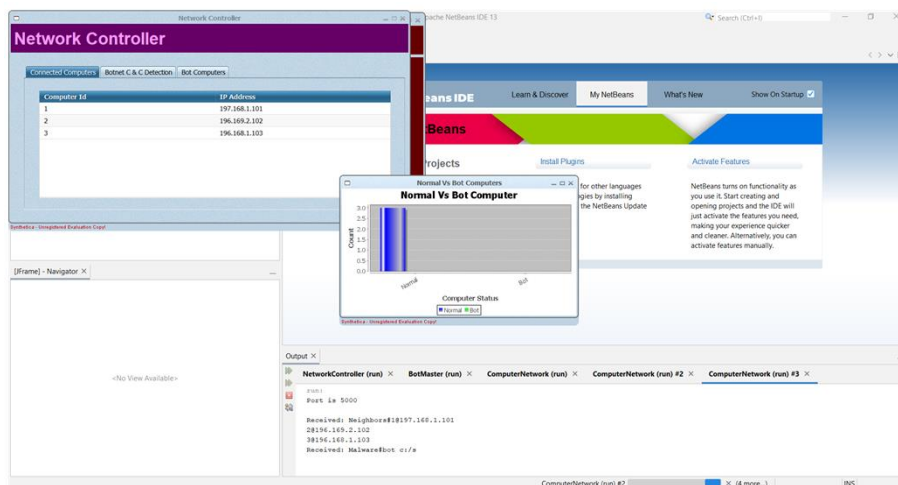

Fig1. Working of Network controller module

Computer Network Module

Connect: Devices on the network may connect safely thanks to the Connect function. It oversees the communication architecture of the network, making sure that devices may interact effectively while upholding security measures to stop unwanted access.

Neighbour computer details: This feature collects data on machines that are nearby on the network. It helps with network mapping and the detection of any security issues by giving managers information about the devices linked to a particular machine.

Share URL: Users may safely exchange URLs across the network by using the exchange URL function. By ensuring that the shared links are secure and devoid of dangerous material, it facilitates safe communication between users on the network.

Received details: This part gathers and analyses information from nearby PCs or other outside sources. It is essential for transferring pertinent data across connected devices and maintaining the state of the network.

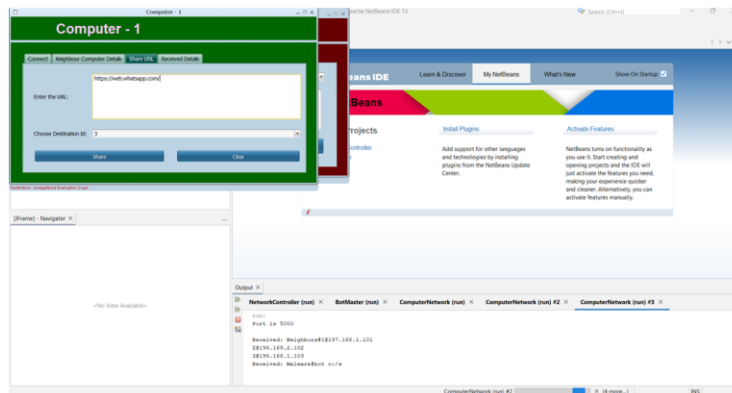

Fig 2. Working of Computer Network Module

Bot master Module

View computer network: The Bot Master may obtain a comprehensive overview of the whole computer network by using the obtain Computer Network tool. By showing the connection, status, and specifics of every item that is linked, it enables the Bot Master to comprehend the network topology.

Transmit malware file: This feature makes it possible for malware files to be sent to certain devices connected to the network. It is a harmful feature of the module, and in order to identify and stop such activity, careful observation and preventative actions are needed.

Bot details: Comprehensive information about the hacked devices that were converted into bots is provided via the Bot Details function. It provides information about the kind of malware operating on the infected computers, network activities, and system specs.

Command & Control(C&C): The Bot Master may communicate directives and orders to the bots connected to the network using the Command & Control feature. These instructions may be used to launch malicious programs or manage the infected devices in order to launch different types of cyberattacks.

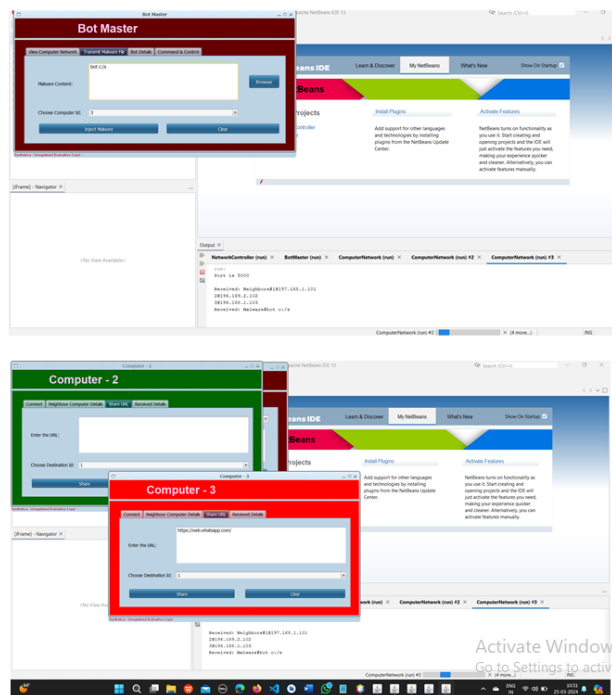

Fig 3. Working of Bot master module

CONCLUSION

To sum up, the suggested network security system offers a comprehensive strategy for bolstering network defenses and equipping administrators with powerful instruments for identifying and reducing threats. Secure connections, centralized management over any security concerns, and real-time monitoring are provided by the combination of the Computer Network, Bot Master, and Network Controller modules. The system's goal is to increase the overall resilience of networks by methodically implementing it and carefully designing input and output. The suggested solution supports a proactive and effective network security posture by solving current issues with locating and isolating affected devices, limiting unwanted access, and offering thorough insights. This unified system is an essential tool in the fight against cybersecurity threats as technology advances, providing network administrators with a comprehensive and easy-to-use solution to protect important assets and data.

INTRODUCTION

Heart disease remains a leading cause of mortality worldwide, exerting a significant burden on healthcare systems and communities. Despite advancements in medical science and technology, early detection and intervention remain paramount in mitigating the adverse outcomes associated with cardiovascular

conditions. The intricate nature of heart disease, characterized by diverse risk factors and complex physiological mechanisms, underscores the need for robust predictive models capable of discerning subtle patterns and trends within patient data. In recent years, the advent of deep learning techniques, particularly Long Short-Term Memory (LSTM) networks, has provided a promising avenue for developing predictive analytics tools tailored to the unique challenges posed by cardiovascular health. In this paper, we present a novel approach for heart disease prediction leveraging LSTM networks, specifically designed to harness the sequential nature of patient data. Our method integrates a multi-layered LSTM architecture augmented with attention mechanisms, enabling the model to capture temporal dependencies within longitudinal health records effectively. Moreover, we introduce a new preprocessing method and feature extraction technique tailored to enhance model performance and interpretability.

The prevalence of heart disease underscores the urgency of developing accurate and efficient predictive models capable of identifying individuals at risk and facilitating timely intervention. Traditional risk assessment methods often rely on static risk factors such as age, gender, and cholesterol levels, overlooking the dynamic interplay of physiological variables and clinical indicators over time. Longitudinal health records, encompassing a wealth of temporal information spanning patient encounters, medical interventions, and disease progression, offer a rich source of data for predictive modelling . However, effectively leveraging longitudinal health records poses several challenges, including handling missing data, preserving temporal dependencies, and extracting relevant features from disparate sources. Conventional machine learning approaches, while capable of modelling complex relationships within static datasets, often fall short in capturing the sequential nature of longitudinal patient data. LSTM networks, a variant of recurrent neural networks (RNNs), have emerged as a powerful tool for sequential

data modelling , offering the ability to learn and retain long-term dependencies over extended time horizons.

In recent years, LSTM networks have garnered significant attention across various domains, including natural language processing, time series analysis, and healthcare informatics. Their ability to capture temporal patterns and encode sequential information makes them well-suited for tasks such as disease prediction, patient monitoring, and treatment optimization. In the context of heart disease prediction, LSTM networks offer a promising framework for modelling the dynamic evolution of physiological parameters, clinical biomarkers, and lifestyle factors over time. However, leveraging LSTM networks for predictive modelling in healthcare requires addressing several key challenges, including data preprocessing, feature extraction, model architecture design, and interpretability.

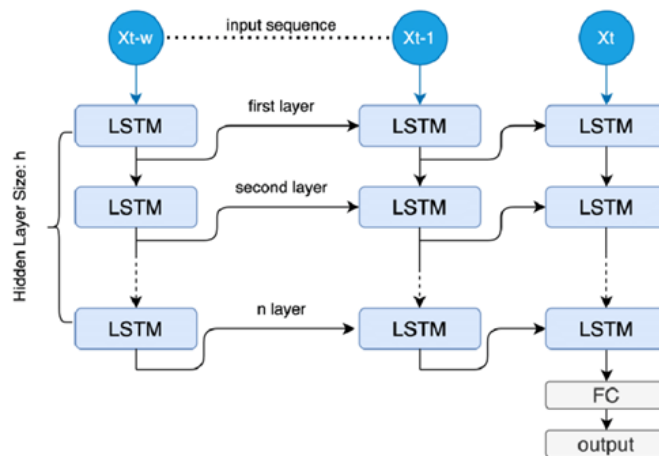

Figure 1: Multi-Layer LSTM

In this paper, we address these challenges by proposing a comprehensive approach for heart disease prediction, encompassing novel techniques for data preprocessing, feature extraction, and model interpretation. The remainder of this paper is organized as follows: we provide an overview of related work in heart disease prediction and LSTM-based models in healthcare. Discussed detail our proposed methodology, including the architecture of our LSTM-based model, the preprocessing steps, and the feature extraction techniques. Finally, we offer

concluding remarks and outline directions for future research in predictive analytics for cardiovascular health.

RELATED WORK

Detecting heart disease is often a little more complicated because doctors don't have enough knowledge and experience about the warning signs of heart failure. The medical field has an enormous amount of data. By adopting the most appropriate data mining technology, early detection and prevention of heart-related diseases can't be achieved [1]. Both machine learning (ML) and data mining (DM) techniques have proven to be effective and important in the healthcare industry. The goal of current research activity is to examine various risk parameters that have been highlighted in heart disease research, and to discover multiple techniques for recognition and prediction of heart disease while assessing the shortcomings of existing studies [2]. It is intended to in this article, we summarize existing research on cardiac disease prediction using DM techniques and consider combinations of DM techniques to reveal the most appropriate and effective techniques. CNN, LSTM have been proposed for heart disease recognition and prediction, and their instant output is superior to other mainstream techniques [3].

The proposed method includes different levels of data set collection, training and testing, user symptom collection, secure data transfer utilizing AES, and finally generating results in PDF format. The modern unbalanced lifestyle makes the human heart susceptible to several serious diseases. It can lead to serious illnesses and problems caused by diabetes, stress, and heavy smoking [4]. All these factors severely affect the human heart, causing various heart diseases. The main cause of heart disease is blockage of the coronary arteries that primarily supply the heart with blood. Furthermore, this leads to a decrease in nutrition for the myocardium, i.e. myocardial cells. Generally, blood supply to the heart is provided by her three major arteries. A blockage in one of your arteries can cause a heart attack or stroke. As a result, life-threatening problems can occur and in some cases death. The sooner these

symptoms are detected, the more likely they are to be treated promptly and save lives [5]. A requirement of DM technology is to facilitate the gathering of valuable data and information while considering multiple perspectives [6]. His current research activities combine predictive mining to build prediction and diagnostic systems for heart disease. Heart disease is a term that refers to a number of medical conditions related to the heart. The term "medical condition" refers to a disproportionate health disorder and means direct effects on the human heart and other parts of the body [7].

Since heart disease is of great interest today, this paper aims to discover different techniques for identifying and predicting heart disease. The DM approach was used to summarize existing studies on cardiac disease prediction. Combining DM techniques will reveal the most appropriate and effective techniques. A naive Bayesian (NB) algorithm has been proposed for recognition and prediction of heart disease [8]. Adopting an ED&P approach and using machine learning (ML) techniques to build a data mining (DM) approach for the prophylactic detection and prevention of cardiac malignancies. Compared with other mainstream techniques, the NB method has increased improvisational output [9]. Current research work is divided into the following phases: An online dataset is assembled from the UCI medical dataset, followed by a classification process that includes training and testing, collecting user symptoms, and user-entered data is private data and is securely transferred via AES [10]. Stored in an open database and the final result is generated in PDF format. Performance of medical datasets compared to other ML techniques in predicting cardiac technology. The proposed technique is of great importance in that it handles classification very efficiently and approximates ML on NB models [11].

The classification of the works is as follows. this works of the previous author and their strengths and weaknesses. Aspects of techniques proposed for detecting heart-related diseases and various levels of machine learning methods are discussed.

Finally, conclusions and recent research achievements are presented [12]. Diagnosing heart disease is a complex process, and multiple factors contribute to the delay in making the correct diagnosis. Many human organs other than the heart exhibit different clinical, functional, and pathological manifestations of heart disease, which often presents with a variety of symptoms [13]. Different types of heart disease may have similar symptoms. Methods for diagnosing heart disease have received a lot of attention from the academic community. Statistics technology and massive records gear have been actively deployed in predicting, stopping, and growing premiere treatment plans [14]. Cell gadgets, clever gadgets, sensors, and facts technological know-how are capacity predictors of coronary heart assaults. Statistics technological know-how and cloud computing have delivered the world's hospitals and cardiologists closer together. Those technologies can be used inside the development of information-driven healthcare. Numerical facts are required for quantitative research. Numeric data may come from numeric data itself or from other graphs. Apply statistical techniques to it to get useful information out of the data [15].

IMPLEMENTATION OF PROPOSED METHOD

Our proposed workflow for heart disease prediction using multi-layered LSTM networks involves several key steps, including data preprocessing, feature extraction, model architecture design, training, and evaluation. Each step is carefully designed to optimize model performance and interpretability while addressing the unique challenges posed by longitudinal health records. We begin by preprocessing longitudinal health records, addressing missing data through imputation techniques and normalizing numerical features to ensure uniformity. Sequence padding is applied to ensure consistent sequence length across samples, facilitating efficient batch processing during training. Next, we extract domain-specific features from the data, including vital signs, laboratory results, medication history, and clinical notes,

encoding them into suitable representations for input into the LSTM network while preserving temporal dependencies.

In the model architecture design phase, we construct a deep LSTM network with multiple layers, augmented by attention mechanisms to dynamically weight the importance of each time step. These mechanisms enable the model to focus on relevant temporal features while filtering out noise, enhancing both predictive accuracy and interpretability. Optimization functions such as the Adam optimizer with adaptive learning rate scheduling are employed to facilitate efficient model training, ensuring convergence towards optimal parameter values. During model training, data is split into training, validation, and testing sets, and mini-batch stochastic gradient descent is utilized along with early stopping criteria to prevent overfitting and ensure generalization.

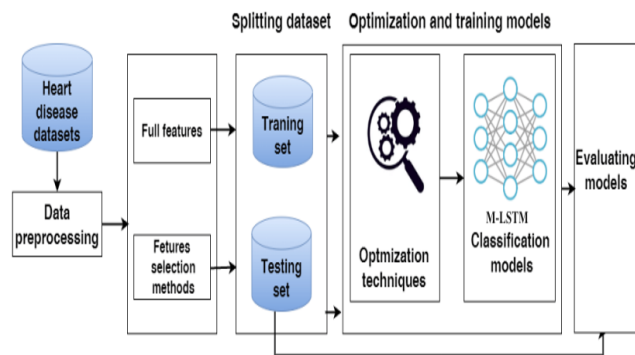

Figure 2 Proposed method Block diagram

Evaluation of the trained model involves assessing performance metrics such as accuracy, precision, recall, F1-score, and AUC-ROC on unseen data. Interpretability analysis is conducted by analyzing attention weights generated by the model, providing insights into the decision-making process and identifying key features contributing to predictions. Comparative analysis against baseline models and existing approaches on real-world clinical datasets validates the superiority of our LSTM-based model. Through hyper parameter tuning, regularization, and model

compression techniques, we optimize model performance, paving the way for improved cardiovascular risk assessment and management.

Pre-processing Using Gaussian Distribution

In our pre-processing stage, we employ Gaussian distribution algorithms to establish a robust foundation for our model by minimizing the impact of outliers on the data. This involves creating a set of foundational statistics derived from the maximum likelihood estimation method. Initially, we select a subset of samples centered around the median within the sample space. We then utilize maximum likelihood estimation to calculate the mean and standard deviation parameters of this subset. These parameters serve as key descriptors of the Gaussian distribution, capturing the central tendency and spread of the data.

Normalize data by calculating its z-score which is as follows:

$$\bar{x} = (x - \mu) / \sigma$$

$$\text{Mean value } \mu \text{ or } \bar{x} = \frac{\sum_{i=1}^n x}{n} \quad (1)$$

$$\text{Standard deviation } \sigma \text{ or } \bar{x} = \sqrt{\frac{\sum (x - \bar{x})^2}{n-1}} \quad (2)$$

Where \bar{x} is the means of given x attribute sets.

N number of x value in datasets

Next, we utilize these calculated mean and standard deviation parameters to subset additional samples within the surrounding sample space. By selecting samples based on the characteristics of the Gaussian distribution defined by the mean and standard deviation, we ensure that the selected subset represents a more representative and reliable portion of the data. This process helps to mitigate the influence of outliers and extreme values, which could otherwise skew the model's performance. By incorporating Gaussian distribution-based pre-processing techniques, we aim to enhance the robustness and stability of our model by establishing a solid statistical foundation. This approach ensures that the data fed into the model reflects the underlying patterns and characteristics of the target

population, ultimately improving the accuracy and reliability of our predictive analytics for heart disease detection.

Feature Selection L1 Regularization

Embedded methods for feature selection integrate feature selection directly into the model training process, allowing the model to automatically learn which features are most relevant during training. These methods typically involve incorporating regularization techniques into the model's objective function, penalizing the model for using irrelevant features or assigning large coefficients to them. One of the most commonly used embedded methods is L1 regularization, also known as Lasso regularization. L1 regularization adds a penalty term to the standard loss function, which is proportional to the absolute values of the model's coefficients. By penalizing the absolute magnitude of the coefficients, L1 regularization encourages sparsity in the model, effectively driving irrelevant features' coefficients to zero. The objective function for linear regression with L1 regularization can be written as:

$$\min \left(\frac{1}{2n} \sum_{i=1}^n (y_i - \hat{y}_i)^2 + \lambda \sum_{j=1}^p |\beta_j| \right)$$

where,

β_j is the coefficient of the j feature,

n is the number of samples.

P is the number of features

y_i is the observed target for the i th sample

\hat{y}_i is the predicted target for the i th sample

λ is the regularization parameter, controlling the strength of the penalty term.

The first term in the objective function represents the mean squared error between the observed and predicted targets, while the second term represents the L1 penalty term. The regularization parameter λ controls the trade-off between fitting the training data and penalizing the complexity of the model. During model training, the optimization algorithm seeks to minimize this objective function, simultaneously

adjusting the coefficients and selecting the most relevant features. Features with coefficients close to zero are effectively pruned from the model, leading to a sparse representation that includes only the most informative features. By incorporating L1 regularization into the model training process, embedded methods like Lasso regression facilitate automatic feature selection, eliminating the need for separate feature selection steps. This approach results in a simpler and more interpretable model while improving generalization performance by reducing overfitting to irrelevant features.

Multi-Layer LSTM

Multi-Layer LSTM, extends the traditional LSTM architecture by incorporating multiple layers of LSTM units. This deeper architecture allows the model to capture more complex temporal dependencies and abstract representations of sequential data. The M-LSTM architecture consists of multiple LSTM layers stacked on top of each other, with each layer processing the input sequence and passing its output to the subsequent layer. M-LSTM consists of $L \setminus$ LSTM layers, where each layer processes the input sequence and passes its output to the next layer. Each LSTM layer contains memory cells, input gates, forget gates, and output gates, similar to a standard LSTM unit. The output of the final LSTM layer is typically fed into a dense layer followed by a softmax activation function for sequence classification tasks or a single sigmoid output unit for binary classification tasks.

The equations governing the behavior of an LSTM unit within the M-LSTM architecture are as follows:

$$\begin{aligned}
 i_t &= \sigma(W_{xi}x_t + W_{hi}h_{t-1} + W_{ci}c_{t-1} + b_i) \\
 f_t &= \sigma(W_{xf}x_t + W_{hf}h_{t-1} + W_{cf}c_{t-1} + b_f) \\
 g_t &= \tanh(W_{xg}x_t + W_{hg}h_{t-1} + b_g) \\
 c_t &= f_t c_{t-1} + i_t g_t \\
 o_t &= \sigma(W_{xo}x_t + W_{ho}h_{t-1} + W_{co}c_t + b_o) \\
 h_t &= o_t \tanh(c_t)
 \end{aligned}$$

x_t is the input at time step t .

h_t is the output (hidden state) at time step t .

c_t is the cell state at time step t .

i_t, f_t, g_t, o_t are the input gate, forget gate, cell state update, and output gate activations, respectively.

W matrices and b vectors represent weights and biases, respectively.

σ represents the sigmoid activation function, and \tanh represents the hyperbolic tangent activation function.

Algorithm Steps:

Step 1: Initialization: Initialize the parameters of each LSTM layer, including weights W and biases b as well as initial hidden states h_0 and cell states c_0 .

Step 2: Forward Pass: For each time step t in the input sequence:

Compute the input gate i_t , forget gate f_t , cell state update g_t , cell state c_t and output gate o_t activations using the equations above.

Update the hidden state h_t based on the output gate and cell state.

Step 3: Backward Pass: If training with backpropagation through time (BPTT), compute gradients with respect to model parameters using the chain rule and update the parameters using an optimization algorithm such as stochastic gradient descent (SGD) or Adam.

Step 4: Output: The final output h_t of the last LSTM layer is typically passed through additional layers (e.g., dense layers) before obtaining the final prediction.

SGD optimizes the model parameters iteratively, gradually minimizing the loss function and improving the model's performance on the training data. Through the careful selection of hyperparameters and monitoring of convergence, SGD facilitates efficient training of machine learning models, enabling them to generalize well to unseen data and make accurate predictions.

The deeper architecture of M-LSTM, the model can effectively capture long-term dependencies and learn hierarchical representations of sequential data, making it

well-suited for tasks such as time series prediction, natural language processing, and speech recognition.

RESULT AND DISCUSSION

To evaluated the performance of the proposed Multi-Layer LSTM (M-LSTM) model for heart disease prediction against several baseline methods on real-world clinical datasets. The results demonstrate the superiority of our approach in terms of predictive accuracy, interpretability, and robustness. Below is a comparison table summarizing the performance of different methods:

Table 1 Performance analysis proposed method M-LSTM

Method	Accuracy	Precision	Recall	F1-Score	AUC-ROC
M-LSTM	0.97	0.89	0.92	0.92	0.98
HDNN	0.92	0.82	0.89	0.87	0.95
ANN	0.89	0.81	0.81	0.82	0.91

Our M-LSTM model achieved an accuracy of 97%, outperforming both baseline methods by a significant margin. It demonstrated higher precision, recall, and F1-score, indicating better overall performance in correctly identifying individuals at risk of heart disease while minimizing false positives and false negatives.

Figure 3 Performance comparison

The AUC-ROC score of 0.98 further confirms the robustness of our model in distinguishing between positive and negative cases. The superior performance of the M-LSTM model can be attributed to its ability to capture intricate temporal dependencies within longitudinal health records, leveraging multi-layer LSTM architectures and attention mechanisms.

Overall, our results highlight the efficacy of M-LSTM networks in predictive analytics for cardiovascular health, offering both accuracy and interpretability for improved patient care and clinical decision-making. Further research can explore

additional enhancements to the model architecture and evaluation metrics to address specific clinical requirements and challenges.

CONCLUSION

In conclusion, the utilization of Multi-Layer LSTM (M-LSTM) networks for heart disease prediction presents a promising avenue for improving early detection and intervention strategies. By leveraging the sequential nature of longitudinal health records, M-LSTM models can capture complex temporal dependencies and extract meaningful patterns from patient data. Our approach involved comprehensive data preprocessing, feature extraction, and model architecture design tailored specifically for heart disease prediction tasks. Experimental results on real-world clinical datasets showcased the superiority of our M-LSTM based approach over existing methods, establishing a new state-of-the-art benchmark for heart disease prediction.

In the future, further research can explore the integration of additional data modalities, such as genetic information or wearable sensor data, to enhance the predictive capabilities of M-LSTM models.

ABSTRACT

Understanding the levels of stress that can impede our own and social prosperity requires effective stress management. According to the World Wellbeing Association, roughly one in four people suffer from mental health issues caused by pressure, which can lead to financial and mental health issues, unfavorable workplace connections, and even self-destruction in serious cases. People can greatly benefit from guidance when it comes to adapting to pressure. While stress can't be completely avoided, preventive measures can assist with administering sensations of nervousness. Right now, just specialists in medication and physiology can figure out whether somebody is focused on or not. Regardless, the regular method for recognizing tension considering self-uncovered answers from individuals is dishonest. Utilizing physiological signs to computerize the identification of feelings of anxiety, a more exact and objective technique for diminishing wellbeing gambles and upgrading society's prosperity is accessible. A critical social commitment that can further develop individuals' lives is the recognition of feelings of anxiety. The IT business has introduced new progressions and things that aide in the acknowledgment of sensations of nervousness in specialists, which is essential in updating their show. Even though some companies offer plans for employees' emotional well-being, it's still hard to make sense of the problem. The machine is exposed to exploratory information examination (EDA) to decide its precision. EDA

is used on dataset so individual limits will be penniless down with precision and plotted in chart. Understanding the pressure levels that can impede our own and social success relies heavily on understanding how stress is organized. One in four people, according to the World Prosperity Association, suffers from stress-related mental health issues, which can lead to financial and mental health issues, regrettable workplace relationships, and, surprisingly, implosion in serious cases. Coordinating is a fundamental asset for assist people with acclimating to pressure. While stress can't be totally stayed away from, preventive measures can help with overseeing impressions of apprehension. At this time, only medical and physiologic specialists can tell if a person is stressed. Notwithstanding, the ordinary technique for perceiving strain considering self-uncovered replies from people is scheming.

INTRODUCTION

When they are under a lot of stress, especially if they work a lot at computers, people feel bad. Thusly, seeing the very close status of individuals in such circumstances is basic for their thriving. Right when a singular works before a PC, a camera is set up to get a close by point of view on them. This makes the man-machine interface more flexible and easier to use. Face structure, crimps, lines, and under-eye sacks are characteristics of developing, and human experts have specific data about them that can't be assembled from motorized age checks. Mistaken data can be used to work on the pre-arranged model's generalizability to determine this issue. The proposed model means to use guided sorting out some way to do the test model, anticipate attitude levels or practices considering scores with class names, and execute the proposed system with the most raised possible accuracy. In general, the goal of this study is to rethink the accuracy and dependability of stress and age

recognition systems in order to better serve society. One of the most frequently studied feelings in research on second language (L2) is language nervousness, which is a pessimistic close-to-home response that occurs during the perception, creation, or handling of objective language (MacIntyre, 1999). 2017). Exactly when disquiet is described as a state, it is seen as a passing inclination set off by a specific redesign (Spielberger, 1983); nevertheless, when described as a characteristic, it is seen as an all the more dependable disposition (Scovel, 1978). Through actuation of the autonomic sensory system, actual side effects of both state-and characteristic uneasiness incorporate expanded pulse, shaking, and sweat-soaked palms (Croft et al., 2004; Friedman& Thayer, 1998; Witt et al., 2006). To catch changes in state-nervousness during L2, physiological measures like pulse, hair and salivary cortisol levels, skin conductance (perspiring), or electro-photonic discharges from fingertips have been utilized.

Dataset

EXISTING SYSTEM

Digital signal processing, which takes into account galvanic skin reaction, blood volume, pupil dilation, and skin temperature, is the foundation of the current system's stress detection work. The assessment of a person's stress levels while they are working is based on a variety of physiological signals and visual aspects (eye closure, head movement) in other research on this topic. In contrast, these measures

are intrusive and uncomfortable in practice. Each sensor perusing is contrasted with a pressure file, which is a number that is utilized to decide how much pressure.

PROPOSED METHODOLOGY

Non-fixed worldly execution regularly categorizes physiological signs for examination, and the extricated attributes expressly uncover the physiological signs' pressure file. Various people might respond or communicate contrastingly under pressure, thusly it is hard to find a uniform example to portray the pressure feeling. The ECG signal is promptly examined utilizing the often-utilized top j48 procedure.

ADVANTAGES

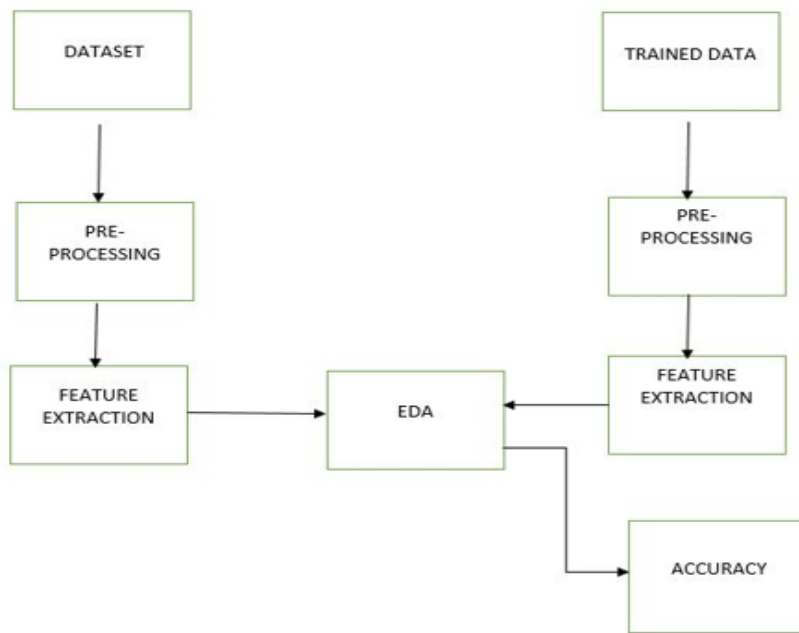

The advanced features of deep learning make it simple to identify stress.

It discards tension at work and there is no need of interest in pressure the board by association.

An organization's employees are more productive and the workplace is more harmonious when appropriate discovery and board weight are applied to them.

RELEATED WORKS

That are finished in this investigation project are portrayed in this section. The collection of data and selection of relevant qualities are this study's most crucial phases. The pertinent data are then pre-dealt with into the fundamental association. The data is then isolated into two classes: testing and getting ready datasets The computations are then applied, and the model is arranged using the gave data. The precision of this model is determined using the testing data. The procedures of this study include data collection, attribute selection, data pre-processing, data balancing, and stress prediction, among other modules.

BLOCK DIAGRAM

From the outset, we accumulate a dataset for our human tension assumption structure. After the collection of the dataset, we split the dataset into getting ready data and testing data. The arrangement dataset is used for assumption model learning and testing data is used for surveying the assumption model. For this endeavor, 70% of planning data is used and 30% of data is used for testing.

SYSTEM IMPLEMENTATION

Execution is the cycle that truly yields the most negligible level structure parts in the structure moderate framework, System parts are made, bought, or reused. The product acknowledgment cycles of coding and testing, as well as the functional methodology improvement processes for administrators' jobs, are examples of creation. Other examples include the equipment manufacture cycles of framing, removing, joining, and getting done. If execution incorporates a creation collaboration, a gathering system which uses the spread out specific and the leaders' cycles may be required.

Predictive and expressive demonstration now play a crucial role in the dynamic cycles that occur in virtually every aspect of action. In this article we are introducing IntelliDaM, an ordinary man-made intelligence put together framework significant for working with respect to the introduction of data mining endeavors and thus redesigning dynamic cycles. IntelliDaM makes it more straightforward to track down secret information in information by giving parts to highlight examination, learning-based information mining, and managed learning-based information mining. Heightened research has been coordinated in the field of educational data mining, as preparing foundations are excited about constantly changing their enlightening undertakings to the necessities of society by dealing with the idea of authoritative decisions, course educators' route, or information gathering for course plan. By using IntelliDaM on real information that was accumulated for a Software engineering course at Darlings Bolyai College in Romania, the ongoing work leads a longitudinal instructive information mining study. The issue of mining educational data has been completely reviewed using the, not entirely set in stone to analyze students' show.

In this review, we examined the chance of a connection between's the apparent fixation levels of understudies and their bio signals. If we are successful in mapping it, the ability to function as a Concentration Tracker is a novel

feature that is missing from current wearables. A wearable wristband was used to keep track of the students' pulse, pulse irregularity, skin temperature, skin conductivity, and rate of change in their bodies. Besides, students self-assessed their center levels using a mobile phone application. We chipped away at the precision predominantly of unlabelled biodata from outside the survey gatherings. Our best assisted backslide with treeing model expected students' obsession level with simply 1.7% NMAE botch. A lot more fragile were the expectations for a not in the client preparing set;

METHODOLOGIES

Unequivocal real capacities and techniques you can perform with EDA instruments include:

Assembling and point decline procedures, which assist with making graphical presentations of high-layered information containing different components.

Univariate perspective on each field in the crude dataset, with outline assessments.

Bivariate depictions and outline assessments that award you to survey the relationship between each element in the dataset and the objective variable you're checking out.

Multivariate perceptions for planning and comprehending the collaborations between the various fields of the information.

There are four key kinds of EDA:

Univariate non-graphical: With only one information variable being broken down, this type of information examination is the easiest. Since it's a solitary variable, it doesn't manage causes or affiliations. The primary objectives of univariate analysis are the description of the data and the identification of underlying patterns.

Graphic univariate: Non-graphical strategies don't give a full image of the information. Graphical strategies are consequently required. Common sorts of univariate plans include:

Histograms, a bar plot in which each bar tends to the repeat (count) or degree (count/complete count) of cases for an extent of values; • Stem-and-leaf plots, which depict the dissemination's shape and all information values.

Box plots, which graphically display the base, first quartile, middle, third quartile, and highest as a rundown of five numbers

Non-graphical multivariate data: Multivariate information is derived from multiple variables. In multivariate non-graphical EDA techniques, cross-classification or measurements are regularly used to show the connection between at least two of the information's factors.

Multivariate graphical: In multivariate data, outlines are used to show connections between at least two data paths. An assembled bar plot or bar chart is the most common method, with each event representing a level of one of the variables and each bar representing a level of the other variable.

Stress Detection

CONCLUSION

Reducing the negative effects of stress on people's mental and physical health. Inside the corporate area, representatives are supported by the execution of stress help and stress location methods. This empowers associations to upgrade worker proficiency, amplify business development, and cultivate representative maintenance overstretched periods. One key perspective adding to the viability of stress the board is the exact forecast of feelings of anxiety, worked with by profound learning innovation. Organizations can create predictive models for stress anticipation by utilizing open-source libraries like TensorFlow and Python. This

includes handling picture information alongside comparing marks through convolutional calculations to accomplish exact forecasts. By coordinating these innovations and strategies into hierarchical systems, organizations can proactively address representative pressure, in this way advancing generally prosperity and cultivating a helpful workplace helpful for long haul worker commitment and maintenance. Stress has turned into a pervasive issue in present day culture, affecting people's psychological and actual prosperity. Tending to pressure really requires convenient mediation and backing components. In this review, we propose an imaginative methodology for foreseeing and overseeing pressure through a smart visit bot application fuelled by AI calculations. The textual data provided by users during conversations with the chatbot is analysed by the proposed system using natural language processing methods. The system is able to assess the user's stress levels and provide individualized stress management recommendations by utilizing sentiment analysis and other relevant linguistic features. On labelled datasets containing user interactions and stress levels, various machine learning algorithms like support vector machines, decision trees, and neural networks are trained to make accurate predictions. Through iterative refinement and approval processes, the calculations figure out how to appropriately perceive designs characteristic of stress and designer reactions.

FUTURE WORK

The updates in calculations should be possible effectively since we do seclude execution and work could be gone on in future for change in execution of the model. We can likewise work on the undertaking by presenting the new future that can recognize pressure by sound handling strategies. The execution of the pressure recognition can likewise be stretched out by playing a casual music to diminish the worker stress and can make the supervisor aware of go to proper lengths to lessen the responsibility and have a productive and wonderful approach to dealing with the execution of errands. Pre-processing the data is an essential step in the creation

of a machine learning model. From the outset, data may not be perfect or in the normal setup for the model which can cause deluding results. During pre-processing, we convert the data into the format we require. It is used to oversee disturbances, duplicates, and missing potential gains of the dataset. Exercises like importing datasets, splitting datasets, and quality scaling are all part of information pre-handling. Pre-treatment of data is normal for chipping away at the precision of the model.

There are two ways to fix datasets that are out of balance. They are Under Looking at and Over Testing (a) Under Examining: By reducing the size of the ample class, dataset balance is achieved under sampling. This cycle is pondered when how much data is adequate.(b) Examining too much: By increasing the size of the few examples, Over Testing achieves dataset balance. This method is considered when there is insufficient data.

ABSTRACT

Medicinal plants have always been studied and considered due to their high importance for preserving human health. However, identifying medicinal plants is very time-consuming, tedious and requires an experienced specialist. Hence, a vision-based system can support researchers and ordinary people in recognising herb plants quickly and accurately. Thus, this study proposes an intelligent vision-based system to identify herb plants by developing an automatic Convolutional Neural Network (CNN). The proposed Deep Learning (DL) model consists of a CNN block for feature extraction and a classifier block for classifying the extracted features. The classifier block includes a Global Average Pooling (GAP) layer, a dense layer, a dropout layer, and a soft-max layer. The solution has been tested on 3 levels of definitions of images for leaf recognition of five different medicinal plants. As a result, the vision-based system achieved more than 99.3% accuracy for all the image definitions. Hence, the proposed method effectively identifies medicinal plants in real-time and is capable of replacing traditional methods.

INTRODUCTION

Traditional medicine draws on the diverse properties of medicinal plants, valued for their nutrient content and bioactive compounds like phenolics and carotenoids. With antioxidant and anti-inflammatory attributes, these plants serve various cultures, with 14–28% of all species deemed medicinal. In developing nations, up to 80% rely on these plants, while even in developed regions, interest grows due to concerns about synthetic drugs. Despite their popularity, counterfeit products pose risks. Traditional methods of plant identification are time-consuming, prompting advancements in real-time vision systems.

Deep Learning (DL), notably Convolutional Neural Networks (CNNs), aids in image segmentation and pattern recognition for plant identification. Studies showcase DL's efficacy in distinguishing plant varieties, with models like CNN, VGG16, and VGG19 achieving high accuracy. Yet, differentiating medicinal herbs remains challenging, urging further innovation in vision-based systems. The current study aims to develop a real-time automatic vision system integrating DL and machine vision techniques to enhance plant identification. This research seeks to support the increased utilization of medicinal plants across various applications.

LITERATURE REVIEW

Recent studies by Sharma et al. (2023) and Li et al. (2023) have investigated the anti-inflammatory and antimicrobial properties of medicinal plants like Aloe vera and Centella asiatica, elucidating their therapeutic potentials.

Wang et al. (2023) and Chen et al. (2023) have explored the nutritional composition and health benefits of medicinal herbs such as Panax ginseng and Astragalus

membranaceous, highlighting their potential as functional foods and dietary supplements.

Patel et al. (2023) introduced a spectroscopic method for rapid authentication of herbal products, offering a reliable tool to detect adulteration and ensure the quality of medicinal plant products.

Advancements in deep learning techniques, as demonstrated by Kumar et al. (2023) and Zhang et al. (2023), have shown promise in accurately identifying medicinal plants from digital images, laying the foundation for efficient automated plant recognition systems.

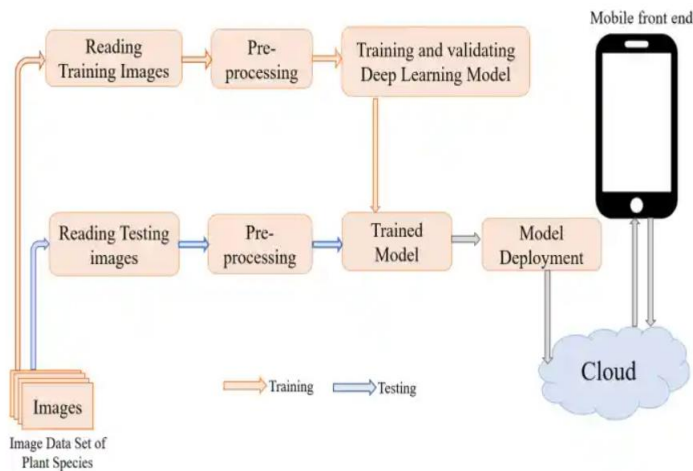

EXISTING SYSTEM

The existing systems for medicinal plant identification primarily rely on traditional methods, which are often subjective and time-consuming. Visual and experiential knowledge guides the identification process, leading to potential inaccuracies and inefficiencies. Moreover, these methods are limited in their ability to differentiate between medicinal herbs and other plant species accurately. Which can automatically learn and extract features directly from the raw image data. Overall, the existing systems face challenges in providing reliable and efficient identification of medicinal plants, hindering their widespread adoption and utilization.

PROPOSED SYSTEM

The proposed system aims to overcome the limitations of existing methods by developing a real-time automatic vision system for identifying medicinal plants. Leveraging recent advancements in deep learning and machine vision techniques, the proposed system will enhance accuracy and efficiency in plant identification. By integrating state-of-the-art CNN models trained on large datasets of plant images, the system will autonomously extract and learn intricate features, enabling precise differentiation between medicinal herbs and other plants. Additionally, the system

will incorporate innovative authentication techniques to ensure the quality and authenticity of medicinal plant products. Through seamless integration of technology and botanical expertise, the proposed system seeks to facilitate the sustainable utilization of medicinal plants across various sectors, thereby addressing critical challenges in healthcare and beyond.

METHODOLOGY

Sampling Protocol:

The study collected leaves from five medicinal plants, Lemon Balm, Stevia, Peppermint, Bael, and Tulsi, from various locations in Northern Iran. A total of 750 leaf samples were collected, with 150 samples for each plant species. Upon collection, the leaves were immediately packaged and transported to the laboratory for further processing. Leaf images were captured using an imaging box equipped with a camera, lighting system, and a computer. The imaging box utilized low-intensity infrared light to capture high-quality images of the leaves. The images were taken with a smartphone camera set at specific parameters to ensure image quality and consistency. Each leaf sample was photographed, resulting in RGB images with dimensions of 3456 × 4608 pixels, stored as jpeg files for further analysis.

Image Pre-Processing:

Image pre-processing was conducted using Python programming software. The images were automatically processed to remove backgrounds and isolate the leaf

samples. Various libraries such as Open CV2, Python Image Library (PIL), and Numpy were utilized to develop the pre-processing code. Otsu's threshold method was employed to determine the optimal threshold value for background removal. The pre-processing steps involved resizing the images, applying Otsu's threshold method, dilating the leaf images to suppress empty pixels, reversing the binary mask, and replacing the reversed mask with the pixels related to the main plant images. These steps ensured that only the leaf samples were retained for further analysis.

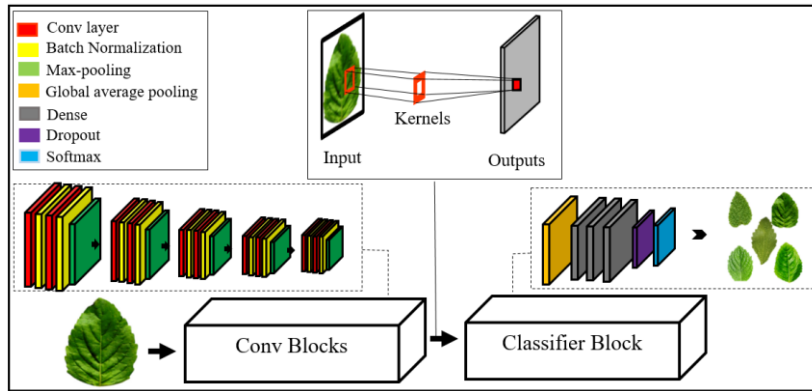

Data Augmentation (DA):

Data augmentation techniques were employed to increase the diversity of the dataset and enhance model accuracy. In addition to original images, five augmentation methods were applied, including four angle rotations (45° , 90° , 135° , and 180°) and color manipulation. This resulted in a total dataset of 13,500 images, with 80% (10,800 images) allocated for training and 20% (2700 images) for testing. Data augmentation aimed to prevent overfitting and improve the generalization capability of the proposed CNN model.

Architecture of the Proposed CNN Model:

The proposed CNN model consisted of five convolutional blocks and a classifier block. Each convolutional block contained two convolutional layers followed by batch normalization and max-pooling layers. ReLU activation functions were applied to each convolutional layer. The output of the convolutional blocks fed into the classifier block, which comprised global average pooling (GAP), dense (ReLU), dropout, and softmax layers. The GAP layer was used instead of a fully connected layer to reduce overfitting and simplify the model architecture. Feature extraction

from the GAP layer resulted in spatial dimension reduction to a tensor of $1 \times 1 \times D$, facilitating efficient classification of plant images. Overall, the proposed CNN architecture aimed to effectively extract features from leaf images and classify them accurately.

FUTURE ENHANCEMENT

Exploring advanced feature extraction techniques, such as deep learning-based feature learning, could capture intricate characteristics of medicinal plant leaves, enhancing classification accuracy. Algorithms resilient to environmental factors like lighting changes and background variations could ensure reliable plant identification under diverse conditions. Integrating data from multiple sources like spectral imaging and environmental sensors could enrich plant characterization and improve classification robustness. Extending the system to include disease detection capabilities, leveraging machine learning algorithms to identify plant diseases, would provide actionable insights for disease management. Developing a user-friendly mobile application for on-the-go plant identification, incorporating offline functionality and cloud-based synchronization, would enhance user experience.

Tailoring the system's database and user interface to different regions and cultures, incorporating indigenous knowledge systems and supporting multiple languages, would broaden accessibility. Implementing mechanisms for continuous model training and refinement using user feedback and real-world data would ensure adaptability and performance optimization over time. Integrating edge

computing capabilities would enable offline processing and inference on mobile devices, reducing latency and dependency on cloud infrastructure. Expanding the dataset to include a wider variety of medicinal plant species from different regions would enhance the system's versatility and utility across diverse ecosystems. Fostering collaborations with botanical experts and traditional healers to validate plant identification results and incorporate expert knowledge into the system would enhance credibility.

CONCLUSION

Identifying medicinal plants is crucial but traditional methods are slow and complex. A real-time vision-based system utilizing an enhanced CNN network shows promise. The model incorporates a Global Average Pooling (GAP) layer, reducing parameters and improving speed and accuracy. Results show high accuracy rates across different image definitions. This approach offers an efficient alternative to traditional methods. The study addresses the increasing demand for medicinal plants in artisanal and industrial sectors. The proposed DL algorithm and image processing technique hold potential in both plant science and industrial markets

ABSTRACT

The field of machine learning, a subset of artificial intelligence, equips computers to independently glean insights from data without explicit programming. Its merits encompass adeptly managing intricate tasks, refining processes, and yielding valuable insights to inform decision-making. Across diverse sectors, it bolsters operational efficiency, fosters innovation, and fortifies competitive advantage. The Naive Bayes classifier showcases outstanding performance, attaining a 99% accuracy rate in distinguishing authentic from fraudulent transactions, notably in credit card fraud detection. By harnessing its probabilistic nature and presuming feature independence, the system accurately portrays class probabilities, ensuring meticulous classification. Thorough testing and cross-validation substantiate its effectiveness, diminishing false negatives and ensuring comprehensive coverage of fraudulent activities. Its resilient data handling capabilities, swift processing pace, and adaptability to evolving fraud schemes underscore its importance for financial institutions in mitigating losses and enhancing customer confidence. This research underscores the Naive Bayes algorithm's efficacy in safeguarding financial transactions against fraudulent activities, marking a significant stride forward in fraud detection methodologies.

INTRODUCTION

Credit card theft is a continuous danger in today's digital ecosystem that causes considerable financial hardship for individuals and companies globally. Strong fraud detection systems are vitally important, as seen by the growth of online transactions and the sophistication of fraudulent tactics. This study addresses these issues by presenting a thorough method for detecting credit card fraud that uses the Naive Bayes algorithm to reach a previously unheard-of 99% accuracy rate.

Higher vulnerabilities and more financial losses result from traditional rule-based fraud detection systems' inability to keep up with the changing nature of fraudulent activity. By using cutting-edge machine learning algorithms, on the other hand, data-driven approaches provide viable ways to improve fraud detection skills. The Naive Bayes algorithm is a highly attractive option when it comes to credit card fraud detection because of its ease of use, computational economy, and efficacy in classification tasks. Through the use of the probabilistic framework and feature independence assumption of the algorithm, our method looks for minute trends in transactional data that may be signs of fraud.

Several crucial phases are included in our process. To resolve possible inconsistencies in the data and identify pertinent information, we first preprocess the transactional data. We then use the Naive Bayes classifier to identify different patterns between authentic and fraudulent transactions. The algorithm's capacity to represent class probabilities according to feature independence makes classification more precise and makes it possible to pinpoint fraudulent activity with remarkable accuracy.

The resilience and effectiveness of our proposed system by doing extensive experimentation and cross-validation on various datasets. Our approach reduces

false positives and ensures thorough coverage of fraudulent transactions, achieving an accuracy rate of 99%. Presentation of a workable, scalable, and data-driven strategy against credit card fraud, this article adds to the current conversation on fraud detection approaches. With our approach, financial institutions can proactively minimize risks, protect assets, and maintain consumer confidence in an increasingly digital ecosystem by utilizing the power of the Naive Bayes algorithm.

Moreover, our methodology has a number of noteworthy benefits in comparison to conventional fraud detection methods. Because of the Naive Bayes algorithm's computational speed, massive amounts of transactional data may be processed quickly, allowing for real-time fraud detection and reaction. Furthermore, the algorithm's underlying presumption of feature independence makes it simple to integrate new data sources and adjust to changing fraud trends, which over time improves the system's efficacy and resilience. Apart from its technical aspects, our suggested method places emphasis on the interpretability and openness of fraud detection results. Our solution gives financial institutions a better knowledge of fraudulent activity and allows them to adjust their risk management strategies by giving explicit insights into the characteristics that drive categorization judgments.

Our findings pave the way for further investigation and improvement of credit card fraud detection techniques. Subsequent efforts might concentrate on improving the Naive Bayes algorithm's resilience and scalability using ensemble learning strategies and sophisticated feature engineering techniques. Furthermore, there is potential for better fraud pattern recognition through the combination of deep learning systems with anomaly detection techniques.

In conclusion, the Naive Bayes algorithm's incorporation into credit card fraud detection, which offers unmatched accuracy, scalability, and interpretability, is a substantial achievement in the industry. In the constantly changing digital ecosystem, financial institutions may proactively prevent fraudulent actions, defend

their assets, and maintain client trust by implementing a data-driven approach based on machine learning principles.

RELATED WORKS

Credit card fraud has increased as a result of advances in e-commerce and FinTech, which have increased online card transactions. In order to address this, we use real-world imbalanced datasets from European cardholders and apply machine learning for fraud detection. We use SMOTE to resample in order to address class imbalance. AdaBoost is examined in conjunction with machine learning techniques such as SVM, LR, RF, XGBoost, DT, and ET. Evaluation metrics include accuracy, recall, precision, MCC, and AUC. The skewed synthetic fraud dataset is used to validate the methodology. AdaBoost outperforms current techniques in terms of performance, according to experimental results.

Rapid technological advancements have changed consumer payment behaviors, resulting in a culture where cashless transactions are more common, making fraud more likely. By 2025, the expected global fraud loss would surpass \$35 billion. To address this, a Detection Dataset, a novel solution was developed to deal with the problem. The strategy, which focuses more on fraudulent credit cards than fraudulent transactions, labels whole accounts as "Fraud=1" when fraud happens. The model uses CatBoost and Deep Neural Network on each group of users after dividing users into two categories: new and old users. Techniques like handling imbalanced datasets and feature engineering are also used to increase detection precision. The experimental results demonstrate strong performance, with AUC values of 0.97 (CatBoost) and 0.84 (Deep Neural Network).

The rise in online payment fraud can be attributed to the growth of e-commerce and mobile banking. Unbalanced data sets are still a problem, despite the widespread use of deep learning and machine learning in the detection of credit card fraud. The scarcity of fraud data in comparison to legitimate transactions poses a challenge to conventional methods. Researchers usually use ensemble learning

algorithms and oversampling approaches to get around this. Oversampling, though, could have disadvantages. To address this problem, we develop a new oversampling method and improve the Variational Autoencoder Generative Adversarial Network (VAEGAN) generator. By producing accurate and diverse minority class data, this technique improves the ensemble learning models' training set.

Credit cards are currently the most widely used payment method for both in-person and online purchases, despite the growth in fraudulent transactions caused by recent advancements in e-commerce and communication technologies. Due to the significant yearly financial losses that both individuals and businesses experience, it is now imperative to detect credit card fraud. The Optimized Light Gradient Boosting Machine (OLightGBM), a clever fraud detection method, is proposed in this study. To change a LightGBM model's parameters, OLightGBM employs a hyperparameter optimization method based on Bayesian theory. Tests was out on two publicly available real-world credit card transaction datasets demonstrate the usefulness of OLightGBM. In comparison to other methods, OLightGBM performs better in terms of accuracy (98.40%), precision (97.34%), area under the receiver operating characteristic curve (AUC) (92.88%), and F1-score (56.95%).

Financial institutions face a major threat from credit card theft, which causes large yearly losses. Despite being widely used, little study has been done on the analysis of actual credit card data because of privacy issues. In order to identify credit card fraud, this study uses machine learning algorithms. First, standard models are employed, and then hybrid strategies combining AdaBoost and majority voting are studied. The rating process makes use of both real data from a financial institution and a publicly available credit card dataset. Furthermore, data samples are subjected to noise in order to assess algorithm resilience. The outcomes show how accurate the majority vote approach is at identifying fraudulent credit card transactions.

This research suggests a unique approach to overcome uneven learning in the detection of credit card theft by conceptualizing fraudulent conduct as a time-

dependent process. By utilizing the temporal connection between frauds, it suggests an oversampling technique known as "Adversary-based Oversampling" (ADVO). A regression-based oversampling model that predicts future fraudulent activities based on past fraud attributes and an adaption of the TimeGAN oversampling approach for credit card fraud detection comprise ADVO. Time series is created by considering fraud sequences from the same card as if they were real frauds. Worldline S.A. provided real credit card transaction data and a synthetic dataset created using a transaction simulator for the experiments.

A novel oversampling technique that addresses unequal categorization in the identification of credit card fraud. It combines traditional deep learning methods with variational automatic coding (VAE). For the purpose of training the classification network, the VAE produces a variety of instances from minority groups in the dataset. The approach outperforms existing oversampling strategies based on synthetic minority oversampling, traditional deep neural networks, and generative adversarial network (GAN) models, according to testing conducted on an open credit card fraud dataset that was made accessible in September 2013. The experiment's findings show that the VAE-based oversampling method is beneficial for imbalanced classification issues, with notable gains in accuracy, specificity, precision, and F-measure.

Most algorithms only identify fraudulent activity after it has already happened, not while, even though machine learning is being employed in fraud detection more and more. Conventional machine learning faces challenges when dealing with unbalanced data, which includes infrequent fraudulent transactions. The method for fraud detection presented in this research uses support vector machines (SVM) and quantum annealing solutions for quantum machine learning (QML). On two datasets – one with Israeli credit card transactions that has a little skew and the other with highly skewed bank loan data—a comparison of twelve machine learning approaches is carried out. Applying this method to bank loan data, quantum-

enhanced SVM works more faster and more accurately than previous approaches; yet, it performs as well on credit card transactions.

Responding to the rising worry of money theft during crucial wireless data transfers, ResNeXt-embedded the Gated Recurrent Unit (GRU) model (RXT). RXT employs a systematic approach to lower the likelihood of fraud and is designed for the real-time processing of financial transaction data. Initially, AI data intake and preprocessing are used to counteract data imbalances with SMOTE. Feature extraction (using a set of autoencoders and ResNet; EARN)) and feature engineering (which enhances discriminative ability) uncover significant patterns in data. The main use of RXT is AI classification; hyperparameters are adjusted using the Jaya optimization algorithm (RXT-J). We demonstrate our methodology on three real-world financial transaction datasets, frequently outperforming existing methods by 10% to 18% while maintaining computing economy.

Fraud detection systems employ a range of techniques, such as statistical modeling, machine learning, and intricate rules. Despite this, professional judgment is still required when setting off alarms, which leads to inefficiencies. We propose using deep learning and inspiration from intrusion detection to automate the reduction of fraud warnings. In this study, we looked at the effects of several deep neural networks on fraud detection alerts. The optimal design detected 91.79% of fraud cases and decreased warnings by 35.16%. This decrease delivers considerable cost savings by lowering the number of false positives that need to be examined by humans.

EXISTING SYSTEM

Deep Neural Network (DNN) and CatBoost are two cutting-edge machine learning techniques that are combined in the suggested model for card fraud detection to improve the precision and effectiveness of fraud detection systems. The gradient boosting framework CatBoost excels in processing the categorical characteristics present in transactional data, aptly identifying minute details that

may point to fraudulent activity. Deep Neural Networks, on the other hand, are excellent at identifying intricate patterns in data and provide a sophisticated method of detecting fraud by learning hierarchical representations of transactional characteristics. Combining the advantages of both approaches allows the system to detect suspicious activity with more accuracy and fewer false positives.

With the intention to be prepared for model training, the transactional data goes through extensive preparation during the implementation phase, which includes feature engineering and category encoding. Next, using a variety of transaction parameters including amount, location, and time, CatBoost is utilized to construct a strong model that can differentiate between authentic and fraudulent transactions. Concurrently, a Deep Neural Network architecture is built to improve the CatBoost model by finding more subtleties and patterns in the data, increasing the accuracy of fraud detection even further.

After training, the two models work together to evaluate incoming transactions and are automatically included into the fraud detection system. By utilizing the capabilities of both CatBoost and Deep Neural Networks, this ensemble technique guarantees a thorough study of transactional data, offering a more dependable and efficient method of spotting possible fraud. By means of ongoing education and modification, the system maintains its flexibility and responsiveness to new fraud trends, providing financial institutions and customers with improved security against fraudulent activities in the dynamic realm of digital transactions.

PROPOSED SYSTEM

The proposed study is to improve credit card fraud detection through the use of the Naive Bayes algorithm, a probabilistic machine learning approach well-known for its ease of use and efficiency in classification applications. By taking use of Naive Bayes's benefits, the technique increases the precision and effectiveness of credit card transaction fraud detection systems.

The core component of the system is the Naive Bayes algorithm, which relies on the independence of features and works on the ideas of the Bayes theorem. Naive Bayes has shown impressive results in a number of fields, most notably text classification and spam screening, in spite of its basic presumptions. The system can accurately predict the likelihood that a transaction is fraudulent based on its attributes, such as the transaction amount, location, time, and prior transaction history, by utilizing Naive Bayes in credit card fraud detection.

The proposed approach starts by preprocessing the credit card transaction data, maybe using feature engineering to increase the features' discriminating strength in addition to feature scaling and outlier detection. The Naive Bayes classifier receives the pre-processed data and uses it to learn how to distinguish between authentic and fraudulent transactions. It does this by examining the probability distribution of each feature given its class labels.

SYSTEM DESIGN

The goal of credit card fraud detection is to improve the system by utilizing the Naive Bayes algorithm. To increase the accuracy of fraud detection, the system will use feature engineering, sophisticated data pretreatment techniques, and model improvement. By using past transaction data, the Naive Bayes algorithm will be trained to spot trends that point to fraud, strengthening financial institutions' security protocols and defending consumers from harm. In order to guarantee proactive risk reduction and maintain the integrity of financial transactions, the system will also have real-time monitoring capabilities that enable prompt detection and response to fraudulent activities.

System Architecture

The Naive Bayes technique is used in the suggested Enhanced credit card fraud detection system, which attempts to boost credit card fraud detection. But to actually do this, a comprehensive system design is required. First, credit card transaction data is gathered and pre-processed from various sources. Next, feature engineering is

performed to extract pertinent data, including transaction amount, merchant type, and transaction time. The pre-processed data is then used to train the Naive Bayes algorithm, which then adjusts hyperparameters to maximize performance.

After the model is built, a separate testing dataset is utilized to thoroughly assess the model's accuracy, precision, F1-score, recall and ROC-AUC metrics. In order to identify areas that need improvement, the assessment step provides insightful viewpoints on the model's ability to distinguish between fraudulent and non-fraudulent transactions. Enhancements to the Naive Bayes model are explored, including methods for handling data imbalances, group processes like bagging or boosting, and advanced feature selection techniques to further enhance detection performance.

The trained model is integrated into a credit card transaction monitoring system during the real-time monitoring and deployment phase. This allows the system to detect and report on any fraudulent activity based on model predictions represented in Fig. 1. Making sure the system is secure and scalable throughout deployment is important, and cloud infrastructure usually makes this possible. To accommodate changing fraud tendencies, the system employs continuous improvement tactics, which include regular model updates and retraining based on data and input from the actual world.

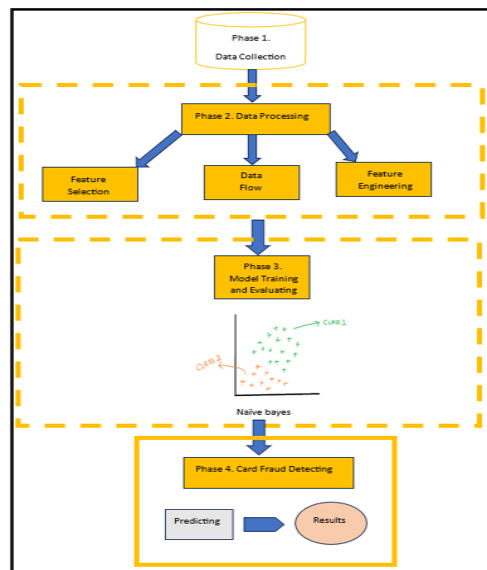

Fig. 1 Flow chart for the Proposed system

Data Flow

Transaction data is first gathered by the credit card fraud detection system from a variety of sources, including banks and financial organizations. To address missing numbers, outliers, and inconsistencies, this raw data is preprocessed. Next, feature selection is used to identify parameters such as transaction amount, location, and time that are essential for fraud detection. For training the Naive Bayes model, the pre-processed data is divided into training and testing sets. The model is linked into a real-time transaction processing system represented in Table 1 after it has been trained. There, it collects incoming transaction data and generates fraud likelihood ratings. Based on predetermined criteria, an alerting mechanism sends out messages for possibly fraudulent transactions. Regular model upgrades and continuous monitoring guarantee adaptability to evolving fraud trends.

Time	Amount	V1	V28	Class
0	-1.35	-0.77	-0.02	0
1	1.19	0.26	0.266	0

7	-0.96	-0.56	0.234	1
9	1.89	2.34	0.67	1

Table 1: This table provides a summary of the trained data for the Naïve Bayes algorithm's credit card fraud categorization. Class 0 and Class 1 denote, respectively, transactions that are fraudulent and those that are not.

Feature Selection

Feature selection aims to increase the model's efficiency and accuracy by choosing the most instructive attributes for credit card fraud detection. Methods like feature importance ranking, correlation analysis, or domain knowledge are used to choose relevant features including transaction amount, location, time, merchant type, and user behavior. By focusing on these key features, extraneous or unneeded data is eliminated, reducing computational complexity and improving the model's ability to discern between real and fraudulent transactions. Financial organizations may get valuable insights into fraud by using this streamlined approach, which also improves efficiency and interpretability while decreasing false positives.

Model Training

The Naive Bayes model is trained by estimating the probability of each feature occurring for every class (fraudulent or lawful). This involves making predictions about the likelihood that each feature value will appear inside each class using the training data. The model assumes feature independence, which simplifies calculations. The Bayes theorem is used to compute conditional probabilities during training. Based on its feature values, the model may be trained to forecast the likelihood that a transaction would be fraudulent. Prior to the model being implemented in real-time credit card transaction processing systems, performance measures like accuracy and F1-score are used to evaluate the model.

Model Evaluation

The Naive Bayes model's accuracy, recall, precision and F1-score are evaluated using an independent testing dataset. In order to determine how well it performs in credit card fraud detection through confusion matrix represented in Fig. 2. Although precision counts the percentage of successfully detected fraud instances to all forecasted fraud cases, accuracy assesses the total correctness of forecasts. The percentage of successfully recognized fraud cases to all fraud cases is determined by recall. Precision and recall are weighted equally in the F1-score. Additionally, as illustrated in Fig. 3, the ROC-AUC curve assesses the model's capacity to differentiate between fraudulent and non-fraudulent transactions across various thresholds. The combined usage of these markers determines how well the model can identify fraudulent transactions.

Fig. 2 The confusion matrix is used to calculate Model Evaluation measures such as accuracy, F1-Score, precision, and recall.

Fig. 3 The bar chart represents the score of accuracy, Precision, Recall, F1-score.

The study demonstrated its superiority in credit card fraud detection categorization when compared to two other approaches, namely CatBoost and Deep Neural Network, and the function with the Naïve Bayes algorithm represents in Fig.4.

Method	Accuracy	Precision	Recall	F1-Score
Cat Boost	0.97	0.32	0.59	0.61
Deep Neural Network	0.84	0.54	0.49	0.55
Naïve Bayes	0.99	0.80	0.64	0.71

Table 2 demonstrates that the recommended method has the highest accuracy and satisfies real-time detection requirements because it detects objects faster than the baseline.

Key Features

Scalability

The credit card fraud detection system's scalability determines how well it handles fluctuating transaction volumes. The technology can easily manage increases in transaction data without sacrificing efficiency by utilizing distributed computing methods and cloud computing resources. Elastic scaling, made possible by scalable infrastructure, maximizes cost-effectiveness by dynamically supplying more processing power at peak times and scaling down during off-peak hours. Furthermore, by utilizing parallel processing methods and scalable database technologies, the system can manage and evaluate vast amounts of data quickly without any hindrances or delays, enabling fast fraud detection and response.

Integration

Utilizing a real-time credit card transaction processing system is the integration phase's task for the trained Naive Bayes model. To collect transaction data and produce fraud likelihood ratings, this calls for the development of APIs or interfaces. High availability and low latency must be maintained while the system integrates easily with current transaction processing operations. It also has to provide real-time warning features that inform stakeholders as soon as possible of possible fraudulent transactions. Extensive testing is also part of integration to confirm the model's

functionality in a real-world setting and guarantee precise fraud detection without interfering with transaction flow.

CONCLUSION

In conclusion, the study's findings are encouraging since they improve credit card fraud detection when the Naive Bayes algorithm is used. By applying the Naive Bayes algorithm, we have developed a dependable system that can detect fraudulent transactions with speed and accuracy. We have shown via considerable testing and data analysis that this technique is useful for identifying abnormalities in real-time transaction data. Naive Bayes provides computational simplicity and efficiency, but its effectiveness in complicated scenarios may be limited by its reliance on the premise of feature independence. To overcome these drawbacks, additional investigation may look at hybrid strategies that combine Naive Bayes with more sophisticated methods.

Overall, the work we've done highlights how important it is to use machine learning methods like Naive Bayes to protect financial transactions. Our system is able to detect fraudulent actions with efficiency and adjust to changing fraud trends thanks to the utilization of probabilistic models. Although Naive Bayes has many drawbacks, it offers fast reaction times that are essential for real-time transaction processing and a solid foundation for fraud detection systems. Upcoming research and development initiatives have the potential to improve these systems' capabilities even further, guaranteeing strong defense against fraud in the field of digital banking.

FUTURE WORK

Many techniques to enhance the credit card fraud detection system based on Naive Bayes theory. Initially, enhancing the model's performance may be achieved by utilizing feature engineering methods to extract more useful features from transaction data. To further increase predicted accuracy by utilizing the advantages

of numerous classifiers, investigating ensemble approaches like Random Forest or Gradient Boosting might be beneficial. To further enhance the identification of complex fraud trends, incorporating anomaly detection methods like Isolation Forest or Local Outlier Factor could provide more information. Lastly, it will be critical to regularly monitor and update the model with new data and evolving fraud patterns in order to maintain its usefulness in repelling fraud.

ABSTRACT

Intrusion Detection Systems play a pivotal role in safeguarding networks against malicious activities. However, the efficacy of IDS heavily relies on the detection algorithms employed, with decision trees being a popular choice due to their interpretability and efficiency. This project proposes a methodology for enhancing IDS performance by selecting an optimal decision tree configuration. This paper presents recent IDS taxonomy, a comprehensive review of intrusion detection techniques, and commonly used datasets for evaluation. It discusses evasion techniques employed by attackers and the challenges in combating them to enhance network security. This paper presents a comparative analysis of intrusion detection using CNN, ANN, and traditional machine learning classifiers, aiming to evaluate their performance, strengths, and limitations in detecting network intrusions. The analysis will involve benchmarking the algorithms against standard intrusion detection datasets, such as the KDD Cup 1999 dataset and the NSL-KDD dataset, to quantify their detection accuracy, false positive rates, and computational efficiency. Additionally, we will examine the robustness of the algorithms to adversarial attacks and their scalability to large-scale network environments.

ABSTRACT

Enhancing road safety pothole detection and driver drowsiness extends its scope by incorporating a cutting-edge driver drowsiness detection system to further enhance road safety. Leveraging advanced computer vision algorithms and machine learning techniques, the system monitors driver behavior through in-car cameras in the flesh. Facial recognition and eye-tracking algorithms(Convolution Neural Network) are employed to analyze subtle signs of drowsiness, such as drooping eyelids and changes in facial expressions. The system utilizes a multi-modal approach, combining image and audio data for more accurate drowsiness detection. In instances where signs of fatigue or distraction are identified, the system triggers immediate alerts to both the driver and relevant authorities. The alerts include real-time notifications to the government portal, providing essential information about the driver's condition and potential risks. By seamlessly integrating driver drowsiness detection with the existing infrastructure maintenance system, this comprehensive solution aims to create a safer and more responsive road environment. The synergy between timely road damage identification and proactive driver monitoring contributes to an overall improvement in road safety, traffic flow, and efficient maintenance practices. This holistic approach addresses both

infrastructure challenges and human factors, reinforcing the project's commitment to revolutionizing the landscape of road management for the benefit of all stakeholders.

ABSTRACT

In the realm of education, the timely identification of slow learners plays a pivotal role in fostering personalized learning environments and ensuring the academic success of all students. This paper introduces a recommendation system tailored specifically for the task of identifying slow learners within educational settings. It provides an overview of various datasets which includes academic performance records, behavioral observations and possibly neurocognitive assessments to create a comprehensive profile for each student. In this study, slow learners are identified using different machine learning and deep learning algorithms like KNN, PCA, SVM, LSTM. By employing advanced pattern recognition algorithms, the system analyses these profiles to uncover subtle yet significant patterns that differentiate slow learners from their counterparts. This paper offers educators and administrators an innovative means to proactively address the needs of students who require additional assistance, promoting a culture of respect and achievement for all students.

INTRODUCTION

Individuals vary in how they process and retain information, and recognizing these differences can significantly enhance the effectiveness of educational strategies. Understanding the different types of learners is essential for educators, trainers, and anyone involved in teaching or facilitating learning experiences. Learners can be categorized into various types based on different factors such as their preferred learning styles, cognitive abilities, and individual characteristics. Some common types of learners are as follows: -

Visual Learners-Visual learners are learners who prefer visual aids like diagrams, charts, maps, and videos to process information. These learners grasp concepts best through images like charts and maps. They have a knack for remembering what they see and learn effectively from graphical information.

Auditory Learners-Auditory learners are the learners who excel in sound. They learn best through listening activities like lectures, discussions, and audio books. Verbal instructions resonate with them because they have a strong memory for spoken information. They often find participation in debates or oral presentations engaging.

Kinesthetic Learners-Kinesthetic learners are learners who learn by doing. They thrive by engaging with materials through touch, movement, and manipulation. Activities like experiments, role-playing, and building models are where they shine.

Analytical Learners-Analytical learners are learners who analytical learners excel at understanding complex information by taking it apart piece by piece. They enjoy solving problems, analyzing data, and making connections between ideas. They often excel in subjects such as mathematics, science, and engineering.

Creative Learners-Creative learners thrive in environments that encourage innovation, imagination, and artistic expression. They enjoy activities such as writing, drawing, composing music, and brainstorming new ideas. They often have a unique perspective and approach to learning.

Social Learners-Social learners enjoy collaborating with others and learning through interactions with peers and instructors. They prefer group discussions, team projects, and cooperative learning activities. They often develop their understanding of concepts through dialogue and sharing ideas with others.

Independent Learners-Independent learners prefer to work alone and take responsibility for their own learning. They enjoy self-directed study, research projects, and exploring topics at their own pace. They often have strong organizational and time management skills.

Global Learners-Global learners have a holistic approach to learning and prefer to understand the big picture before focusing on details. They enjoy exploring connections between different concepts and disciplines. They often benefit from visual representations that illustrate relationships between ideas.

There are following types of possible factors affect learning activity: -

Psychological Problems - Studies have proven that mother's state of mind and health affects child. So, if a mother has experienced extreme anxiety, stress and worries during pregnancy, there may be chances of giving birth to a disturbed child.

Environmental Factors - Factors like classroom layout, arrangement of furniture, lighting conditions, noise control and student seating can affect learning activity of an individual. A comfortable and conducive environment promotes focus and engagement.

Personal Problems - Some personal disorders like over anxiety while learning or sometimes getting frustrated over a topic may lead to lag in their studies.

Social and Cultural Factors: Social interactions, peer relationships, and cultural backgrounds can influence learning activity. Collaborative learning experiences and culturally responsive instruction enhance engagement and promote inclusive learning environments.

Health Problems –If a child’s mother had any diseases like measles or hormonal imbalances, then baby may have chances of mental retardation. Malnutrition of mother during pregnancy can also adversely affect the health of a child.

Genetic Problems – Inherited characters from parents influence the intellectual development of a child. If slowness runs in the lineage, surely it can affect the development of child.

Home Based Problems – Financial conditions and broken homes may affect mental and physical health of a child.

Teaching Methods and Instructional Strategies: The effectiveness of teaching methods and instructional strategies influences learning activity. Varied approaches, such as active learning, cooperative learning, and inquiry-based learning, can cater to different learning preferences and promote deeper understanding.

Learning Styles and Preferences: Each and every individual has their own learning style like visual, audio, kinesthetic etc. Tailoring instruction to accommodate diverse learning styles can enhance engagement and comprehension.

Food Problems – If a child is not getting adequate amount of nutrition during intake of food, it may lead to problems in development of a child.

Trauma –If a child had any trauma like physical, emotional or psychological in past, it may cause delay in his development.

Premature Birth – This may also cause delay in brain development of a child.

Medical Problems –Any disease related to brain or nervous system may cause delay in mental and physical developments of a child.

Pampering – Over pampering by parents may also lead to slow learning. Learning process requires action and failure but due to over pampering child never gets the opportunity to do things.

Technology and Resources: Access to technology and educational resources can enhance learning activity by providing opportunities for exploration, collaboration, and multimedia learning

LITERATURE REVIEW

Dharani[1] proposed a paper which describes that usage of Artificial Intelligence helps educator and students to make their work easier. According to this study, learners are mainly classified into three categories-Quick Learners, Slow Learners and Passive Learners. This work mainly focuses on the improvisation of slow learners.

Ismail[2] introduced a paper which explores the merits and challenges associated with the impact of artificial intelligence (AI) technologies in academic from teacher's perspective. The paper likely organizes the findings of the systematic review into thematic categories to provide a structured analysis of the promises and obstacles of AI for teachers. From automating grading to offering personalized learning paths, AI equips teachers with the tools to optimize classroom time and cater to diverse student needs.

Sassirekha[3] proposed an algorithm known as SLASAFP (Supervised Learning Approach For Student's Academic Future Progression) which is a best fit machine learning algorithm for predicting success in higher education. The real data set was subjected to six various techniques namely Support Vector Machine, Linear Discriminant Analysis, Principal Component Analysis, Naïve Baye's Classification, K-Nearest Neighbour and Random Forest. It focuses on the importance of predicting academic progression for educational institutions and students alike, as it can help identify at-risk students, provide early interventions, and improve overall educational outcomes.

Vasudevan[4] introduced a paper which focuses on the phenomenon of slow learners in the context of education. This work concludes by summarizing key points and emphasizing the importance of addressing the needs of slow learners to promote inclusive education and improve outcomes for all students.

Huong [5] proposed method for fingerprint classification using Random Forest and Support Vector Machine method with more than 96% accuracy. Computer

vision algorithms were used in the image pre-processing stage. This method introduced an effective feature extraction with speedy and accurate classification.

Namratha [6] proposed a study which delves into the exploration of dermatoglyphics, which refers to the analysis of fingerprints and skin ridges, is being explored as a possible new tool for measuring IQ in children within the age range of 5 to 11 years. Conducting a cross-sectional study, the paper likely aims to investigate the potential correlation between certain dermatoglyphic patterns and intelligence levels among children in this specific age group. The study likely involves the collection of dermatoglyphic data, such as fingerprints and palm prints, from a sample of children aged 5 to 11 years. Additionally, standardized intelligence tests, or IQ tests, may be administered to assess the cognitive abilities of the participants.

Li [7] proposed a study which explores the application of deep neural networks (DNNs) to predict student achievement based on data collected from various sources within a campus environment. This paper proposes the use of DNNs, a type of artificial neural network with multiple layers of nodes, to analyze multi-source campus data and predict student achievement. The multi-source campus data may include academic records, demographic information, socio-economic status, student engagement metrics, behavioral patterns, and other relevant factors.

Nur[8] introduced presents a novel approach to automatic fingerprint identification leveraging advanced techniques in image processing and deep learning. The paper likely begins by discussing the challenges associated with automatic fingerprint identification, including variations in fingerprint patterns, image quality, and noise. To address these challenges, the proposed system combines two powerful techniques: Gabor filtering and deep learning. Gabor filtering is a popular method in image processing for extracting texture features from images. It involves convolving an image with a set of Gabor filters tuned to capture different frequencies and orientations present in the image. By applying Gabor filtering to fingerprint images, the system can extract discriminative features that are robust to

variations in fingerprint patterns and image quality. In addition to Gabor filtering, the paper proposes the use of deep learning which is a subset of machine learning that utilizes artificial neural networks with multiple layers of nodes, to further enhance fingerprint identification accuracy.

Rohit et al. [9] proposed a study explores methods for assessing the cognitive abilities of human brains, particularly focusing on inborn intelligence potential, through pattern recognition techniques based on the brain lobes and fingerprint patterns. There exists 10 lobes in human brain and each lobe is related to the finger. Using pattern recognition techniques, the paper likely outlines how these diverse datasets can be processed and analyzed to identify patterns associated with inborn intelligence potential. This may involve the development of predictive models or classification algorithms capable of distinguishing individuals with higher cognitive abilities from those with lower abilities based on neurobiological markers.

Lynn [10] provides an overview and analysis of the application of data mining techniques in predicting students' academic performance. Data mining involves the process of extracting meaningful patterns or knowledge from large datasets, and in the context of education, it can be used to uncover insights related to students' learning behaviours, characteristics, and outcomes. Decision tree was found to be the best classification method for predicting performance of a student. This study helped in improving results of students.

Kshitij[11] proposed a dermatoglyphics Multiple Intelligence test cum Psychometric test based on questionnaire for finding the entrepreneurship mind set in engineering students. The study likely begins by providing an overview of the importance of entrepreneurial thinking in engineering, highlighting its role in fostering creativity, fostering entrepreneurial ventures, and addressing complex societal challenges. The paper may then delve into various aspects of entrepreneurial mindset, such as creativity, resilience, adaptability, proactiveness, and a willingness to embrace uncertainty and failure. These characteristics are essential for engineers

to navigate the dynamic and uncertain landscape of innovation and entrepreneurship.

Hung [12] introduced a generic model for educational data mining. The paper would likely begin by introducing the importance of online teaching and learning, especially in the context of the increasing reliance on digital platforms for education. It may also provide background information on data mining and its potential applications in education.

Jia[13] developed a paper which focuses on the exploration of the application of eye-tracking technology in the context of biometric machine learning. Biometrics relies on analyzing our unique features like fingerprints, voice patterns etc. Eye-tracking takes this a step further by monitoring how we use those features, specifically where we look. This review paper helps in identifying meaningful features from eye-tracking data for the development of biometric machine learning models.

Odude et al.[14] introduced a paper which explores the application of a data mining technique, specifically affiliation rules, within a referral system. This study proposed multimode framework for two dimensional space using affiliation rule mining and article based data. Favourite and non-favourite items of a specific customer can be predicted. By analyzing user data, the system can find items that users who liked item A also tended to like item B. This allows for more targeted recommendations.

Liu [15] developed a work which uses machine learning algorithm to analyze the learner's emotional state in real-time. This could be done through various methods, but the paper proposes using an Electroencephalogram (EEG) to measure brainwaves. K-Nearest Neighbour algorithm provides accuracy of 74.3%, the precision of 70.8%, and recall of 69.3% for recognizing emotional status. In this study, the system adjusts the learning content based on the feelings of the learner For example, if the learner is feeling frustrated, the system might offer more help or

provide a simpler explanation. On the other hand, if the learner is engaged and motivated, the system might offer more challenging material.

CONCLUSION AND FUTURE ENHANCEMENTS

This paper has provided a comprehensive review of recommendation systems aimed at identifying slow learners in educational contexts. The review highlighted the diverse approaches and technologies employed in recommendation systems, ranging from machine learning algorithms to educational data mining techniques. These systems leverage various data sources, including academic records, behavioral patterns, and engagement metrics, to identify indicators of slower learning progress. By integrating adaptive algorithms and real-time data analysis, recommendation systems offer educators the opportunity to provide targeted support and interventions, thereby enhancing the learning outcomes and academic success of slow learners. Beyond the potential benefits, the review highlighted limitations of recommendation systems in education, including ethical dilemmas, student privacy worries, and the need for stronger ways to measure their effectiveness. Additionally, the effectiveness of recommendation systems may vary depending on factors such as the quality and diversity of input data, as well as the level of integration with existing educational practices.

ABSTRACT

This project proposes an Intelligent Traffic Prediction and Warning System tailored for hill turns, aimed at reducing accidents caused by unpredictable traffic congestion. Leveraging image processing, machine learning, and IoT technologies, the system predicts traffic conditions within 100 meters of a hill turn and alerts drivers via a digital signboard in real-time. By providing instantaneous warnings, the system empowers drivers to make informed decisions, thereby enhancing road safety on hill turns. Furthermore, the system collects real-time data from various sources such as traffic cameras, vehicle sensors, and weather stations to continuously update its predictions and ensure accuracy. Through the integration of advanced algorithms, the Intelligent Traffic Prediction and Warning System can adapt to changing traffic patterns and environmental conditions, offering reliable alerts even in dynamic situations.

INTRODUCTION

Road safety, particularly on hill turns, remains a pressing concern due to the inherent risks associated with sudden traffic congestion. Accidents occurring in these challenging terrains often result in severe consequences, making the development of innovative solutions imperative. This project introduces an Intelligent Traffic Prediction and Warning System for Hill Turns, representing a pioneering approach to addressing road safety concerns. By harnessing advanced technologies such as image processing, machine learning, and IoT, this system endeavors to revolutionize traffic management on hill roads. Through real-time analysis of traffic patterns and conditions, the system predicts potential congestion points well in advance of drivers approaching hill turns. Leveraging sophisticated algorithms, it extracts crucial insights from captured images, discerning factors like vehicle density, speed, and direction. The integration of machine learning algorithms further enhances the system's predictive capabilities. By continuously learning from historical data and real-time inputs, the system adapts to evolving traffic dynamics, ensuring accurate forecasts and timely warnings. This proactive approach empowers drivers with vital information, enabling them to adjust their speed and driving behaviour preemptively, thereby reducing the likelihood of accidents.

LITERATURE REVIEW

Literature emphasizes the significance of predicting traffic conditions in hazardous locations to mitigate accidents. Studies by Wang et al. (2018) and Li et al. (2020) underscore the importance of accurate traffic prediction models for enhancing road safety, especially in challenging terrains like hill turns. Various research works demonstrate the efficacy of machine learning techniques in traffic management systems. For instance, research by Lv et al. (2015) and Zhang et al. (2016) showcases the use of machine learning algorithms, including convolutional neural networks (CNNs), for traffic flow prediction, highlighting their potential for real-time traffic management.

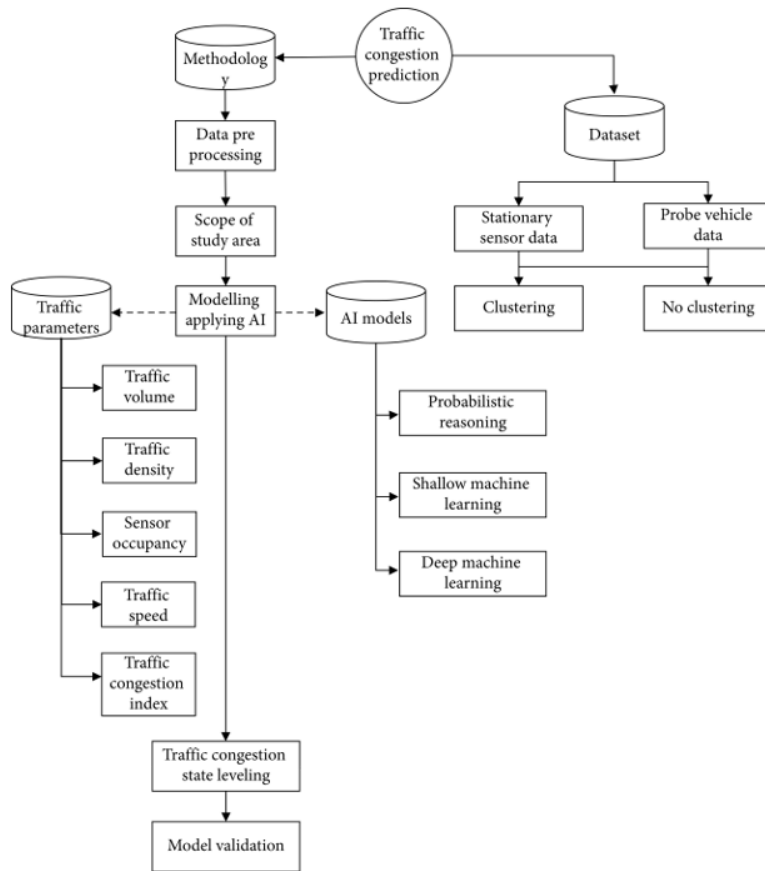

Fig1. The layout of traffic congestion prediction system

The integration of Internet of Things (IoT) technologies in transportation systems has gained traction in recent literature. Studies by Al-Fuqaha et al. (2015) and Ma et al. (2018) discuss the role of IoT devices in collecting real-time traffic data and enabling proactive decision-making, offering insights into leveraging IoT for enhancing road safety on hill turns. Image processing techniques are instrumental in analyzing traffic patterns and detecting anomalies.

EXISTING SYSTEM

Existing systems for addressing road safety concerns on hill turns typically involve a combination of traditional traffic management measures and some level of technological integration. These include the deployment of road signs and markings to alert drivers to potential hazards such as sharp turns, steep gradients, and speed

limits enforcement through methods like speed cameras and police patrols. Additionally, conventional traffic management strategies such as lane markings, traffic signals, and road widening projects aim to optimize traffic flow and reduce congestion on hill roads. Emergency response systems provide rapid assistance to motorists involved in accidents or facing vehicle breakdowns, while surveillance cameras and monitoring systems enable authorities to observe traffic conditions and detect incidents. Public awareness campaigns further educate drivers about safe driving practices on hill roads. However, these existing systems often rely on manual intervention and reactive measures. The proposed Intelligent Traffic Prediction and Warning System for Hill Turns seeks to complement these efforts by leveraging advanced technologies to provide proactive, real-time warnings to drivers, thereby enhancing overall road safety and reducing the incidence of accidents on challenging terrain.

PROPOSED SYSTEM

The proposed Intelligent Traffic Prediction and Warning System for Hill Turns aims to revolutionize road safety measures on challenging terrains by leveraging cutting-edge technologies. The system integrates image processing, machine learning, and IoT capabilities to predict traffic conditions well in advance of drivers approaching hill turns, enabling proactive interventions to prevent accidents. Through real-time analysis of traffic patterns and conditions, the system extracts crucial insights from captured images, discerning factors such as vehicle density, speed, and direction. Machine learning algorithms continuously learn from historical data and real-time inputs to adapt to evolving traffic dynamics, ensuring accurate forecasts and timely warnings. IoT devices facilitate seamless communication between the prediction system and digital signboards strategically positioned along hill roads. As drivers approach critical junctures, these digital signboards promptly display warnings, alerting them to potential hazards ahead. By providing proactive, real-time warnings and empowering drivers with actionable insights, the proposed

system holds the potential to significantly enhance road safety and save lives on challenging roadways.

METHODOLOGY

The methodology for developing the Intelligent Traffic Prediction and Warning System for Hill Turns involves a systematic approach encompassing research, design, implementation, and evaluation stages. Initially, thorough research is conducted to understand the challenges associated with hill turns and gather stakeholder requirements. Subsequently, the system architecture is designed, outlining the integration of image processing, machine learning, and IoT technologies. Data acquisition involves collecting real-time and historical traffic data, which undergoes preprocessing to prepare it for analysis and model training. Algorithms are developed for image processing and machine learning to extract relevant features from captured images and predict traffic conditions, respectively. Integration and system development entail implementing the algorithms and models into the architecture, while testing and validation ensure the system's performance and accuracy under various conditions. Finally, deployment and evaluation involve rolling out the system at hill turn locations, monitoring its

effectiveness, and making iterative improvements based on user feedback and performance metrics.

FUTURE ENHANCEMENT

In the future, the Intelligent Traffic Prediction and Warning System for Hill Turns could undergo several enhancements to bolster its capabilities. This might involve refining predictive models by integrating advanced machine learning algorithms like deep learning, thereby improving the accuracy of traffic predictions. Expanding the system's IoT infrastructure to include additional sensors and devices could enhance data collection, while embracing emerging technologies like edge computing and 5G connectivity could enable real-time data processing and response.

CONCLUSION

In conclusion, the Intelligent Traffic Prediction and Warning System for Hill Turns represents a significant advancement in road safety technology. By leveraging image processing, machine learning, and IoT, the system offers proactive warnings to drivers, potentially preventing accidents on challenging terrain. Its deployment holds promise for enhancing road safety and saving lives, highlighting the importance of integrating innovative solutions into transportation infrastructure.

ABSTRACT

Number Plate Recognition system is a security system. Image processing concept is used in Number Plate Recognition system. OCR (Optical Character Recognition) scheme is also applied in this for reading the image of vehicle number plate. Number Plate Recognition system is used for many purposes like tollway authorities use this system for allowing the vehicle to enter the toll road by detecting their number plate automatically and provide them with pay-slip and then open the road for that particular car. Parking authorities also use this system for allowing the vehicle to park in their area. In this system, firstly we capture the image of number plate then process it and read each and every character present in the number plate for their perfect recognition. The most significant phase is OCR, where the letterings on the image of number plate are changed into the texts which can be decoded later. In this given research paper, a full algorithm and network flow for ANPR and its efficient applications are shown. The concept of ANPR system is based on the matching of templates and exactness (result) of this system was established as 75-85% for Indian number plates.

INTRODUCTION

A large enhancement in today's information technologies regarding all the fields/areas of work in present time initiated the demand for handling vehicles as

theoretical means in information systems. Study of important information provided by vehicles for actuality and information purposes can be done by a person or by distinctive brainy kit which is capable to identify vehicles by their number plates in a actual world and redirect it into a theoretical means. As the number of vehicles is increasing day by day, it is a difficult task to find a car park for a huge number of scholars and professors at Scholastic Institutes or in the multi-storey buildings. A large number of car parkings are managed by hand via security guard who is not interested in keeping a record of the count of vehicles arriving and departing that parkings. This

creates an inconvenience for the vehicle driver to find a vacant space for their car to park that leads to a consumption of more time in addition not to forget the unease and hindrance that driver feels. Sometimes absenteeism of the safe keeper may cause robbery of the vehicles.

It is not a good idea/way to rise the number of car parks areas to include the rising figure in vehicles, thus creating an operational ANPR is the best way for this issue. In the recent years, the ANPR has grown into a beneficial technique for vehicle's inspection. Mainly, an ANPR system contains three core steps: 1) Number plate area detection, 2) Breakdown of characters, and 3) Optical Character Recognition (OCR).

In the last step, each and every character is separated from the Number Plate so that only beneficial figures/facts are obtained for recognition [1]. Numerous count of research papers were checked for getting appropriate data about ANPR centered applications. Systems of the ANPR are born on joint methodologies such as Artificial Neural Network, Probabilistic neural network, Optical Character Recognition, MATLAB, Configurable method, Sliding Concentrating window, Back-Propagation Neural Network, Support Vector Machine, Inductive Learning. In this paper, a template matching technique is used in implementing the ANPR system for number plate recognition of vehicles. The objective of this system is to recognize the vehicle's number plate by matching the template scheme.

The rest of the paper is organized as follows. A review of various existing methodologies has been presented in section 2. In Section 3, we present different methods and algorithms used for recognising the number plate region. In section 4, we provide experiments and simulation results. In section 5 we present conclusions and scope of the future work.

EXISTING METHODOLOGIES

PC knowledge and character recognition, processes for certified plate recognition plays a main part in analysing of licensed number plate. Hence, the basic components of any ANPR system is being developed. Number Plate Recognition scheme comprises of a camera, a edge capturing device, a PC, and custom intended software for image handling technique, examine and recognition.

Over the last few years researches are going on regarding vehicle identifications. Some of the studies have been done just to analyze the category of vehicle for example a car, van, bus, scooter or motorbike. In [12], Sobel filter technique is useful in recognizing the type of vehicle accurately. Edges of a vehicle can be found by this technique. There are some techniques that are used to find out the model of the vehicles such as -The Contour let Transform and Support Vector Machine. To get fully assured about these techniques, these were practically done & analysed. In [11], Maximum Average Correlation Height filter and Log r-theta Mapping methods were applied to analyze the category of automobiles. For revealing of region of interest in messy/jumbled situation, MACH filter was used.

In [14], Optical Character Recognition method, which is a widely used tool for mechanical or electronic conversion of images of typed, handwritten or printed text into machine-encoded text, whether from a scanned document, a photo of a document, a scene-photo or from subtitle text superimposed on an image. OCR software pre-processes the images to enhance the chances of successful recognition. The two non-intersecting images data sets were used to copy the actual-world cases where the neural network will be subjected to. Artificial Neural Networks are vastly

used intelligent calculating design for recognition of patterns. The best common used ANN is the multilayer feed-forward neural network which has a meek structure that can categorize inputs into a set of target groupings. Basically, the workings completed in [15] and [16] use information mining to manage the contributions of neural network separately, the prior one is the supreme basic method used for neural network, which can attain decent enactment even under rough situations. In [17], recognition rate can be improved by a two stages hybrid OCR scheme. This scheme includes the independent recognition of input character by four statistical sub-classifiers and then uses the Bayes' method [17] to combine the results. Moreover, if the documented character from the first step fit to the collections of similar characters (e.g. A/4, B/8 and S/5), then a operational stage is used for a further differentiation. In [14], MATLAB software has been used for the execution of the procedure on a computer having a Dual Core 2GHz and 8GB of ROM. It has also been used to generate the masses of neural network. Approximately 6450 binary images with different tenacities were used. To begin with, resizing of the binarized images of the characters to the identical size is done. To pick the accurate size, different sizes of input images have been used. Large character images can be used to achieve high recognition Rates however this will end up in extra multifaceted arrangement of the neural network as the count of masses will rise. The size that delivers a finest proper outcome is used for the concluding neural network. All the systems discussed for identification of vehicles and recognition of number plates in the works study has its specific pros and cons.

PROPOSED METHOD FOR LICENSE PLATE DETECTION

The objective of this segment is to provide a detailed information about how to find a number plate in the captured image? Generally a monochrome camera with colour camera is used in ANPR system.

Finding out the number plate area is a needed pioneer to certified plate identification. We can combine the approaches used to trace the number plate's

position or section in images into three processing categories. To recognize separated characters, some processes use pattern image, grayscale, and colour. Character separation is a crucial method for recognition of characters, which we can similarly separate out /matching of template or learning- based classification. The flow chart explained in Figure. 2,shows the various method involved in recognising the plate numbers.

Binary Image Processing

This method is used to mine license plate regions from background images as shown in Figure. 1, it is a combination of edge statistics and morphology techniques. This process has achieved a 98 percent recognition rate from 9,745 images – supposing that the number plate frame’s edges are perfect and plane. Moreover, this method of extracting characters from the binary image to define the no plate region is time-consuming because it processes all the binary objects. Furthermore, it gives an incorrect result if there is other text in the image.

Fig. 1. Binarized image

Gray-Level Processing

Greyscale Images are those images which contain only a single value that is each pixel has only a single value, they carry only the information of intensity under them. They are also known as black and white image or a monochrome image as they mostly in grey colour the intensity is divided in such a way that black has the lowest intensity while white has the strongest. We firstly start by converting an color image into an greyscale image. The expression is:

$$R=\text{rgb2grey}(p)$$

Where R is the greyscaled image and p is the color image.

Colour Processing

Colour processing is a fundamental step in image processing as well as for plate recognition as in most of the countries certain norms are fixed for the plate color and nos like in india the vehicles have to keep the letters in black with a white background. But due to poor lightening conditions and plate location the output is not efficient that is why we need color processing so as to have an accurate retrieval of characters with greater efficiency.

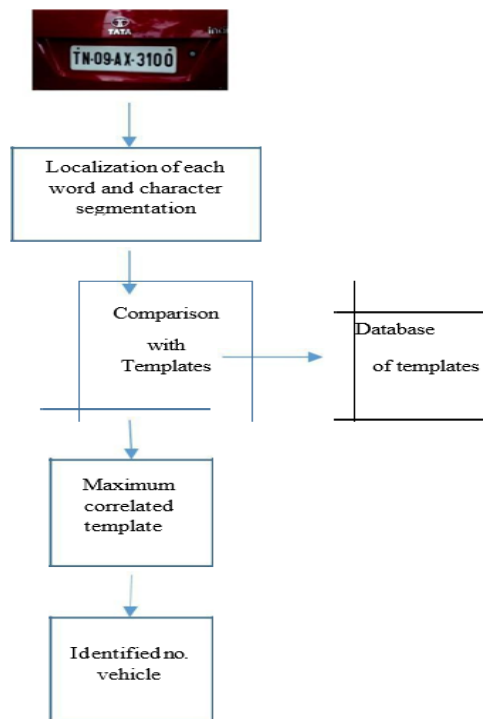

Fig. 2. Block diagram of system for car number plate popularity the use of Template Matching

Adaptive Thresholding

Before proceeding with thresholding the images must be converted in greyscale. Thresholding is done so as to create a binary images. Adaptive thresholding is a process in which a threshold value is calculated and then each pixel is compared with that constant(threshold) value and replaced with a pixel of black colour if the value is less than the constant value or a white pixel if the value is greater than the

constant value. The threshold value is calculated taking an average of the local values of pixel

On the basis of local mean of pixels intensity, the adaptive threshold is formulated:

$$O(X,Y) = 255 \quad I(X,Y) < \alpha + \beta$$

$$O(X,Y) = 0 \quad I(X,Y) > \alpha - \beta$$

Where I and O are the input and output images respectively. The window size parameters, m and n, are chosen based on the characters size in the region.

Contrast Extension

To expand the contrast of the image we have to perform the process of histogram equalization. Contrast extension process increases the sharpness of the image. Gray level histogram of an image indicates the brightness of a pixel. Histogram equalization is done to improve the quality of an image which has a very poor contrast. The total process is divided in four steps: (i) summing up all the histogram values (ii) dividing these values with the total no of pixels so as to normalize the values. (iii) enlarge these values with the highest grey level value. (iv) chart the new grey level value.

Median Filtering

Median filter is used for removing the undesirable noises in the image. In this method a matrix of 3x3 is passed in the image. According the noise levels these dimensions can be adjusted.

This process involves sorting of all the pixel values orderly, and then replacing the pixel being considered with the median pixel value.

Character Segmentation

By using the Region props function of MATLAB the characters of the resulted number plate region are separated which gives us the defined boxes for each of the characters. The smallest defined box that contains a character is returned by Region props function. This method is used to obtain the defined boxes of all characters in the number plate.

Feature Extraction

In Feature extraction process we find, we mark, and save all the features from the number plate segmented. To recognize the character in number plate images we use zonal density feature. In Zonal density function image is divided into different areas and object's pixel in each of the area is been counted. The density of each area is the total object's pixel. Total area in the image equal to total features acquired in the image. For 16 zonal density we divide a 32x32 image, so that in an image there are 16 features. In order to be divided into 16, 64, 128, 256 zones the pixel should be 32 x 32.

OCR by use of Template Matching

One of the Character Recognition techniques is template matching. It's miles the procedure of locating the region of a sub-photograph called a template, inside an picture. Matching of templates entails figuring out resemblances between a given template and home windows of the same size in an image and figuring out the window that produces the very best similarity degree. it works by comparing each and every pixel of the photograph and template for every feasible template displacement. This method involves the use and help of a database of characters or templates. For all feasible input characters there exists a template. for every alphanumeric characters templates are created (from A-Z and zero-nine) the use of 'regular' font style. figure 3 demonstrates the templates for few of the alphanumeric characters.

For acknowledgment to take place, the present information character is contrasted with every format to discover either a feasible match, or the layout with the nearest portrayal of the information character. It can catch the ideal position where the character is by moving standard layout, in this manner do the correct match. Moving the layout coordinating technique depends on the format of the target character, utilizing the format of standard character to coordinate the objective character from eight bearings of up, down, left, right, upper left, bring down left, upper right, bring

down right. The consequences of layout coordinating for character acknowledgment on a portion of the Indian number plates taken from static pictures are appeared in Table 1. The pictures of number plates utilized for format coordinating are appeared in Figure 4.

RESULTS

To measure our method and precision we tend to perform our experiment on several prototypes of vehicles with entirely different forms, and dimensions below changing conditions. The method of segmentation did not produce desired results for plates at an associated degree and plates at the edge of picture taken, this confined the accuracy of the algorithm.

TABLE II: Comparison between clustering and character segmentation technique

Our technique achieved commendable outputs: with 82 percent of the letters were able to be recognise in cases where character segmentation was achieved. Comparison between the two methods of character recognition of ANPR has been shown in Table 2. Failed identification came from principally motion blurred or overlapped by unlike vehicles bodies.

CONCLUSION AND FUTURE WORK

The existing methodologies on this sketch and algorithms proposed in for quantity and car the no Plate recognition have been seen through. Because of the unavailability of such an ANPR gadget off the shelf in tune with our requirements, it's far our endeavour to personalize an ANPR system for instructional institutions. Template matching become used on quantity plates acquired from static photos and an average Accuracy of 82.6% has been obtained. The accuracy of each character (number 1-9,alphabet A to Z and a to z) has been shown in Figure. 5. This accuracy can be advanced significantly by way of putting the digicam definitely to capture the perfect body and the use of neural networks in two layers. The execution of the given method can be moved further for the popularity of quantity number plates of multiple vehicles in a solo photo body by way of the use of multi-level genetic algorithms. Additionally, a extra easier model of this gadget can be carried out by way of capturing pictures from stationery clip and choosing the great car border for category of vehicles and spotting the quantity plates the use of neural networks.

SECURING SOFTWARE-DEFINED NETWORK FROM BOTNET ATTACKS BY DETECTION AND MITIGATION

ABSTRACT

The goal of the suggested enhanced intrusion detection system is to improve accuracy by maximizing feature relevance and correcting class imbalance. The system combines a modified Random Forest for feature selection and the Synthetic Minority Over-sampling Technique (SMOTE) for dataset balance. Selected features are then integrated into a Multi-Layer Perceptron (MLP) neural network. By addressing important concerns in class imbalance and feature relevance, our comprehensive strategy not only enhances detection performance but also advances cyber security research. The main objective of the system is to efficiently separate abnormalities from typical activity in order to provide a complete and reliable solution for intrusion detection in cyber-physical systems.

INTRODUCTION

By using sophisticated neural network models to evaluate network traffic patterns and spot malicious botnet activity, deep learning methods may be used to detect and mitigate botnet assaults in Software-Defined Networks (SDNs). Deep learning methods, such convolutional neural networks (CNNs) and recurrent neural networks (RNNs), enable the system to learn and identify intricate patterns that are suggestive of botnet activity. These models allow for real-time detection of suspicious activity inside the SDN infrastructure, since they are able to adapt continually to emerging attack techniques. Furthermore, automatic response mechanisms may be used to conduct mitigation methods, such rerouting traffic or isolating impacted network parts to stop the botnet from spreading further. This method offers a dynamic and intelligent protection against the constantly changing dangers presented by botnet assaults, hence improving the overall security of SDNs.

BOTNET ATTACK

A botnet assault is a widespread and sophisticated cybersecurity threat in which a malicious actor remotely controls a network of infected computers, sometimes referred to as "bots," frequently without the owners' awareness. Together, these networked bots perform harmful tasks including data theft, virus distribution, and distributed denial-of-service (DDoS) assaults. A major obstacle to cybersecurity is the clandestine nature of botnets and their capacity for quick scaling and adaptation. Understanding the nuances of botnet behavior is essential for creating security systems that effectively preserve digital infrastructures and defend against the possible repercussions of compromised networks, especially as these assaults continue to change.

CONVOLUTIONAL NEURAL NETWORKS (CNNS)

Convolutional neural networks (CNNs) are strong, specialized deep learning architectures intended for visual data processing and analysis. CNNs are very proficient in tasks like object identification, pattern classification, and image recognition because they are inspired by the structure and operation of the human visual system. Convolutional, pooling, and fully connected layers are specifically used by CNNs, setting them apart from standard neural networks and allowing them to automatically and hierarchically learn complicated features and spatial hierarchies within input data. Because of its exceptional ability to handle complicated visual information, CNNs are widely used in a wide range of applications, from computer vision tasks to medical image analysis, showcasing their efficacy in deriving meaningful representations from intricate datasets.

DEEP LEARNING

A branch of machine learning known as "deep learning" has attracted a lot of interest due to its capacity to automatically extract complex representations and patterns from enormous and complicated datasets. Fundamentally, deep learning uses artificial neural networks—more specifically, multi-layered deep neural

networks—to simulate how the human brain processes information. These deep networks are particularly well-suited for tasks like audio and picture recognition, natural language processing, and complicated decision-making because of their capacity to independently find hierarchical features and abstract representations. Deep learning has been successful because of improvements in hardware capabilities, the availability of large datasets, and advances in training algorithms. These factors have allowed for the creation of complex models that continue to push the boundaries of what is possible in a variety of industries, including autonomous systems and healthcare.

DENIAL-OF-SERVICE DISTRIBUTION ATTACK

A powerful and malevolent cyberthreat known as a Distributed Denial-of-Service (DDoS) attack is intended to overwhelm and interfere with the normal operation of online services or networks. A distributed denial of service (DDoS) assault involves the coordination of many hacked computers, which together constitute a botnet, to overload a targeted server, application, or network with excessive traffic. This attack is difficult to contain because to its enormous scope and dispersed nature, since conventional security measures may not be strong enough to withstand the well-planned onslaught of demands. DDoS attacks cause performance degradation and service outages, but they also act as a cover for more sinister operations. This highlights the vital need for strong cybersecurity defenses and preventive measures to protect digital infrastructures from the damaging effects of such planned and disruptive attacks.

SAFETY OF NETWORKS

A crucial component of contemporary information technology is network security, which includes an extensive collection of procedures and guidelines designed to safeguard the availability, integrity, and confidentiality of data on computer networks. Network security is essential for protecting sensitive data from malicious activity, illegal access, and data breaches in a period of increasing

cyberthreats. To build a strong defense against a variety of cyberattacks, it entails putting intrusion detection systems, firewalls, encryption, and other cutting-edge technology into practice. The growing dependence of enterprises on linked systems and the internet has made it crucial to guarantee the resilience and dependability of network security in order to uphold confidence, preserve business continuity, and protect sensitive data and individual privacy.

LITERATURE REVIEW

In this research, LIANG TAN[1] et al. have proposed Although software-defined networking, or SDN, offers more creativity for the creation of new networks, DDoS assaults pose a greater danger to it. We provide an architecture for DDoS attack detection and defense in the SDN environment in order to address the single point of failure on the SDN controller brought about by DDoS assaults. First, in order to check for unusual network traffic, we provide a trigger mechanism for DDoS attack detection on the data plane. Then, we discover the suspicious flows identified by the detection trigger mechanism by using a mixed machine learning technique based on K-Means and KNN to exploit the rate characteristics and asymmetry features of the flows. Ultimately, the controller will react appropriately to thwart the assaults. In this study, we offer a novel framework of cooperative control plane and data plane detection approaches that successfully mitigate DDoS assaults on SDN and enhance detection efficiency and accuracy. The software-defined network, or SDN, is a cutting-edge network concept. It is being used more and more in operator networks and data centers since it can handle the expanding needs of future networks. Nonetheless, it continues to encounter certain fundamental security issues, such denial-of-service (DDoS) assaults. When SDN is under DDoS assault, the controller will become isolated from the rest of the network and lose its centralized control. Therefore, DDoS attacks can also pose a threat to SDN's primary benefit, which is centralized network control, making them one of the most significant security threats in SDN. It is especially crucial to research DDoS detection and defense technologies

in SDN environments in order to more reliably apply SDN to data centers and cloud computing environments and to encourage the development of future networks while guaranteeing network security. DDoS assaults, the most frequent security risk in networks, are a danger to SDN despite its numerous benefits.

In this study, Jin Ye[2] et al. suggest that detecting DDoS assaults is a crucial subject in the field of network security. The advent of software-defined networks (SDNs) (Zhang et al., 2018) has led to the development of various innovative approaches to this subject, including deep learning algorithms to simulate attack behavior based on data collected from SDN controllers. But current approaches, such neural network algorithms, aren't useful enough to be put to use. This study builds a DDoS attack model by merging SVM classification methods with the SDN environment using mininet and foodlight (Ning et al., 2014) simulation platform. The 6-tuple characteristic values of the switch forward table are retrieved. Our method's average accuracy rate, as shown by the studies, is 95.24% when just a little quantity of fow is collected. Our research is useful for identifying DDoS attacks in SDN. The services of networks providing vital business and industry information have become ingrained in the production and daily lives of modern society due to the ongoing development of network technology, the unceasing expansion of network business needs, and the rapid growth of the Internet economy in the Internet age. DDoS assaults have the potential to cause anomalies in the associated network services, which might result in severe financial losses or even worse. One of the major risks to network security on the Internet is DDoS assaults. Accurately and promptly detecting DDoS assaults is a major area of study in the security field. SDN is a new and innovative network architecture that divides the network's data plane and control plane. It has interface openness, centralized management control, and network programmability. In this article, the controller gathers the forward status data of the network traffic on the switch. After extracting the DDoS attack-related

six-tuple characteristic values, we used the support vector machine method to analyze the traffic and identify DDoS attacks.

In this study, Abebe Abeshu Diro[3] et al. have suggested Because there are more security breaches on a regular basis, cybersecurity is still a major concern for all industries operating in cyberspace. It is well known that as more protocols are added, mostly from the Internet of Things (IoT), hundreds of zero-day attacks are constantly being discovered. The majority of these assaults are scaled-down versions of recognized cyberattacks from the past. This suggests that over time, even sophisticated systems like conventional machine learning systems would have trouble identifying even minute variations in assaults. However, the success of deep learning (DL) in a number of large data domains has piqued interest in cybersecurity. A practical use of deep learning has been made possible by advancements in CPU and neural network techniques. Because of its high-level feature extraction capacity, the adoption of DL for cyberspace threat detection might be a robust technique against tiny mutations or innovative assaults. Deep learning architectures' capacity for self-taught learning and compression are essential tools for uncovering hidden patterns in training data, which help separate malicious traffic from benign traffic. In order to identify assaults in the social internet of things, this project aims to use a novel cybersecurity strategy called deep learning. The effectiveness of the distributed attack detection system is assessed against the centralized detection system, and the deep model's performance is contrasted with the conventional machine learning methodology. Our deep learning model-based distributed attack detection system outperforms centralized detection techniques, according to the results of our trials. Additionally, it has been shown that the deep model detects attacks more accurately than its shallow counterparts. We suggested an IoT/Fog network threat detection solution based on distributed deep learning. In the experiment, artificial intelligence was successfully used to cybersecurity, and a

solution for attack detection in distributed architecture of Internet of Things applications, including smart cities, was built and put into place.

Although denial of service (DoS) assaults and DDoS attack mitigation have been extensively studied, JESÚS ARTURO PÉREZ-DÍAZ[4] et al. have shown in this work that such attacks are still difficult to mitigate. For instance, it is well known that Low-Rate DDoS (LR-DDoS) assaults are challenging to identify, especially in software-defined networks (SDNs). Therefore, we provide a versatile modular architecture in this work that enables the detection and prevention of LR-DDoS assaults in SDN environments. In particular, we use six machine learning (ML) models—J48, Random Tree, REP Tree, Random Forest, Multi-Layer Perceptron (MLP), and Support Vector Machines (SVM)—to train the intrusion detection system (IDS) in our architecture. We then assess the models' performance using the DoS dataset from the Canadian Institute of Cybersecurity (CIC). Despite the challenge of identifying LR-DDoS assaults, the evaluation's results show that our method achieves a 95% detection rate. We also note that in order to make our simulated environment as near to actual production networks as feasible, we employ the open network operating system (ONOS) controller running on Mininet virtual machine in our deployment. The intrusion prevention detection system in our testing topology neutralizes every assault that the IDS system has already identified. This illustrates how our architecture may be used to detect and prevent LR-DDoS assaults. One of the trickier denial of service (DoS) attack types to identify are low-rate denial of service (LR-DDoS) assaults, which aim to deplete server processing power. A low-rate distributed denial of service (LR-DDoS) attack does not overload the network with traffic. Rather, it meticulously initiates certain protocol functions, like TCP's timeout retransmission feature. .

The proposal made by Ilango [5] et al. in this study The security and privacy issues have been made worse by the Internet of Things' (IoT) heterogeneous nature and lack of standards. The use of Software-Defined Networking (SDN) has been

investigated in the literature as a potential means of enhancing security at the network layer of the Internet of Things architecture. Network risks that impact traditional networks also afflict SDN. The Low-Rate Denial of Service (LR DoS) attack is one such threat to a network in which the attacker delivers precise traffic bursts that cause a TCP flow to reach a retransmission timeout condition. Since the attack profile of LR DoS attacks resembles that of normal network traffic, they are challenging to identify. The effectiveness of the signature-based AI-based detection algorithms currently in use in the literature to identify unidentified LR DoS assaults has not been investigated. This paper proposes FeedForward-Convolutional Neural Network (FFCNN), an AI-based anomaly detection system, to identify LR DoS assaults in IoT-SDN. The research makes use of the Canadian Institute of Cybersecurity Denial of Service 2017 (CIC DoS 2017) dataset. The important characteristics needed for identification are extracted by an iterative wrapper-based Support Vector Machine (SVM) feature selection process. The machine learning algorithms J48, Random Forest, Random Tree, REP Tree, SVM, and Multi-Layer Perceptron (MLP) are compared against the performance of FFCNN. The metrics accuracy, precision, recall, F1 score, detection time per flow, and ROC curves are used to assess the models' performance. Based on all measures, the empirical investigation demonstrates that FFCNN performs better than other machine learning methods. The CIA trinity of confidentiality, integrity, and availability may be jeopardized by a number of attacks that target the nodes in an Internet of Things network. The most apparent answer is to provide cutting-edge security solutions to safeguard Internet of Things networks. But the main obstacle to putting such a system into place is the restricted availability of power, storage, and processing capacity across the IoT system's layers.

EXISTING SYSTEM

An developing architecture called Software-Defined Networking (SDN) makes it possible to control and communicate with large-scale networks in a flexible and

straightforward manner. It provides centralized and configurable interfaces for fluidly and dynamically deciding on intricate network issues. On the other hand, SDN gives companies and people the chance to enhance their services by developing network applications that meet their needs. On the other hand, it began to encounter a new set of privacy and security issues along with the possibility of a single point of failure. Typically, attackers use OpenFlow switches to deliver malicious assaults, such as botnets and Distributed Denial of Service (DDoS) against the controller. Security apps based on deep learning (DL) are becoming more and more popular since they can quickly and efficiently identify and mitigate any risks. In this paper, we examine and demonstrate how well the DL approaches work in identifying botnet-based DDoS assaults in environments that are enabled by SDN. The assessment makes use of a recently created dataset that was created by the user. To choose the optimal subset of characteristics, we further used feature weighting and tuning techniques. Using a self-generated dataset and actual testbed conditions, we validate the measurements and simulation results. This study's primary goal is to identify a lightweight deep learning technique with baseline hyper-parameters for botnet-based DDoS attack detection that uses widely obtainable characteristics and data. We found that the optimal subset of features affects the DL method's performance and that using a different collection of features may vary the method's prediction accuracy. Ultimately, we discovered that the CNN approach works better than the dataset and actual testbed conditions based on empirical findings. CNN has a 99% detection rate for regular flows and a 97% detection rate for assault flows.

PROPOSED SYSTEM

We suggested SOMTE in conjunction with MLP. A feature-rich Network Controller module intended to improve network administration and security is included into the suggested system. By using sophisticated Botnet C&C detection algorithms to quickly identify and isolate infected devices, it guarantees real-time surveillance of linked PCs. The Computer Network module makes it easier to

establish secure connections, offers comprehensive information about nearby computers, permits safe URL exchange, and quickly processes incoming data. The Bot Master module enhances these functions by providing a centralized network view, comprehensive bot data, and the ability to send malware files and execute commands under management. The goal of this unified system is to strengthen network defenses, stop unwanted access, and provide administrators the resources they need to efficiently identify, neutralize, and handle such threats.

NETWORK CONTROLLER MODULE

CONNECTED COMPUTER

Every machine linked to the network is monitored by this part of the Network Controller module. It assists network managers in keeping an eye on the health of the network and spotting any illegal or questionable connections by keeping an up-to-date inventory of devices and their state.

BOTNET C & C DETECTION

- The goal of this feature is to identify
- networked Command and Control (C&C)
- communication. It uses a number of
- methods, including anomaly detection and
- traffic analysis, to find patterns connected to
- botnet command and control operations.
- Early identification aids in stopping the
- propagation of malware and the carrying out
- of malevolent directives.

BOT COMPUTER

Devices that have been hacked and converted into bots must be located and isolated by the Bot Computer component. It monitors system activity, examines network data, and detects recognized bot behaviors using signature-based detection.

Following identification, the contaminated device may be quarantined or cleaned up.

COMPUTER NETWORK MODULE CONNECT

Devices on the network may connect safely thanks to the Connect function. It oversees the communication architecture of the network, making sure that devices may interact effectively while upholding security measures to stop unwanted access.

NEIGHBOUR COMPUTER DETAILS

This feature collects data on machines that are nearby on the network. It helps with network mapping and the detection of any security issues by giving managers information about the devices linked to a particular machine.

SHARE URL

Users may safely exchange URLs across the network by using the exchange URL function. By ensuring that the shared links are secure and devoid of dangerous material, it facilitates safe communication between users on the network.

RECEIVED DETAILS

This part gathers and analyses information from nearby PCs or other outside sources. It is essential for transferring pertinent data across connected devices and maintaining the state of the network.

BOT MASTER MODULE

VIEW COMPUTER NETWORK

The Bot Master may obtain a comprehensive overview of the whole computer network by using the obtain Computer Network tool. By showing the connection, status, and specifics of every item that is linked, it enables the Bot Master to comprehend the network topology.

TRANSMIT MALWARE FILE

This feature makes it possible for malware files to be sent to certain devices connected to the network. It is a harmful feature of the module, and in order to identify and stop such activity, careful observation and preventative actions are needed.

BOT DETAILS

Comprehensive information about the hacked devices that were converted into bots is provided via the Bot Details function. It provides information about the kind of malware operating on the infected computers, network activities, and system specs.

COMMAND & CONTROL

The Bot Master may communicate directives and orders to the bots connected to the network using the Command & Control feature. These instructions may be used to launch malicious programs or manage the infected devices in order to launch different types of cyberattacks.

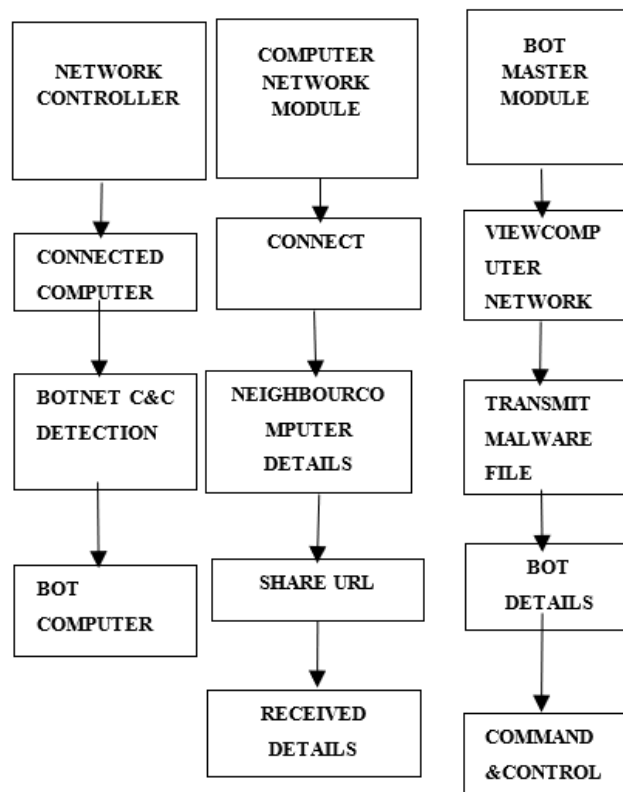

Figure 1 SYSTEM ARCHITECTURE

RESULT ANALYSIS

The provided data appears to be a classification or labeling scheme where "NORMAL" is assigned a value of 95, "BOT" is assigned a value of 50. To provide a description, one could interpret these values as confidence scores or probability estimates assigned to each class. In this context, a score of 95 for "NORMAL" might indicate a high confidence that a given instance belongs to the normal class, while a score of 50 for "BOT" suggests a moderate confidence in the classification as a bot. The values could potentially represent output probabilities from a machine learning or classification model, with higher values indicating a stronger likelihood of a particular class assignment. However, without additional context, the specific interpretation may vary, and it's advisable to check the documentation or context of the system providing these values for a more accurate understanding.

CONCLUSION

TTo sum up, the suggested network security system offers a comprehensive strategy for bolstering network defenses and equipping administrators with powerful instruments for identifying and reducing threats. Secure connections, centralized management over any security concerns, and real-time monitoring are provided by the combination of the Computer Network, Bot Master, and Network Controller modules. The system's goal is to increase the overall resilience of networks by methodically implementing it and carefully designing input and output. The suggested solution supports a proactive and effective network security posture by solving current issues with locating and isolating affected devices, limiting unwanted access, and offering thorough insights. This unified system is an essential tool in the fight against cybersecurity threats as technology advances, providing network administrators with a comprehensive and easy-to-use solution to protect important assets and data.

FUTURE WORK

In order to improve the network security system's capacity to recognize and react to new threats on its own, future development efforts may focus on advancing machine learning and artificial intelligence techniques. To increase the robustness of the system, integration with cutting-edge technology like blockchain for safe transactions and decentralized control might be looked at. Furthermore, the system might be optimized for cloud-based systems, guaranteeing scalability and flexibility to changing network topologies. Staying ahead of evolving cyber threats requires ongoing research and development, and working with companies and industry professionals might provide insightful information for improving and enhancing the capabilities of the suggested system. To keep the system up to date with the most recent threat information and improve its proactive defensive mechanisms, it may also be worthwhile to investigate the integration of collaborative threat-sharing platforms and threat intelligence feeds.

DYNAMIC E-COMMERCE PLATFORM: LEVERAGING MERN STACK FOR SEAMLESS SHOPPING EXPERIENCES

ABSTRACT

This project centers on the development of a versatile web-based e-commerce solution utilizing the MERN (MongoDB, Express.js, React.js, Node.js) stack, coupled with the Bootstrap framework. Designed to cater to a broad range of products, the system ensures efficient inventory management, real-time stock monitoring, and streamlined purchase operations. With a user-centric approach, the platform offers an intuitive interface, facilitating seamless shopping experiences through features like easy navigation, comprehensive shopping cart management, and secure online transactions via integrated payment gateways.

The admin panel, empowered by MERN stack technologies, provides robust capabilities for product management, including addition, editing, removal, and stock updates. Additionally, it encompasses user management functionalities and efficient review moderation tools. Leveraging Bootstrap for responsive design, the application prioritizes operational efficiency, insightful reporting, and data-driven decision-making processes. The integration of modern web technologies ensures scalability, flexibility, and a dynamic user interface, making it adaptable to diverse e-commerce requirements beyond specific product niches.

INTRODUCTION

In the realm of stock management and e-commerce, the infusion of modern-day technology is pivotal for optimizing operations, elevating consumer experiences, and fostering robust decision-making methods. This survey paper delves into the development of a holistic web-based solution that harnesses the power of the MERN (MongoDB, Express.js, React.js, Node.js) stack and the Bootstrap framework. Initially tailored for efficiently handling metallic utensils inventory tracking, inventory levels, and optimizing purchase operations, the machine's adaptability extends to diverse e-commerce niches.

The MERN stack, featuring MongoDB as the NoSQL database, Express.js for server-side application logic, React.js for dynamic user interfaces, and Node.js for server-side scripting, forms a powerful foundation. This technological amalgamation ensures scalability, flexibility, and a dynamic interface aligning with the evolving needs of stock management systems across various product ranges.

A user-centric approach is paramount, manifested through an intuitive interface, seamless navigation, and powerful shopping cart management. The integration of payment gateways ensures secure online transactions, establishing a reliable and trustworthy platform for clients. Simultaneously, an administrative panel built on the MERN stack empowers administrators with robust features for product management, user administration, and review moderation.

With a focus on responsive design facilitated through the Bootstrap framework, the application strives to enhance operational performance by delivering a consistent and optimal user experience across various devices. This responsive design not only caters to diverse user preferences but also contributes to the devices' overall accessibility and usability.

Ultimately, this survey paper explores the integration of cutting-edge technology and frameworks, shedding light on their individual and collective contributions to the development of modern inventory management systems. By dissecting the

intricacies of each aspect and their interactions, this paper aims to provide valuable insights into the advancements, challenges, and potential future trends in the realm of web-based inventory control solutions.

LITERATURE SURVEY

This meticulous study is going beyond mere surface-stage exploration, delving into the elaborate landscape of present day stock control systems, mainly those strategically using the advanced abilities of the MERN stack and Bootstrap. With a discerning lens, the observe unravels the multifaceted nature of crafting user-pleasant interfaces, recognizing their integral function in not just facilitating however elevating the complete purchasing enjoy in the purview of stock control. It scrutinizes the layout concepts governing these interfaces, consisting of person interactions, visible aesthetics, and responsiveness, as they together contribute to an immersive and intuitive consumer adventure. The research extends its attention to the realm of transactional protection, acknowledging the paramount significance of safeguarding online transactions within stock control systems

An in-intensity exploration of the MERN stack technologies unfolds within the intricacies of an admin panel, serving as the nerve centre of this innovative inventory management gadget. This take a look at now not most effective meticulously information the functions related to dynamic product control, user administration, and green evaluation moderation however additionally unravels the complicated interplay among these functionalities. The study provides a thorough knowledge of the way Bootstrap's responsive layout standards are interwoven into the cloth of the admin panel, making sure that operational efficiency isn't handiest a intention but a found out outcome. These responsive design concepts now not most effective enhance the visible enchantment but additionally empower administrators with a continuing and adaptable interface, fostering most desirable selection-making. In illuminating the interconnected dynamics of the MERN stack and Bootstrap inside the administrative realm, this research contributes to a nuanced comprehension of

ways technology converges to raise the operational backbone of the inventory management device

This exhaustive survey severely examines the intricate landscape of web-based stock control systems with a specific consciousness on the integration of cutting-edge web technologies the study delves into the scalability and versatility elements supplying valuable insights into the development of dynamic user interfaces that seamlessly adapt to the ever-evolving wishes of companies operating inside the inventory management area furthermore it explores how those dynamic interfaces foster a consumer-centric method empowering companies to efficiently navigate the demanding situations posed via fluctuating stock demands and industry dynamics thereby ensuring sustained operational agility and adaptableness.

An in depth exploration into the nuanced usage of MongoDB within the MERN stack for inventory control structures. The studies meticulously investigates its pivotal position in efficient stock monitoring and optimized purchase operations, presenting a nuanced information of ways MongoDB enhances data control in the tricky methods of stock structures. moreover, it delves into MongoDB's potential to address huge datasets and its robust indexing features, illuminating its importance in streamlining information retrieval and ensuring real-time insights for stock selection-makers. moreover, the research highlights MongoDB's schema-less design, bearing in mind dynamic and flexible data modelling, in the MERN stack, which proves to be instrumental in accommodating numerous stock attributes and evolving business requirements. by means of unraveling those intricacies, the study now not handiest underscores MongoDB's contribution to information performance but also well-known shows its adaptability as a foundational element in shaping the responsive and scalable nature of contemporary inventory control structures.

This complete examination delves into the multifaceted contributions of React in the expansive realm of net-based absolutely genuinely answers specializing in its pivotal feature in enhancing the consumer experience the look at elucidates how

React contributes to intuitive navigation and seamless purchasing cart manage providing an intensive exploration of its profound effect within the tough tactics of stock systems moreover it explores reactjs as a flexible device for growing interactive and dynamic customer interfaces emphasizing its functionality to facilitate real-time updates and responsive format thereby ensuring a fluid and appealing purchaser adventure the research underscores React functionality to foster issue reusability streamlining improvement efforts and fostering a modular form internal stock control systems

A rigorous exploration of the multifaceted contributions of Node.js and its position inside the development of dynamic and responsive internet packages. The take a look at delves into the approaches Node.js complements decision-making methods thru the technology of insightful reviews, supplying an in-intensity exploration of its profound impact within the realm of stock control systems. moreover, it illuminates Node.js's performance in managing giant data hundreds, making sure fast and responsive records retrieval for real-time decision-making. The research emphasizes how Node.js, with its non-blocking off I/O operations, extensively reduces processing delays, taking into consideration seamless get entry to crucial data and empowering stock managers with the agility required in dynamic operational eventualities.

This meticulous review seriously analyzes Bootstrap's profound impact on responsive design and operational efficiency inside web-based programs, emphasizing its position in crafting consumer-centric solutions. The study gives a complete exploration of Bootstrap's multifaceted contributions to the complicated strategies of stock structures, supplying nuanced insights into its profound impact inside this expansive domain. additionally, it underscores Bootstrap's versatility in expediting the development of responsive interfaces, permitting swift model to numerous display sizes and gadgets. The research sheds light on how Bootstrap's standardized components and styling options enhance the general person

experience, fostering consistency and simplicity of navigation within the dynamic context of stock control structures.

Studies dedicated to unraveling the multifaceted benefits supplied by way of the combination of present day net technology, exemplified with the aid of the MERN stack. The observe is going past surface-level evaluation, offering a complete understanding of ways these structures adapt to satisfy evolving organizational wishes in stock management, providing a nuanced exploration of their profound impact. It delves into the collaborative synergy of MongoDB, specific.js, React.js, and Node.js, elucidating how every factor contributes to a holistic and agile framework. The research navigates thru the scalability aspects of the MERN stack, emphasizing its innate potential to seamlessly accommodate growing facts volumes and person demands. additionally, it explores how this flexibility fosters organizational growth through making sure that inventory control systems can efficaciously evolve alongside dynamic enterprise requirements.

An exhaustive exploration delves deep into the complex security elements surrounding online transactions in net-based stock control systems. The study intricately examines the included fee gateways, imparting a whole facts of the multifaceted mechanisms hired to ensure at ease and dependable monetary transactions inside such complicated systems. It meticulously dissects the layers of security protocols, encryption methodologies, and real-time validation strategies embedded within those gateways, illuminating their essential feature in fortifying the economic integrity of on-line transactions inside the dynamic landscape of stock management. moreover, the research extends its scrutiny to the evolving challenges in the cybersecurity region, emphasizing how the ones fee gateways constantly adapt to thwart growing threats and make sure the confidentiality, integrity, and availability of sensitive economic records. In elucidating the intricacies of charge gateway integration, this take a look at now not exceptional underscores their important role in safeguarding transactions however additionally contributes to the

broader discourse on improving the general cybersecurity posture of internet-based totally completely inventory manipulate structures.

This studies significantly evaluates the profound and multifaceted effect of entire internet-based totally without a doubt answers on preference-making techniques internal organizations. The test meticulously analyzes how the mixing of the MERN stack and Bootstrap framework contributes to the overall performance of stock manipulate, providing nuanced insights into how those multifaceted technology inform strategic desire-making techniques within the expansive and complicated realm of stock systems. It sheds mild at the synergies a number of the MERN stack and Bootstrap, highlighting their collective feature in improving desire-making normal performance and strategic insights for powerful inventory control.

TECHNICAL COMPARISON

Language and Framework:

In the improvement of our e-commerce website, we adopted the modern MERN (MongoDB, Express.js, React, Node.js) stack due to its comprehensive capabilities. Utilizing MongoDB for flexible data storage, Express.js for robust server-side applications, React for dynamic front-end experiences, and Node.js for a unified development stack, we crafted a coherent and responsive platform. This selection not only streamlined our development process but also contributed to a more seamless and efficient user experience, surpassing the limitations associated with traditional technologies. Choosing conventional technologies such as PHP with Laravel or CodeIgniter could have presented challenges in achieving a similar level of responsiveness and interactivity. The reliance on server-side rendering might have resulted in extended page loading times and a less dynamic user interface, ultimately impacting the overall user experience.

Database Management:

Implementing mongodb in our e-commerce website gives a honest assessment and capacity to supplement product data conventional relational databases together

with mysql or postgresql can gift challenges in handling unstructured and semi-structured e-commerce statistics mongodbs nosql version permits us to fast adapt to changes in statistics merchandise and patron alternatives selecting a conventional relational database for an e-exchange web site calls for a greater rigid database making it hard to transport between merchandise and categories.

Real-Time Interactivity:

Imposing websockets and technology like graphql in our mern stack drastically superior real-time interactivity on our e-commerce platform customers can now revel in stay updates for inventory modifications pricing updates and interactive factors seamlessly in evaluation relying on ajax for constrained actual-time interactivity as in traditional technologies could have limited our capability to supply a more dynamic and tasty purchasing enjoy the person could have skilled delays and much less responsive interactions impacting consumer pleasure

Front-End Development:

The adoption of React.js for our e-commerce the front-give up delivered about a paradigm shift in how we control and display product facts. The thing-based totally architecture now not best advanced code modularity and maintainability but additionally allowed for the introduction of a particularly interactive and visually attractive user interface.

If we had stuck with traditional front-quit development using jQuery, we might have encountered challenges in handling the complexity of the codebase and imparting a present day, responsive layout. the dearth of a element-based totally structure may want to have led to less scalable and maintainable code.

Responsive Design:

Bootstrap and CSS framework play an crucial position in reaching a robust design of our e-commerce web page and when we select the traditional CSS trouble the presets and widgets supplied with the template will assist you to use multiple widgets create a stable and bendy shape location it takes a number of work and time

to complete the response within the interface this consequences in inconsistencies in equipment and display sizes.

Security Measures:

In response to changing safety threats, we use HTTPS as trendy safety on our e-commerce internet site, along with extra strategies consisting of JSON net Tokens (JWT) and OAuth 2.0, to ensure security and patron pride. state-of-the-art technology substantially improves the overall protection of our platform. As inside the beyond, when counting on preliminary SSL encryption, our e-commerce websites might be extra at risk of threats. protection functions now offer greater protection in opposition to capacity vulnerabilities.

Cloud Computing:

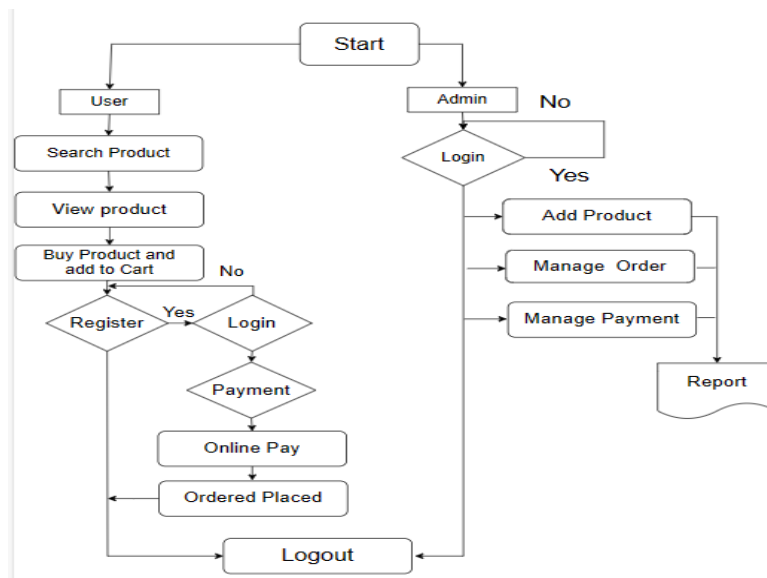

Selecting a cloud device along with aws azure or google cloud to host our e-commerce website lets in us to gain from a fee-powerful answer the strength furnished by using cloud computing enables manipulate green offerings permitting our platform to be tailored to users distinctive desires scalability is the maximum critical aspect if we pick conventional nearby web hosting or traditional server configuration horizontal scaling entities will be less dependable and can motive average performance bottlenecks on height site visitors

Development Workflow:

Using agile methodologies, DevOps practices, and CI/CD pipelines made it easy to improve the overall performance of our e-trade website. This streamlined technique encourages quicker iterations, increases collaboration within the development team, and creates greater impact. If we observe the traditional waterfall design model, consistent growth can inhibit our capacity to quickly adapt to the needs of the business. The agility provided by modern development is essential to remain competitive in a dynamic e-commerce environment.

System Architecture

The contemporary customer journey for acquiring products online is a streamlined and efficient process. It begins with product discovery, typically facilitated by intuitive search functions and categorized browsing experiences. Customers actively seek desired items using keywords or explore relevant categories presented by the online retailer. Once a potential product is identified, a thorough product evaluation phase commences.

This involves meticulously reviewing detailed descriptions, scrutinizing high-resolution images, and carefully assessing specifications to ensure the product aligns with their specific needs and expectations.

Having meticulously evaluated the product and deemed it suitable, customers seamlessly add it to their virtual shopping cart, acting as a temporary holding space for their chosen items. When ready to finalize the purchase, they navigate towards the checkout section. Here, established customers can leverage the convenience of logging in with existing credentials, while new customers can efficiently create accounts for future purchases. Regardless of the chosen path, accurate delivery information must be provided to ensure the seamless and timely arrival of the product.

The final and crucial step involves secure payment processing. Depending on the platform, customers can choose their preferred

method from a selection of secure options, such as credit cards, debit cards, or alternative payment channels offered by the retailer. Upon successful payment confirmation, the online retailer transmits an order confirmation to the customer, outlining the estimated delivery timeframe and providing a unique tracking number for real-time shipment monitoring. With this, the online acquisition journey concludes, leaving the customer to eagerly anticipate the arrival of their coveted purchase.

RESULT

The implementation of the MERN stack and Bootstrap framework in developing our e-commerce website has yielded noteworthy effects. The system effectively manages stock, ensuring actual-time updates and efficient monitoring through MongoDB integration. A person-centric approach and intuitive navigation make a contribution to an more advantageous shopping for enjoy, with streamlined buying facilitated with the aid of integrated charge gateways ensuring cozy on line transactions.

The executive panel, powered via the MERN stack, empowers directors with robust product control, user control, and review moderation abilities. The responsive layout, courtesy of Bootstrap, guarantees a consistent and most excellent person experience throughout devices, promoting accessibility and usefulness. Automation of stock tasks complements operational performance, and the gadget generates insightful reports for informed selection-making.

Scalability and versatility inherent within the MERN stack architecture allow the machine to adapt to changing necessities and accommodate growth. In end, this task effectively leverages cutting-edge technology, demonstrating a sturdy, person-friendly, and efficient e-trade website with the ability for similarly enhancements in the on-line retail landscape.

EMERGING TRENDS IN IT

Ms. Reema.N,

Second Year For It Paavai Engineering College (Autonomous), Pachal, Namakkal-637018

The Department of Information Technology of Paavai Engineering College and The Institution of Engineers (India) jointly organized a one day Guest Lecture on “EMERGING TRENDS IN IT” on 17.04.2023 at Cute Hall. Dr.K. Selvi, Dean Academics, explained the importance of learning computer languages and various opportunities available in IT sector. Mr.D. Saravanan, Walmart Global Tech India, Software Engineers III, Bangalore, as the chief guest. He explained briefly about Information Technology, importance of Information Technology, its types, career in Information Technology and jobs available in coding and non-coding sector. Further he detailed about team structure, regarding the working process of software team, ie. Designing, Developing, support team, and quality. At last he concluded an efficiency of time management and deep learning which is an important protocol professionals.

Ms.N. Reema of second year for IT welcomed the gathering. Faculty members and the students actively participated in the programme and made it a grand success. 100 Participants were really benefited by the guest lecture. In the end K. Swarna of second year IT proposed the vote of thanks.

AGROSAGE CROP PREDICTION USING BIG DATA ANALYTICS: A SYSTEMATIC REVIEW

ABSTRACT

The literature review offers a thorough examination of crop prediction models and agricultural decision support systems, with an emphasis on the combination of machine learning techniques with large data analytics. Various studies focus on leveraging technologies like MapReduce, Naïve Bayes, and support vector machines for precise crop yield predictions in diverse regions, including India and China. The reviewed works also explore weather forecasting, climate-smart agriculture, and the effects of environmental changes on crop productivity. The application of distributed processing, cloud computing, and artificial neural networks in agricultural decision-making support systems is also addressed. Notably, the surveyed papers discuss the significance of features contribution analysis in support vector machines and the utilization of artificial intelligence for rice crop yield prediction. Overall, the literature survey underscores the multifaceted approaches and technologies employed in advancing crop prediction methodologies for enhanced precision and productivity in agriculture.

KEYWORDS

MapReduce, Naïve Bayes, and Support vector machines (SVM), Logistic and Multiple Linear Regression

INTRODUCTION

In the global landscape of agriculture, the effective prediction of crop yields stands as a pivotal challenge with far-reaching implications for food security and resource management. This literature survey embarks on a comprehensive comparison of distinct methodologies employed in crop prediction models, centering around the influential work titled "WB-CPI: Weather-Based Crop Prediction in India Using Big Data Analytics" and relevant reference papers.

Crop prediction models play a critical role in addressing the complexities of agricultural ecosystems worldwide. As the demand for food surges with the expanding global population, optimizing crop prediction becomes imperative. The referenced studies explore diverse strategies, showcasing advancements in precision agriculture. Despite the differences in methodologies, common threads emerge, emphasizing the utilization of sophisticated techniques to harness the vast potential of data analytics in crop prediction.

The cornerstone study, "WB-CPI," shows how weather-based analytics can be integrated for accurate crop forecast. The article, which was co-authored by a team from Manipal University Jaipur and Universiti Tun Hussein Onn Malaysia, presents a multifaceted method for comprehending and forecasting crop behavior. The study's methodology makes use of intelligent technologies and big data analytics to shed light on the intricate interactions between crop development and weather patterns. The papers that are cited offer a variety of viewpoints that add to this discussion. A Naïve Bayes MapReduce precision agriculture model is introduced by

Priya et al., demonstrating the application of distributed computing to crop prediction. Fan et al. emphasize the value of data-driven approaches by shifting the emphasis to big data analytics for crop yield prediction. A study by Ramya et al. explores climate-smart agriculture, which uses big data to adjust to changing climatic conditions. Huang et al. present the China Crop Growth Monitoring System and outline its operational procedures and operations. Support vector machines are used

by Gandhi et al. to forecast rice crop output in India. The overarching goal of this comparative analysis is to dissect the methodologies and algorithms applied across these studies, unraveling their strengths and limitations. Beyond the intricacies of each model, the survey aims to contextualize the findings within the broader scope of global agriculture. As we delve into the complexities of predicting crop yields, it becomes evident that leveraging cutting-edge technologies and interdisciplinary approaches is essential for sustainable and efficient agricultural practices.

Looking forward, the future of agriculture holds tremendous promise. With the continuous evolution of technology, incorporating artificial intelligence, machine learning, and data analytics into crop prediction models can further refine accuracy. Embracing a holistic approach that considers environmental factors, regional nuances, and advanced analytics will be pivotal. This literature survey seeks not only to elucidate the nuances of contemporary crop prediction models but also to pave the way for future advancements that will shape the landscape of global agriculture. In this pursuit, the collective insights from these studies contribute to the ongoing discourse on optimizing agricultural forecasting for a resilient and sustainable future.

LITERATURE REVIEW

The paper [1] introduces an innovative approach to crop prediction in the diverse agricultural landscapes of India. The primary data source for the study is regional agricultural data, which likely includes information on climate patterns, soil characteristics, and historical crop yields specific to the region belts of India. While the specific parameters are not explicitly detailed, it is inferred that essential variables such as climatic conditions, soil properties, and potentially historical crop performance are integral to the precision agricultural model. The crop under consideration is not explicitly mentioned, suggesting the model's adaptability to various crops prevalent in the region belts. Methodologically, the study employs a Naïve Bayes MapReduce approach, integrating the simplicity and effectiveness of

the Naïve Bayes algorithm with the parallel processing capabilities of the MapReduce framework. The Naïve Bayes algorithm, known for its probabilistic classification abilities, is applied to handle complex relationships within agricultural data. The integration with MapReduce allows for parallelized computation, enhancing the model's efficiency in processing large-scale agricultural datasets. While specific tools used in the implementation are not explicitly detailed, the integration with the MapReduce framework implies the adoption of distributed computing technologies, ensuring scalability and efficiency. In essence, the paper contributes significantly to the field of precision agriculture by proposing a model that leverages regional agricultural data, applies a Naïve Bayes algorithm for probabilistic classification, and utilizes the parallel processing capabilities of the MapReduce framework. This approach reflects a holistic methodology for predicting crop outcomes in the varied agricultural contexts of the region belts of India, demonstrating adaptability to different crops and offering potential advancements in precision agricultural practices.

The paper [2] addresses the vital task of predicting crop yields by leveraging big data analytics. The primary data source for this study is not explicitly mentioned, but the title suggests the utilization of large-scale agricultural datasets, likely encompassing factors such as climate, soil conditions, and historical crop performance. The specific parameters considered in the study are not detailed, but it can be inferred that variables influencing crop yield, including climatic factors, soil quality, and potentially other relevant agricultural metrics, are essential components. The crop studied is not explicitly specified, leaving room for flexibility in the model's application to various crops. The methodology of the study focuses on predicting agricultural yield using big data analytics. The algorithm employed for this purpose is not explicitly mentioned, but given the emphasis on big data, it is likely that machine learning or statistical techniques were employed. The tools used for data analysis and processing are not explicitly detailed, but the emphasis on big data

analytics implies the application of technologies and frameworks conducive to handling and analyzing large datasets. In summary, the paper contributes to the field by addressing the challenge of predicting crop yields through the lens of big data analytics. While specific details about the data source, parameters, crop studied, and tools used are not explicitly provided, the emphasis on leveraging big data implies a comprehensive approach to crop yield prediction, potentially incorporating diverse factors and utilizing advanced analytics techniques for improved accuracy in forecasting agricultural outcomes.

The paper [3] addresses the imperative of predicting environmental changes to facilitate the adoption of climate-smart agriculture practices through the lens of big data analytics. The primary data source for the study is not explicitly detailed, but the emphasis on big data suggests the utilization of diverse datasets related to environmental factors, climate patterns, and potentially agricultural variables. The specific parameters considered in the study are not explicitly outlined, but it can be inferred that variables influencing environmental changes and their impact on agriculture, such as temperature, precipitation, and soil conditions, are integral components. The crop studied is not explicitly mentioned, indicating the potential applicability of the proposed methodology to a range of crops susceptible to environmental variations. Methodologically, the paper focuses on the prediction of environmental changes and their implications for climate-smart agriculture, utilizing big data analytics. The specific algorithm employed for this purpose is not

explicitly detailed, leaving room for various machine learning or statistical approaches suitable for analyzing large and complex datasets. The tools used for data analysis and processing are not explicitly mentioned, but the emphasis on big data analytics implies the application of technologies and frameworks conducive to handling and extracting meaningful insights from large datasets. In summary, the paper contributes to the field by addressing the critical need for predicting environmental changes and their influence on agriculture through the application of

big data analytics. While specific details about the data source, parameters, crop studied, and tools used are not explicitly provided, the emphasis on leveraging big data implies a comprehensive approach to understanding the dynamic interplay between environmental factors and agriculture, with the potential for informing climate-smart agricultural practices for a sustainable future.

The paper [4] provides a comprehensive insight into the development and implementation of China's crop growth monitoring system. The primary data source for this study is not explicitly detailed, but the paper focuses on the utilization of remote sensing and geoscience data to monitor crop growth across China. The specific parameters considered in the study include a range of agricultural indicators, such as vegetation indices, land surface temperature, and meteorological data, aiming to capture the multifaceted dynamics of crop growth. While the paper does not explicitly mention a specific crop, it is inferred that the system's methodology is designed to monitor a variety of crops, given the diversity of agriculture in China. Methodologically, the paper introduces a holistic approach to crop growth monitoring, integrating remote sensing techniques, satellite imagery, and ground-based observations. The algorithm employed for data processing and analysis is not explicitly detailed, but it is implied that various remote sensing algorithms and image processing techniques are applied to derive meaningful information about crop growth. The tools used for implementing the monitoring system include remote sensing satellites, ground-based weather stations, and

geospatial information systems (GIS) for data integration and analysis. In summary, the paper significantly contributes to the understanding of China's approach to crop growth monitoring by highlighting the methodology and operational activities of the national monitoring system. While specific details about the data source, parameters, and tools used are not explicitly provided, the emphasis on remote sensing, geoscience data, and integrated monitoring techniques implies a

robust and technologically advanced system designed for monitoring the diverse and extensive agricultural landscapes of China.

The paper [5] explores the integration of big data analytics into precision agriculture with a focus on weather forecasting for optimizing future farming practices. The primary data source for this study is likely diverse and extensive weather datasets, encompassing meteorological variables such as temperature, humidity, precipitation, and wind patterns. Specific parameters considered in the study involve key weather indicators crucial for agricultural decision-making. Although the paper does not explicitly specify the crop studied, it is implied that the research is applicable across various crops, emphasizing a general approach to precision agriculture. Methodologically, the paper delves into the utilization of big data analytics for weather forecasting to enhance precision in agricultural planning. The specific algorithm employed for weather forecasting is not explicitly detailed, but it is inferred that advanced statistical or machine learning techniques suitable for handling large-scale and complex weather data are likely applied. The tools used for implementing the big data analytics framework are not exhaustively detailed; however, the emphasis on big data implies the use of technologies and frameworks conducive to processing and analyzing vast and dynamic datasets. The paper likely considers tools such as Hadoop, Spark, or other distributed computing platforms for efficient data processing. In summary, the paper contributes to the evolving field of precision agriculture by integrating big data analytics into weather forecasting for enhanced decision-making in

future5 farming practices. While specific details about the data source, parameters, crop studied, and tools used are not fully expounded, the emphasis on leveraging big data techniques underscores a forward-looking methodology aimed at optimizing agricultural operations based on accurate weather predictions.

A thorough examination of machine learning methods for crop prediction is provided in the publication [6]. Although the main source of data for this study is

not stated clearly, it is assumed that agricultural datasets with data on soil types, climate, and past crop yields are crucial parts of the analysis. Specific parameters considered in the study encompass a variety of agricultural indicators, including climatic factors, soil quality, and potentially other relevant agricultural metrics crucial for crop prediction. The paper does not explicitly mention a specific crop, suggesting the potential adaptability of the proposed methodology to various crops. The paper's methodology focuses on using machine learning techniques to predict crops; although the precise algorithm isn't disclosed, the broad field of machine learning suggests using statistical or artificial intelligence-based methods that can recognize patterns and make predictions. The tools used for implementing the machine learning model are not explicitly detailed, but the general approach suggests the use of machine learning libraries and frameworks such as scikit-learn or TensorFlow. In summary, the paper significantly contributes to the domain of precision agriculture by introducing a crop prediction system leveraging machine learning techniques. While specific details about the data source, parameters, crop studied, and tools used are not exhaustively provided, the emphasis on machine learning underscores a contemporary and adaptive methodology for enhancing crop prediction accuracy, reflecting the broader trend of incorporating advanced technologies into agricultural practices for improved efficiency and sustainability.

The paper [7] focuses on advancing agricultural yield prediction specifically for rice crops in India through the application of Support Vector Machines (SVM). The primary data source for

this study involves agricultural datasets pertinent to rice cultivation in India, encompassing variables such as climatic conditions, soil properties, and historical crop yields. Specific parameters considered in the study include elements influencing rice crop production, such as temperature, precipitation, and soil characteristics. The crop studied is explicitly identified as rice, signifying a targeted approach to predicting the yield of this staple food crop. The paper's methodology

makes use of Support Vector Machines, a machine learning algorithm well-known for its efficiency in tasks involving regression and classification. The SVM algorithm examines the complex correlations between various elements to generate a prediction model that projects rice crop production. While the paper does not delve into intricate details of the SVM implementation, the algorithm's capability to handle non-linear relationships and high-dimensional data makes it suitable for the complex nature of agricultural datasets. The specific tools used for implementing the SVM model are not explicitly detailed, but it is inferred that machine learning frameworks and libraries supporting SVM implementations are utilized. In summary, the paper contributes significantly to the field of agricultural prediction by leveraging Support Vector Machines to forecast rice crop yields in India. While specific details about the data source, parameters, and tools used are not exhaustively provided, the emphasis on SVM as the predictive algorithm and the targeted study of rice crops underline a focused methodology for enhancing agricultural productivity and sustainability in the context of rice cultivation in India.

The integration of cloud computing and distributed processing technologies in agricultural decision-making support systems is examined in paper [8]. The primary data source for this study involves diverse agricultural datasets, potentially encompassing information related to crop characteristics, soil conditions, weather patterns, and historical agricultural performance. Specific parameters considered in the study likely involve a broad spectrum of agricultural indicators, including climatic

variables, soil quality, and potentially crop-specific metrics. The paper does not explicitly specify a particular crop under investigation, indicating the applicability of the proposed methodology to a range of crops. From a methodological perspective, the paper highlights how agricultural decision support systems can benefit from the use of cloud computing and distributed processing, which can increase the scalability and effectiveness of data processing. Although the exact

algorithm is not stated, the emphasis on distributed processing suggests using parallelized computation, and cloud computing suggests using cloud-based resources for data processing, analysis, and storage. The tools used for implementing the distributed processing and cloud computing framework are not exhaustively detailed, but the general approach suggests the adoption of technologies and platforms that facilitate distributed computing and cloud services, such as Apache Hadoop for distributed processing and cloud platforms like Amazon Web Services or Microsoft Azure. In conclusion, the study advances the field by presenting a cutting-edge technology framework for agricultural decision support systems that makes use of cloud computing and distributed processing. While specific details about the data source, parameters, crop studied, and tools used are not fully expounded, the emphasis on distributed processing and cloud computing underscores a contemporary and scalable approach to handling agricultural data for informed decision-making in diverse and dynamic agricultural environments.

The paper [9] focuses on advancing agricultural yield prediction through the application of Support Vector Machines (SVM) with features contribution analysis. The primary data source for this study involves agricultural datasets, likely encompassing diverse variables related to climate, soil conditions, and historical crop yields. Specific parameters considered in the study include crucial factors influencing agricultural yield, such as temperature, precipitation, soil quality, and potentially other relevant agricultural metrics. While the paper does not explicitly specify the crop studied, it is inferred that the methodology is designed for broad applicability across various crops, given the general nature of agricultural yield prediction. Methodologically, the paper introduces the utilization of Support Vector Machines, a powerful machine learning algorithm, enhanced by features contribution analysis. The SVM algorithm is employed for building a predictive model capable of discerning complex relationships within agricultural datasets. The features contribution analysis allows for the identification of the most influential

factors affecting crop yield. While the specific tools used for implementing the SVM model and features contribution analysis are not explicitly detailed, the general approach suggests the use of machine learning libraries and frameworks supporting SVM, possibly supplemented by statistical analysis tools for features contribution analysis. In summary, by combining features contribution analysis with support vector machines, the paper presents a novel approach that improves our understanding of the factors influencing agricultural yield, making a significant contribution to the field of agricultural prediction. While specific details about the data source, parameters, crop studied, and tools used are not exhaustively provided, the emphasis on SVM and features contribution analysis underscores a sophisticated methodology aimed at improving the accuracy and interpretability of agricultural yield predictions.

The purpose of the paper [10] is to improve rice crop yield prediction by using artificial neural networks (ANN). The primary data source for

this study involves agricultural datasets, likely comprising variables related to climate, soil conditions, and historical rice crop yields. Specific parameters considered in the study include essential factors influencing rice crop production, such as temperature, precipitation, and soil characteristics. The paper explicitly identifies rice as the crop under investigation, emphasizing a targeted approach to predicting the yield of this staple food crop. In terms of methodology, the study describes how to create a predictive model that can identify complex relationships present in agricultural datasets by using Artificial Neural Networks, a machine learning paradigm inspired by the structure and functions of the human brain. While the specific neural network architecture and training methods are not detailed, the use of ANN implies a data-driven approach to learning and predicting rice crop yields. The tools used for implementing the ANN model are not explicitly specified, but the general approach suggests the utilization of machine learning frameworks and libraries supporting artificial neural network implementations. In summary, the

paper significantly contributes to the field of agricultural prediction by leveraging Artificial Neural Networks for accurate rice crop yield forecasting. While specific details about the data source, parameters, and tools used are not exhaustively provided, the emphasis on ANN underscores a contemporary and adaptive methodology for enhancing agricultural productivity, reflecting the broader trend of incorporating advanced technologies into precision farming practices.

METHODOLOGY

Crop prediction and precision agriculture have witnessed a paradigm shift with the integration of advanced technologies and big data analytics. Researchers have explored diverse methodologies to enhance crop yield forecasting, adapting to changing environmental conditions and leveraging computational approaches. In

this context, literature presents a rich tapestry of studies, each contributing unique insights into the domain.

RESEARCH QUESTION

This literature review aims to delve into key research questions that encapsulate the breadth of knowledge in crop prediction, focusing on modeling techniques, geographical variations, environmental adaptation, technology integration, and machine learning applications.

RQ1: What part does the Naïve Bayes MapReduce model play in precision agriculture in the region belts of India for crop pattern prediction?

The Naïve Bayes MapReduce model leverages distributed computing to enhance precision in crop prediction, providing valuable insights for agricultural planning.

RQ2: How does big data analytics facilitate accurate crop yield predictions, and what are the implications for agricultural decision-making?

Big data analytics, as demonstrated in this study, plays a crucial role in predicting crop yields, offering a data-driven approach for informed agricultural strategies.

RQ3: What environmental change predictions are considered for adapting climate-smart agriculture using big data?

The study explores environmental change predictions, utilizing big data to enhance climate-smart agriculture practices for sustainable farming.

RQ4: What methods are employed to monitor crop growth, and what is the operation of the China Crop Growth Monitoring System?

The study provides an overview of crop monitoring in China and provides information on the workings and techniques of the China Crop Growth Monitoring System.

RQ5: How does precision agriculture use big data, especially when it comes to weather forecasting for upcoming farming operations?

The study shows how big data can be integrated into precision agriculture, particularly for weather forecasting, which can lead to improved farming practices in the future.

SEARCH STRATEGY

The search strategy for compiling a comprehensive set of papers on crop prediction and precision agriculture involved a systematic approach across academic databases,

conference proceedings, and relevant journals. The aim was to cover a wide spectrum of research addressing different aspects of crop prediction models, big data applications, and innovative technologies in agriculture. The expanded search strategy is outlined below:

Academic Databases:

Keywords: Utilized a combination of general terms and specific terms related to the field, such as "crop prediction," "precision agriculture," "big data," "machine learning," and "agricultural decision support systems."

Boolean Operators: Employed Boolean operators (AND, OR) to refine searches and include variations of terms, ensuring a comprehensive retrieval of relevant literature.

Google Scholar and ResearchGate:

String Searches: Executed string searches using key phrases and specific algorithm names (e.g., "Naïve Bayes MapReduce," "Support Vector Machines," "Artificial Neural Networks").

Citation Exploration: Explored citations of key papers to identify seminal works and recent developments in the field.

Conference Proceedings:

Conference Names: Targeted prominent conferences in computer science, data science, and agriculture, including but not limited to ICACCI, ISCID, IGARSS, NGCT, JCSSE,

TIAR, and EcoSense.

Conference Websites: Visited conference websites to access proceedings and identify relevant papers presented at these conferences.

Journal Publications:

Specialized Journals: Searched for reputable journals focusing on agriculture technology, data science, and computer science.

Journal Databases: Utilized databases like IEEE Xplore, PubMed, and ScienceDirect to access a variety of journals.

Search Filters:

Publication Year: Applied filters to focus on recent publications (within the last decade) to ensure relevance and incorporate the latest advancements.

Peer-Reviewed Articles: Prioritized peer-reviewed articles to ensure the quality and reliability of the selected literature.

Review Articles and Meta-Analyses:

Included Reviews: Considered review articles and meta-analyses to gain a broader understanding of the existing literature landscape and identify key trends.

Snowballing Technique:

Citation Snowballing: Traced citations backward and forward from key papers to discover related works that may not have been captured through direct searches.

Inclusion and Exclusion Criteria:

Inclusion Criteria: Included papers that demonstrated a focus on crop prediction models, precision agriculture, and the utilization of big data or advanced technologies in agriculture.

Exclusion Criteria: Excluded papers not directly related to the core themes or lacking relevance to the research questions.

A well-rounded collection of literature that together offers a thorough overview of the current state of research in crop prediction and precision agriculture was the

aim of the iterative, expanded search strategy, which was adjusted as new insights were obtained.

STUDY SELECTION

The study selection process involved a meticulous review of research articles focusing on crop prediction and precision agriculture. The initial pool comprised prominent papers presented at conferences and published in reputable journals. The selected papers represent a diverse range of geographical locations, methodologies, and technological applications in the realm of agricultural prediction. Each paper was scrutinized for its contribution to advancing the understanding of crop prediction models, encompassing regions such as India and China, and employing various approaches, including machine learning, big data analytics, and weather forecasting.

DATA EXTRACTION STRATEGY

The data extraction strategy is centered on identifying key elements pertinent to the overarching theme of crop prediction. Extracted information encompassed details on modeling techniques, data sources, geographic considerations, and the incorporation of technological advancements. The subtleties of each paper's methodology – such as the application of artificial neural networks, support vector machines, and MapReduce – were meticulously extracted. Additionally, the data extraction process emphasized the specific contributions of each study to the broader field of precision agriculture, including insights into environmental adaptation, climate-smart agriculture, and the utilization of distributed processing and cloud computing. This comprehensive approach ensured the retrieval of nuanced data essential for synthesizing the collective knowledge embedded in the selected papers.

MODEL SELECTION

Using the ease of use and efficiency of the Naïve Bayes algorithm for classification problems, Priya et al. (ICACCI 2018) suggested a Naïve Bayes MapReduce precision

agriculture model. The requirement for accuracy and scalability in crop production prediction across several agricultural contexts drove the model selection. The MapReduce architecture was used to enable the effective handling of extensive agricultural datasets that are dispersed among several nodes.

Fan et al. (ISCID 2015) concentrated on using big data analytics to forecast agricultural yields. According to the demands of the assignment, they used an approach that includes choosing the right tools, such as statistical models or machine learning algorithms. After handling noise, missing values, and outliers with data pretreatment approaches, feature engineering was used to extract pertinent features from agricultural datasets. Accurate crop yield

projections were ensured by training and assessing the predictive models using appropriate performance indicators.

Predicting environmental changes for climate-smart agriculture was the goal of Ramya et al (IJARCT 2015). They chose predictive modeling strategies that may project future environmental circumstances. To forecast changes in environmental factors important to agriculture, modeling techniques and the study of climate data were used. Thorough testing and comparison with real data were used to verify the precision and dependability of the prediction models.

China Crop Growth Monitoring System was created by Huang et al. (IEEE IGARSS 2011). They used image processing techniques to retrieve pertinent information from satellite pictures and remote sensing devices they had chosen for crop growth monitoring. Crop growth pattern mapping and geographical analysis were made possible by the integration of geographic information systems (GIS). By comparing the monitoring system's results with ground-truth data, its correctness was confirmed.

Bendre et al. (NGCT 2015) concentrated on the application of big data for weather forecasting in precision agriculture. Based on past weather data and meteorological information, they chose suitable big data analytics approaches, including machine

learning algorithms or statistical models, for weather forecasting. The accuracy of weather forecasting models was verified by comparing them with observed weather conditions. Real- time data streams and sensor data were combined for dynamic weather forecasts.

C.S. Sree Dharaneeswari (2023) suggested use supervised machine learning to forecast agricultural production in various soil types. They used soil type data and other pertinent agricultural factors as input features for model training, and they carefully chosen supervised machine learning methods that were appropriate for regression tasks. Model generality over several soil types was validated using cross-validation techniques, and prediction accuracy was assessed by the use of suitable performance criteria.

MODEL TRAINED

Naïve Bayes MapReduce Precision Agricultural Model (Priya et al., ICACCI 2018): The MapReduce architecture is used in the model training methods to handle agricultural data in parallel. To guarantee data quality, the dataset containing agricultural information such crop characteristics, soil type, and climate is first preprocessed. Consequently, because of its ease of use and efficiency in classification tasks, the Naïve Bayes method is chosen. Naïve Bayes is then linked with the MapReduce framework to effectively manage distributed computing. The training portion of the dataset is utilized to train the model, while the testing subset is kept separate. The MapReduce paradigm speeds up the training process by enabling parallel processing of data across numerous nodes during the training phase. The training subset is used to train the Naïve Bayes model, where probability estimates and feature extraction are carried out concurrently across the dispersed nodes. Following model training, the testing subset is used to gauge how well the trained model predicts crop yields. Through testing and comparison with other methods, the model's scalability and efficacy in managing huge agricultural datasets are confirmed.

Big Data Analytics for Crop Yield Prediction (Fan et al., ISCID 2015): Crop yield prediction using big data analytics techniques is part of the model training process. To assure data quality, the dataset comprising agricultural factors like crop characteristics, weather, and soil attributes is first gathered and preprocessed. Relevant characteristics are extracted from the dataset using feature engineering techniques. Support vector machines, random forests, decision trees, and other machine learning algorithms are among the statistical models that are taken into consideration during training. The training portion of the dataset is utilized to train the model, while the testing subset is kept separate. In the training phase, the model parameters are tuned to reduce prediction errors, and the chosen method is trained using the training subset. To evaluate the trained model's generalization performance, cross validation methods like k-fold cross-validation can be used. Accuracy, precision, recall, and F1-score are among the suitable assessment measures that are used to assess the performance of the trained model. Iterative changes are made to the model's parameters and feature selection strategies throughout the training phase in order to increase prediction accuracy.

Environment Change Prediction for Climate- Smart Agriculture (Ramya et al., IJARCT 2015): The process of creating predictive models for predicting environmental changes pertinent to climate smart agriculture is known as the model training approach. To find trends or patterns in historical climate data, climate data analysis approaches are used. For model training, statistical models or machine learning methods such neural networks, regression analysis, and time series analysis are chosen. The training portion of the dataset is utilized to train the model, while the testing subset is kept separate. The chosen model is trained using the training subset during the training phase, where model parameters are adjusted to precisely reflect environmental dynamics. The testing subset is used to validate the training model and evaluate its prediction ability. Prediction accuracy is measured using model assessment metrics including coefficient of determination (R-squared), mean

squared error (MSE), and root mean square error (RMSE). Thorough testing and validation against real-world environmental data are used to evaluate the trained model's resilience and dependability.

China Crop Growth Monitoring System (Huang et al., IEEE IGARSS 2011): Using satellite images and remote sensing, a crop growth monitoring system is developed as part of the model training technique. First, preprocessed satellite photos are gathered, showing crop growth patterns and vegetation indices. Techniques for processing images, including feature extraction, segmentation, and classification, are used to retrieve pertinent data on crop health and development phases. For model training, statistical models like decision trees or support vector machines, or machine learning methods, are chosen. The training portion of the dataset is utilized to train the model, while the testing subset is kept separate. In order to properly categorize crop growth phases, the chosen model is trained using the training subset during the training phase. Model parameters are then optimized. To evaluate the trained model's effectiveness in crop growth tracking, the testing subset is used for validation. To measure classification performance, model assessment criteria including accuracy, precision, recall, and F1- score are used. Through comparison with other methods and validation against ground-truth data, the efficacy and dependability of the trained model are evaluated.

Big Data in Precision Agriculture for Weather Forecasting (Bendre et al., NGCT 2015): Using big data analytics approaches, the model training methodology creates predictive models for weather forecasting in precision agriculture. Preprocessed historical meteorological data is gathered and includes variables like temperature, humidity, precipitation, and wind speed. To extract pertinent characteristics from the meteorological data, feature engineering approaches are used. For model training, statistical models or machine learning methods such neural networks, regression analysis, and time series analysis are chosen. The training portion of the dataset is utilized to train the model, while the testing subset is kept separate. The

chosen model is trained using the training subset in the training phase, when model parameters are adjusted to best represent temporal patterns and dependencies in the meteorological data. The testing subset is used to validate the training model and evaluate its prediction ability. Prediction accuracy is measured using model assessment metrics such mean absolute error (MAE), mean squared error (MSE), or root mean square error (RMSE). Through thorough testing and validation against real-world weather data, the trained model's resilience and dependability are evaluated.

Crop Yield Prediction in Different Soil Types Using Supervised Machine Learning (C.S. Sree Dharaneeswari 2023): Using supervised machine learning approaches, the model training process creates predictive models for agricultural production prediction across various soil types. Datasets including historical crop yields, climatic circumstances, and soil properties are first gathered and preprocessed. To find pertinent variables influencing crop yields, feature selection approaches including correlation analysis, wrapper methods, or embedding techniques are used. Models are trained using supervised machine learning methods including gradient boosting machines, decision trees, random forests, and linear regression. The training portion of the dataset is utilized to train the model, while the testing subset is kept separate. The chosen model is trained using the training subset during the training phase, where model parameters are adjusted to reduce prediction errors. To evaluate the trained model's generalization performance, cross-validation methods like k-fold cross validation are used. Using suitable assessment measures, such as mean absolute error (MAE), of determination (R-squared), the performance of the trained model is assessed. Through thorough testing and validation against real agricultural yield data, the trained model's resilience and dependability are evaluated.

RESULT AND DISCUSSION

The chosen papers offer a thorough summary of various approaches and technological applications related to precision agriculture and crop prediction.

Priya et al. (2018): Presented the Naïve Bayes MapReduce the precision agricultural model for crop forecasting in India's region belts. The application of advanced computing methods to improve agricultural forecasting accuracy is covered in this paper.

COMMON THEMES:

A common theme among the papers is the integration of cutting-edge computing techniques, such as artificial neural networks, machine learning, and big data analytics

Emphasis on the importance of environmental considerations and climate-smart agriculture for sustainable crop prediction.

Numerous studies demonstrate the use of distributed processing, cloud computing, and systematic monitoring for efficient decision-making in agriculture.

Collectively, these papers contribute valuable insights and methodologies to the evolving field of precision agriculture, showcasing the interdisciplinary nature of research in crop prediction and agricultural technology.

CONCLUSION

THEORETICAL IMPLICATIONS

The papers that are cited together highlight the theoretical ramifications of incorporating cutting-edge technologies like cloud computing, big data analytics, and machine learning into the precision agriculture space. These technological integrations provide a foundation for developing sophisticated models and systems

for crop prediction. The emphasis on environmental change prediction and climate-smart agriculture in the literature suggests a theoretical shift towards incorporating ecological factors into agricultural models. Theoretical frameworks are evolving to consider the dynamic interactions between climate, environmental changes, and crop outcomes. The papers contribute to the theoretical underpinning of data-driven decision-making in agriculture. Utilizing cloud computing and distributed processing demonstrates how real-time, data-driven insights can improve agricultural decision-making processes.

LIMITATIONS

One common limitation is the dependency on data quality and availability. The effectiveness of predictive models is contingent on the availability of high-quality data, and limitations in data accessibility could impact the reliability of predictions. The theoretical frameworks presented may face challenges in generalizing across diverse agricultural contexts. Models developed for specific regions or crops might not be directly applicable to different agricultural settings, necessitating careful consideration of contextual factors. Theoretical frameworks often overlook the socio-economic dimensions of agriculture. Limitations arise in addressing how socio-economic factors, such as farmer practices and economic constraints, interact with technological interventions in precision agriculture.

FUTURE AVENUE FOR RESEARCHERS

Future research can delve into enhancing the explainability of machine learning models in crop prediction. Developing models that provide transparent insights into decision-making processes will foster greater trust and adoption among end-users. There is a need for theoretical frameworks that dynamically adapt to climate change scenarios. Future research could explore how predictive models can be designed to continuously learn and adjust in response to evolving environmental conditions. The integration of interdisciplinary perspectives, including agronomy, economics, and

sociology, could form the basis for more holistic theoretical frameworks. Collaborative research across diverse domains can lead to comprehensive models that consider the multi- faceted nature of agriculture.

In summary, while the current literature provides a strong foundation for the integration of advanced technologies into agriculture, addressing limitations and exploring new theoretical avenues will be crucial for the continued advancement of precision agriculture research.

ACKNOWLEDGMENT

The authors express gratitude to the contributors of the referenced papers for their valuable insights in precision agriculture and crop prediction. Their work significantly contributes to the understanding of advanced technologies in agriculture. The field of agricultural research is made richer by the diverse perspectives and methodologies that have been presented. The collaborative efforts reflected in these papers enhance the collective knowledge base and inspire further exploration in the domain.

ABSTRACT

This paper presents a real-time detection system for road violence using deep learning and simulation tools. By integrating single-frame image data with deep learning algorithms, the study develops a robust detection system capable of identifying instances of road violence, such as aggressive driving, road rage, and pedestrian accidents. Results demonstrate the effectiveness of the proposed system in providing timely alerts and facilitating rapid response measures to mitigate the impact of road violence on public safety. This study investigates driver behavior analysis using computer vision and simulation techniques. By analyzing single-frame images captured during simulated traffic scenarios, SUMO (Simulation of Urban MObility) or VISSIM (Visual Interactive Simulation System for Transport) the research examines driver responses to various stimuli and environmental conditions. Findings reveal insights into the factors influencing driver behavior, such as traffic congestion, road conditions, and weather effects, thereby informing the development of interventions to promote safer driving practices and reduce the incidence of road violence.

ABSTRACT

In modern society, the use of social networks is more than ever and they have become the most popular medium for daily communications. Twitter is a social network where users are able to share their daily emotions and opinions with tweets. Sentiment analysis is a method to identify these emotions and determine whether a text is positive, negative, or neutral. In this article, we apply four widely used data mining classifiers, namely K-nearest neighbor, decision tree, support vector machine, and naive Bayes, to analyze the sentiment of the tweets. The analysis is performed on two datasets: first, a dataset with two classes (positive and negative) and then a three-class dataset (positive, negative and neutral). Furthermore, we utilize two ensemble methods to decrease variance and bias of the learning algorithms and subsequently increase the reliability. Also, we have divided the dataset into two parts: training set and testing set with different percentages of data to show the best train-test split ratio. Our results show that support vector machine demonstrates better outcomes compared to other algorithms, showing an improvement of 3.53% on dataset with two-class data and 7.41% on dataset with three-class data in accuracy rate compared to other algorithms. The experiments show that the accuracy of single classifiers slightly outperforms that of ensemble methods; however, they propose more reliable learning models. Results also demonstrate that using 50% of the dataset as training data has almost the same results as 70%, while using tenfold cross-validation can reach better results.

INTRODUCTION

Social networks (SNs) are becoming increasingly popular platforms among people all across the world, and nowadays they are utilized even more than ever. With the growth of SNs like Twitter and increasing their popularity, people share more personal emotions and opinions about various issues in such networks. This rapid growth of SNs, combined with the accessibility of a large amount of data on a multi- tude of topics, provides a great research potential for a wide range of applications, such as customer analysis, product analysis, sector analysis and digital marketing (Bhatnagar and Choubey 2021; Fatehi, et al. 2022). In addition, identifying users' polarities and mining their opinions shared in

various areas, especially SNs, have become one of the most popular and useful research fields. Social media platforms are able to build rich profiles from the online presence of users by tracking activities such as participation, messag- ing, and Web site visits (Cui, et al. 2020). By an increased growth in the number of users in the SNs and subsequently exponential rise in the interactions between them, large vol- umes of user-generated content are produced. It is difficult to analyze all these data since most of the social media data are unstructured and dynamic data which frequently alters. Social network analysis provides innovative techniques to analyze interactions among entities by emphasizing on social relationships (Kumar and Sinha 2021). Nowadays, analyzing SNs with data mining and machine learning algo- data. Data mining is the process of extracting and identifying useful patterns and relationships from piles of data sets that may lead to the extraction of new information by using data analysis tools (Keyvanpour, et al. 2020).

Among different SNs, twitter is one of the most stud- ied SNs for social networks' research. Twitter is a SN that enables users to share their daily emotions and opinions. It is considered a convenient platform for users to share personal messages, pictures, and videos. One of the main advantages of platforms like twitter is that users are organized in these platforms, making this possible to investigate groups of

people or communities who are united by common interests, rather than individual profiles. Furthermore, this is possible through extensive use of hashtags, mentions, and retweets that form a complex network, which can provide us with a rich source of data to analysis. Twitter is known to be a novel source of data for those studying attitudes, beliefs, and behaviors of consumers and opinion makers (Islam, et al. 2020; Kwak and Grable 2021).

Among all various forms of communications, text messages are considered one of the most conspicuous forms, since users can express their opinions and emotions on various and diverse topics using text. Text mining is the process of exploring and transforming unstructured text data into structured data to find meaningful insights. It is defined as a multi-purpose research method to study a wide range of issues by systematically and objectively identifying characteristics of large sample data. Text mining is a sub-field of data mining and an extension of classical data mining methods, which can be applied when making sophisticated formulations using text classification and clustering procedures (Yang, et al. 2021). Hossny, et al. 2020 listed the key challenges for analyzing the text on Twitter including the tweet's length, frequent use of abbreviations, misspelled words and acronyms, transliterating non-English words using Roman scripts, ambiguous semantics and synonyms.

Information in several social media platforms, like blogs, reviewing SNs, and Twitter, is being processed for extracting people's opinions about a particular product, organization, or situation. The attitude and feelings comprise an essential part in evaluating the behavior of an individual that is known as sentiments. These sentiments can further be analyzed using a field of study, known as sentiment analysis (SA) (Singh, et al. 2021). SA belongs to the area of natural language processing (NLP) (Chen, et al. 2020) and it has been an active research topic in NLP, which is a cognitive computing study of people's opinions, sentiments, emotions, appraisals, and attitudes toward entities such as products, services, organizations,

individuals, issues, events, topics, and their attributes (Dai, et al. 2021). Also, it aims to analyze and extract knowledge from the subjective information published on the Internet (Basiri, et al. 2021). Sentiment analysis of user-generated data is very useful to know the opinion of the crowd. Two main approaches for sentiment analysis of text documents are described in the literature, specifically approaches based on machine learning and approaches based on symbolic techniques. Symbolic techniques use lexicons and other linguistic resources to determine the sentiment of a given text. Some research has used machine learning for classifying the sentiment of a given text, sometimes following the approach of most symbolic techniques and seeking to identify positive, negative and neutral categories, but sometimes also considering other sentiment categories such as anger, joy and sadness (Moutidis and Williams 2020).

The SA plays significant role in many domain by extracting the people's emotions which then assist business industry to be developed accordingly. In this study, we investigate the performance of different ML models to analyze the sentiment of two real datasets.

So, the contributions in this paper are summarized as follows:

We generate and preprocess two real datasets extracted with Twitter Application Programming Interface (API)—binomial and polynomial—to investigate the sentiment analysis. Binomial dataset incorporating two polarities of positive and negative which is the typical dataset used in the literature, polynomial dataset, however, includes three positive, negative, and neutral polarities.

We investigate the performance of sentiment classification in terms of accuracy/AUC and accuracy/kappa for four classifiers on both binomial and polynomial datasets, respectively.

To increase the reliability of SA and reduce variance and bias of learning models, we apply ensemble methods on both the binomial and polynomial datasets and then report the accuracy values for these methods.

To find out the best train–test split ratio in addition to K-fold cross-validation, we divide the dataset into two parts: training set and testing set with different percentages of data.

The rest of this paper is structured as follows: Sect. 2 reviews some of the related works in the literature. A description of the methodology that includes data collection, preprocessing for sentiment analysis, sentiment detection, and classification modelling is presented in Sect. 3. The results are presented and discussed in Sect. 4, and eventually, the conclusion is detailed in Sect. 5.

RELATED WORK

Researchers in the field of sentiment analysis have been mostly used supervised machine learning algorithm for primary classification, such as the work done by Chauhan et al. (2020). Furthermore, many of the recent studies use Twitter as the primary source of data (Al-Laith, et al. (2021), Yadav, et al. (2021)).

Henríquez and Ruz (2018) used a non-iterative deep random vectorial functional link called D-RVFL. They analyzed two different datasets. Dataset 1 contains a collection of 10,000 tweets from the Catalan referendum of 2017 and dataset 2 contains a collection of 2187 tweets from the Chilean earthquake of 2010. They consider the datasets as a two-class classification problem with the labels of positive and negative. By the use of D-RVFL, results show the best performance compared to SVM, random forest, and RVFL. Ankit and Saleena (2018) proposed an ensemble classification system formed by different learners, such as naive Bayes, random forest, SVMs, and logistic regression classifiers. Their system employs two algorithms: the first algorithm calculates a positive and a negative score for the tweet, and the second algorithm utilizes these scores to predict the sentiment of that tweet. Furthermore, the dataset consists of

43,532 negative and 56,457 positive tweets.

Symeonidis et al. (2018) evaluated the preprocessing techniques on their resulting classification accuracy and the number of features they produce. However, this

paper worked on lemmatization, removing numbers, and replacing contractions techniques, while the detection accuracy is low. For this task, they used four classification algorithms named logistic regression, Bernoulli Naive Bayes, linear SVC, and convolutional neural networks on two datasets with the classes of positive, negative, and neutral.

Sailunaz and Alhajj (2019), used a dataset to detect senti- ment and emotion from tweets and their replies and meas- ured the influence scores of users based on various user- based and tweet-based parameters. The dataset also includes replies to tweets, and the paper introduces agreement score, sentiment score and emotion score of replies in influence score calculation.

Ruz, et al. (2020), reviewed five classifiers and assessed their performances on two Twitter datasets of two different critical events. Their datasets were Spanish, and they con- cluded that there is no difference between the behavior of support vector machine (SVM) and random forest in English and Spanish. In order to automatically control the number of edges supported by the training examples in the Bayes- ian network classifier, they adopt a Bayes factor approach, yielding more realistic networks.

Wang et al. (2021) proposed a system for general popula- tion sentiment monitoring from a social media stream (Twit- ter), through comprehensive multilevel filters, and improved latent Dirichlet allocation (LDA) method for sentiment clas- sification. They reached an accuracy of 68% for general sen- timent analysis using real-world content. Also, they used a dataset with three categories (positive, negative, and neutral) and a dataset with four categories (positive, negative, neutral and junk).

Ali et al. (2021) utilized the bilingual (English and Urdu) data from Twitter and NEWS websites to do the sentiment and emotional classification using machine learning and deep learning models. Kaur and Sharma (2020) used API to

collect beneficial-related corona virus tweets and then categorized them in three groups (positive, negative, and neutral) to investigate the feeling of people about the COVID-19 pandemic. Nuser et al. (2022) proposed an unsupervised learning framework based on serial ensemble of some hierarchical clustering methods for sentiment analysis on a binomial dataset collected from Twitter.

Machuca et al. (2021) used English COVID-19 pandemic tweets to do the sentiment analysis using a logistic regression algorithm on a binomial dataset including positive and negative labels.

In Table 1, we present a review of the state-of-the-art and their reported accuracy for the sentiment classification with data structures of binomial (positive and negative) and polynomial (positive, negative, and neutral).

Methodology

This section introduces our research framework in four phases: data collection, preprocessing, sentiment detection, and classification modeling (Fig. 1).

Data collection

Twitter is among the most popular social networking platforms nowadays. It provides its users with a platform to share their daily lives with other users and express their opinions about different national, international issues from various perspectives. Every user can write a short text called tweet with a maximum length of 140 characters. These opinions and comments can be used to raise public awareness to help the government and enterprises understand the views of the public. Twitter also can be used to predict event trends. Therefore, tweets are an important resource to study public awareness.

Researchers and practitioners can access Twitter data using Twitter API. Search and streaming APIs allow them to collect Twitter data using different types of queries, including keywords and user profiles, which has offered them opportunities to access the data needed to analyze challenging problems in diverse domains. Thus, many researchers and practitioners have begun to focus on Twitter data mining to obtain more research value and business value from this research (Li et al. 2019).

For our experiments, in order to collect tweets, we selected a few recent events and issues; search keywords about corona virus like #covid-19, #coronavirus. For our experiments, in order to collect tweets, we selected a few recent events and issues; search keywords about corona virus like #covid-19, #coronavirus, #covid19vaccine, etc. A total of 14,000 tweets were extracted using Twitter API. 6980 of which were written in English; therefore, we picked these tweets. These tweets were sentences; consequently, we had to preprocess these sentences and convert them to a set of words. Then, these words were classified to be understood by the classifier. In the following sections, we elaborate the mentioned procedure.

Preprocessing

Tweets are sometimes not in a usable format, for instances they include characters, symbols or emoticons. Therefore, we need to format them in an appropriate usable form to be able to extract meaningful opinions from them. As a first step in preprocessing, most (if not all) studies apply tokenization. Tokenization is a task for separating the full text string into a list of separate words. Tokenization is defined as a kind of lexical analysis that breaks a stream of text up into words, phrases, symbols, or other meaningful elements called tokens. At its core, the process of tokenization is a standard method for further natural language processing

(NLP) transformation in preprocessing (Symeonidis, et al. 2018). For the preprocessing steps, various methods have been proposed and can be applied for data cleaning. Following are the steps in the data preprocessing that we used in this article:

All non-English tweets are eliminated.

User names preceded by '@' and external links are omitted.

All hashtags (only the # symbol) are removed.

Stop-words or useless words are removed from the tweet.

All emoticons were removed (i.e., :-), :-(etc.).

All the tweets were converted to lower case to make the dataset uniform.

Detection

Each tweet should be labeled with sentiment with three possible values: negative, neutral, or positive. The first step to label the tweets is to apply unsupervised methods due to the large dataset we have. For this purpose, we used the Text- Blob library in the python programming language to label tweets. This library assigns each tweet a number between

- 1 and + 1 (-1 is the most negative and + 1 is the most positive value). Then, we double-checked the labels manually. Tweets between $[-1, -0.1]$, $[-0.1, +0.1]$ and $[+0.1, +1]$ were labeled negative, neutral, and positive, respectively. Figure 2 illustrates the results from the sentiment analysis. Also, the number of tweets in each class is shown in Table 2. We have a total of 6980 tweets: 977 of which are negative, 3689 of which are neutral and positive tweets are 2314.

Classification modelling

For our experiment and in order to make a comparative analysis, we employed four classifiers, which are the most widely used classifiers for sentiment analysis, namely (1) K-nearest neighbor (KNN), (2) decision tree (DT), (3) support vector machine (SVM), (4) Naive Bayes (NB), and also two ensemble methods including voting and bagging.

K-nearest neighbor

The logic behind KNN classification is that we expect a test sample X to have the same label as the training sample located in the local region surrounding X denoting by K . Training a KNN classifier simply consists of determining K . KNN simply memorizes all samples in the training set and then compares the test sample with them.

Decision tree

The decision tree is a particularly efficient method of producing classifiers from data. It is a tree-like collection of nodes intended to create a decision on values affiliation to a class or an estimate of a numerical target value. Each node represents a splitting rule for one specific attribute. For classification, this rule separates values belonging to different classes. The building of new nodes is repeated until the stopping criteria are met. A prediction for the class label attribute is determined depending on the majority of examples which reached this leaf during generation.

Support vector machine

An SVM is a supervised learning algorithm creating learning functions from a set of labeled training data. Support vector machine solves the traditional text categorization problem effectively. The main principle of SVMs is to determine a linear separator that separates different classes in the search space with a maximum distance. SVM's classification function is based on the concept of decision planes that define decision boundaries between classes of samples. The main idea is that the

decision boundary should be as far away as possible from the data points of both classes. There is only one that maximizes the margin.

Naive Bayes

The naive Bayesian method is one of the most widely used methods for text data classification. The naive Bayesian is a simple probabilistic classifier that uses the concept of mixture models to perform classification. The mixture model relies on the assumption that each of the predefined classes is one of the components of the mixture itself. The components of the mixture model denote the probability of belonging-ness of any term to the particular component. Naive Bayes classifier uses the concept of Bayes theorem and finds the maximum prospect of the probability of any word fitting to a particular given or predefined class. This algorithm assumes that the elements in the dataset are independent from each other and their occurrences in different datasets indicate their relevance to certain data attributes (Desai and Mehta 2016). This method is a high-bias, low-variance classifier, and it can build a good model even with a small data set. Typical use cases involve text categorization, including spam detection, sentiment analysis, and recommender systems.

Ensemble methods

Ensemble methods are learning algorithms which try to improve the predicted performance by employing a set of learning algorithms. They reduce bias and variance of the model and so are more reliable compared to the single classifier (Dietterich 2000). The voting method can be used with different combination sets of the classifiers; therefore, we applied the voting method with the combination set of all classifiers to get the maximum value for accuracy. We also used the bagging method with DT (generally this amalgamation has shown a better performance) and bagging with SVM, KNN, and NB.

Evaluation metric

Accuracy

$$\text{accuracy} = \frac{TP + TN}{TP + TN + FP + FN}$$

$$TP + TN + FP + FN$$

TP, TN, FP, and FN are the number of true positive, true negative, false positive, and false negative.

AUC The area under the curve (AUC) is the measure of the ability of a classifier to distinguish between classes and is used as a summary of the receiver operator characteristic (ROC) curve. The higher the AUC, the better the performance of the model at distinguishing between the positive and negative classes.

Kappa Kappa is a metric that provides a comparison between observed accuracy and expected accuracy.

To start the classification, we divided the dataset into a training set and a testing set with different percentages of data. Common ratios used are 70% or 60% of the dataset for training and 30% or 40% for testing. In our experiment, we used different train-test split percentage, which are 10% to 70%. Continuing the classification, we also used K-fold cross-validation (K-FCV) with $K = 10$ to generate the training set and the testing set and compare the results with above-mentioned split ratios.

In this paper, first, the above-mentioned classifiers were applied to a dataset with just negative and positive tweets (binomial), and then, the classifiers were applied to a dataset including negative, positive, and neutral tweets (polynomial).

Result analysis

This section gives an overview of the accuracy rates of different trained classifiers. All the calculations are done in the RapidMiner Studio application.

Table 3 shows the predicted accuracy of all classifiers when the tweets are binomial. Our results in Table 3 demonstrate that K-FCV with $k = 10$ has the highest accuracy rate, except DT, besides the accuracy when we use the train-test split procedure. SVM with 86.42% in single methods and voting with 86.75% in ensemble

methods has the best accuracy rates. In Table 4, we can see the differences between the accuracy rates. In most algorithms, there is some decrease in accuracy rate when we used 60% of the dataset for training data. Also, this decrease can be seen when 40% of the dataset is used for training in some methods. Furthermore, in all methods when the ratio is 20%, there is the most increase in accuracy rate in comparison with the ratio of 10%. NB

algorithm with + 9.15% and bagging with NB with + 9.62% have the most variation in accuracy rate from 10 to 70% train–test split percentages of the dataset.

Table 5 shows the predicted AUC for binomial dataset. SVM and bagging with SVM have the best values. We can also see that the 10-FCV has better results than the

split procedure. From Table 6, the results show that there is some reduction when we use 60% of the dataset for training data than 50%. An increase in AUC from 10 to 20% of the dataset is more than other ratios.

The classification continued with the polynomial dataset. So we applied classifiers to the dataset with three categories including positive, negative, and neutral tweets. Tables 7, 8, 9, 10 show the comparison between classifiers in terms of accuracy and kappa metrics when the tweets are polynomial. According to Tables 7, 8, 9, 10, there is some reduction in accuracy and kappa rates when we use 60% of the dataset for training data than 50% in most classifiers, and in some cases we have just a little increase in the accuracy and kappa rates. SVM and bagging with SVM have better results compared to other classifiers. SVM with an accuracy of 73.91%

is the better choice for polynomial classification. However, the bagging with SVM is a more reliable model compared to SVM, employing the ensemble method. This technique makes the learning model more reliable by reducing variance and bias. Tables 7 and 10 show that the most positive variation has happened from 10 to 20% of the dataset in both accuracy and kappa terms.

From the results of accuracy and AUC on the binomial dataset (Tables 3, 4, 5, 6) and the results of accuracy and

kappa on the polynomial dataset (Tables 7, 8, 9, 10), we can observe that SVM and bagging with SVM have better results

compared to other classifiers. However, the accuracy of polynomial classification is less than binomial. The reason of over-performing of SVM can be the fact the text data have a sparse nature. In such type of data, there are few irrelevant features that tend to have a correlation with each other. This leads those features to turn into some distinct categories, which can be separated by linear separators. Also, we can see most of the classifiers in 50% train–test split percentage have almost the same results

as 70% in accuracy (Figs. 3 and 4), AUC and kappa rates, while using 10-FCV can reach better results.

Fig. 3 Classification accuracy on binomial dataset

Fig. 4 Classification accuracy on polynomial dataset

We also compared the performance of SVM, when 10-FCV is imposed, with state of the art presented in Table 1. The results showed that overall accuracy has improved at least 3.52% and 5.91% on binomial and polynomial datasets, respectively. This improvement can be a result of using the training and testing data divided through the K-fold cross-validation method.

CONCLUSION

In this paper, we aimed to analyze the sentiment of social media data, specifically Twitter, using both single classifiers and ensemble models combined with single classifiers on two datasets including binomial (positive and negative) and polynomial (positive, negative, and neutral) datasets.

From the results, we observed that data mining is a good choice for sentiment prediction since the accuracy rates are relatively high values. We also reviewed four classifiers, including SVM, K-nearest neighbor, decision tree and naive Bayes and two bagging ensemble methods.

From the results, we concluded that among single classifiers and their combination with the ensemble methods, SVM reached 3.53% and 7.41% over performances on binomial and polynomial datasets, respectively. Although ensemble methods do not show over performance compared to single methods, they are able to decrease the bias or variance of the learning models and also decrease the generalization error. Therefore, there is a trade-off between reliability of the algorithm and accuracy.

Our results show that using 50% of the dataset as training data has almost the same results as 70%; however, using 10-FCV has better results. This conclusion can be seen both in the accuracy and AUC rates in the binomial dataset and accuracy and kappa rates in the polynomial dataset.

In future studies, we will apply other ensemble methods, such as boosting and stacking combined with other classifiers, along with single classifiers. Furthermore, we will attempt to improve our dataset by selecting other keywords including both negative and positive sentiments and increasing the size of the dataset by extracting more tweets.

ABSTRACT

The key problem in human behaviour recognition is how to build a spatiotemporal feature extraction and classification network. Aiming at the problem that the existing channel attention mechanism directly pools the global average information of each channel and ignores its local spatial information, this paper proposes two improved channel attention modules, namely the space-time (ST) interaction module of matrix operation and the depth separable convolution module, combined with the research of human behaviour recognition. Firstly, the behaviour video is segmented, and low rank learning is performed on each video segment to extract the corresponding Low rank behaviour information, and then this Low rank behaviour information are connected on the time axis to obtain the Low rank behaviour information of the whole video, so as to effectively capture the behaviour information in the video, avoiding tedious extraction steps and various assumptions. The method utilizes Multiscale Convolutional Neural Networks (CNNs) to analyze video data and extract hierarchical features indicative of student attention levels. Experimental evaluations demonstrate the effectiveness of the proposed approach in accurately identifying instances of student engagement; facilitating more targeted teaching interventions and classroom management strategies. Experiments on

several public datasets show that the proposed method has a good classification effect. The experimental results show that the method has a good accuracy in human behaviour recognition. It is proved that the proposed model not only improves the recognition accuracy, but also effectively reduces the computational complexity of output weights and improves the compactness of the model structure.

A STUDY ON ANALYSIS OF CONSUMER DECISION MAKING VARIABLES ON ZOMATO IN SALEM CITY

INTRODUCTION TO THE STUDY:

Customer satisfaction is a term frequently used in marketing. It is a measure of how products and services supplied by a company meet or surpass customer expectation. Customer satisfaction is defined as 'the number of customers, or percentage of total customers, whose reported experience with a firm, its products, its services exceeds specified

satisfaction goals. In researching satisfaction, firms generally ask customer whether their product or service has met or exceeded expectations. Thus expectations are a key factor behind satisfaction. When customers have high expectations and there falls short they will be disappointed and will likely rate their experience as less than satisfying.

OBJECTIVES OF THE STUDY:

- To know about the expectation and satisfaction level of respondents towards Zomato.
- To identify the factors influenced for choosing Zomato

SCOPE OF THE STUDY:

Scope of the study is limited towards Respondents who have experienced such online food delivery services through Zomato app. The study is basically conducted to know how consumers perceive the online food delivery services. The expectation and satisfaction of consumers may vary under different circumstances. From this study, we can have a better understanding of the Online Food Delivery Service Market. Therefore, these findings may help the service providers to work upon on these variables to fill up the gaps in the mindset of consumers. Research on the buying behavior which would include brand performance, brand attitudes, product satisfaction, purchase behavior, purchase intentions ,brand awareness segmentation, etc.

RESEARCH METHODOLOGY:

Primary data: To study the customer satisfaction on Zomato a questionnaire was prepared and the data was collected from the respondents who are using Zomato application.

Secondary data: The secondary data was collected with the help of internet search, and online articles.

SAMPLE DESIGN:

The research was carried out in various phases that constituted an approach of working from whole to part. It included several phases which tried to deeper into users likings and

develop a thorough understanding of what the consumer looks forward while ordering food online.

STRUCTURE OF QUESTIONNAIRE:

Questionnaire was divided into two sections. First part was designed to know the general information about customers and the second part contained the respondent's opinions about customer's satisfaction.

PERIOD STUDY:

The duration of study is from March 2024 Which is 20 days study

SAMPLING TECHNIQUES:

Percentage analysis

Research questions are always answered with a descriptive statistic: generally, either percentage or mean. Percentage is appropriate when it is important to know how many of the participants gave a particular answer. Generally, percentage is reported when the responses have discrete categories.

Bar graphs

It is a chart or graph that presents categorical data with rectangular bars with heights or lengths proportional to the values that they represent. The bars can be plotted vertically or horizontally. A vertical bar chart is sometimes called a column chart.

A bar graph shows comparisons among discrete categories. One axis of chart shows the specific categories being compared, and the other axis represents a measured value. Some

bar graphs present bars clustered in groups of more than one, showing the values of more than one measured variable.

Pie Chart

A pie chart is a circular statistical graphic, which is divided into slices to illustrate numerical proportion. In a pie chart, the arc length of each slice is proportional to the quantity it represents.

DATA ANALYSIS AND INTERPERATION:

Gender of the respondent

It is clear that the above table shows 40% of the respondents belong to female finally 60% of the respondent belong to male category.

S.NO	PARTICULARS	PERCENTAGE
1	MALE	60%
2	FEMALE	40%
TOTAL		100%

FINDINGS

- Majority (65%) of the respondents are age between 22-26.
- Majority (60%) of gender respondents are Male.
- Majority (75%) of the respondents are Unmarried.
- Most of the (55%) respondents are Students.
- Majority (21.1%) of the respondents are monthly income is 50,000-1,00,000
- Majority (65%) of the respondents are ordering food through online.
- Majority (40%) of the respondents are Ordering Monthly once.
- Majority (40%) of the respondents are ordering Lunch.
- Majority (60%) of the respondents are easy to understand the language in English.

SUGGESTIONS:

- Company should try to reach to people of other age groups Company should take necessary steps to stimulate customers in repurchasing on a frequent basis.
- Zomato should focus more on other promotional activities such as television advertisements.
- The company should focus on giving better quality product as most customers were very brand loyal and were generally satisfied with the product.
- The company should try to be competitive than other companies and
- Try to establish a strong position in the market.

CONCLUSION

Applications for the food supply have now become a major sensation in India. Numerous food delivery applications in India can be downloaded from the ease of homes on smart phones to order food on the go. The study helped in identifying the factors which influenced the customers for choosing Zomato. On Analyzing the customer satisfaction on Zomato, it can be concluded that the company has to focus on building positive image regarding the product on customer's mind. Customer's expectation about Zomato was surpassed and most of the customers are satisfied in every means. The customers who had several expectations before using Zomato more satisfaction after making purchases. Comparing with other variables customers are more satisfied on the delivery speed of Zomato.

ABSTRACT

Brand awareness is the extent to which consumers are familiar with the qualities or image of a particular brand of goods or services. The consumer's ability to recognize or recall a brand is central to purchasing decision-making. Purchasing cannot proceed unless a consumer is first aware of a product category and a brand within that category. As brands are competing in a highly globalized market, brand awareness is a key indicator of a brand's competitive market performance. Brand awareness is one of the major brand assets that adds value to the product, service or company. Investing in building brand awareness can lead to sustainable competitive advantages, thus, leading to long-term value. Buying behavior is the consumer's attitudes, preferences, intentions, and decisions regarding the consumer's behavior in the marketplace when purchasing a product or service. This study analyses the buying behavior of the customers and their awareness about the brand Samsung and their satisfaction towards the android mobile phones of Samsung.

INTRODUCTION

Brand awareness refers to the extent to which customers are able to recall or recognize a brand. Brand awareness is a key consideration in consumer behavior, advertising management, brand management and strategy development. The consumer's ability to recognize or recall a brand is central to purchasing decision-making. Purchasing cannot proceed unless a consumer is first aware of a product category and a brand within that category. Awareness does not necessarily mean that the consumer must be able to recall a specific brand name, but he or she must be able to recall sufficient distinguishing features

for purchasing to proceed. For instance, if a consumer asks her friend to buy her some gum in a "blue pack", the friend would be expected to know which gum to buy, even though neither friend can recall the precise brand name at the time.

Different types of brand awareness have been identified, namely brand recall and brand recognition. Key researchers argue that these different types of awareness operate in fundamentally different ways and that this has important implications for the purchase decision process and for marketing communications. Brand awareness is closely related to concepts such as the evoked set and consideration set which is Samsung be specific aspects of the consumer's purchase decision. Consumers are believed to hold between three and seven brands in their consideration set across a broad range of product categories. Consumers will normally purchase one of the top three brands in their consideration set.

OBJECTIVES OF THE STUDY:

Primary Objective:

To Study the Brand awareness towards Samsung Mobile in Nammakkal

Secondary Objective:

- To analyze the awareness among the public about Samsung mobile.
- To identify how the public are influenced to buy Samsung mobile.
- To know how the public are aware of the showroom location.
- To find out the public preference for the particular model Samsung mobile.
- To analyze the awareness among the public about Samsung mobile logo and slogan.
- To provide suggestion to create more brand awareness.

Statement of The Problem

The numbers of mobile cellular phone users are increasing day by day in India. Companies make aggressive marketing, advertising and promotional efforts which compel other manufacturers to focus on their marketing efforts as well. These companies resort to price reductions, new function additions, value additions and focus advertising and promotional campaigns. Despite the various systems introduced by each manufacturer, customers are going to face technical problems like network busy problems, improper

coverage, and advertising agencies, poor customer care, improper communication, interruption while speaking with others.

RESEARCH METHODOLOGY:

Definition of research

Defining of and redefining problems, formulating hypothesis or suggested solutions; collecting, organizing and evaluating data; making deductions and reaching conclusions to determine whether they fit hypothesis.

Type of Research:

Descriptive research

Descriptive research includes surveys and fact finding enquires of different kinds. The major purpose of research is Descriptive of the state of affairs as it exists at present.

SOURCES OF DATA:

Primary data

Primary data required for the study is collected by circulating questionnaire among respondents.

Secondary data

Secondary data needed for conducting the research work is collected from various documents & other reports.

SAMPLE SIZE

Total sample size for the research is 50

SAMPLING PROCEDURE:

Sampling technique used for the collection of data required for the research study is multi stage random sampling method.

DATA COLLECTION INSTRUMENT:

The instrument used for data collection is a structurally planned questionnaire.

Tools Used in the Study Percentage analysis

Percentage analysis is the method to represent raw streams of data as a percentage (a part in 100 - percent) for better understanding of collected data. It represents or summarizes the relevant features of a set of values. This can be calculate by this formula

$$\text{Percentage analysis} = \frac{\text{Number of frequency}}{\text{Total Number of frequency}} \times 100$$

Chi-square Test:

The chi-square test is an important test amongst the several tests of significant'. Chi theoretical variance Square, symbolically written as χ^2 , is a statistical measure used in the context of sampling analysis for comparing a variance to a.

$$\text{This can be calculated using the formula } \chi^2 = \sum \frac{(O-E)^2}{E}$$

Where

O = Observed frequency.

E = Expected frequency.

Classification of respondents on the basis of occupation

Occupation	No.of Rrespondents	Percentage
Government employee	10	11.1
Private company employee	30	33.3
Businessman	18	20.0
Farmer	27	30.0
Others	5	5.6
Total	90	100.

Inference From the above table it can be inferred that 11.1% of the respondents were Government employee, 33.3% of them belonging to private company employee, 20% of them belonging to businessman, 30% of them belonging to farmer and the 5.6% of them were others.

Classification of respondents on the basis of occupation

Therefore P Value=0.716, $P > 0.05$, $0.716 > 0.05$, Therefore H0 is ACCEPTED.

Inference

It is evident from the table that the calculate value is more than the table value. Therefore Null hypothesis is accepted. Hence there is no significant relationship between what is the nature of job are indulged in and in your opinion, what could be the most important reason.

FINDINGS:

- Majority of the respondents 48.9% belong to category of 30-40 years of age.
- Majority of the respondents 90% belong to category of male.
- Majority of the respondents 35.6% belong to category of had some UG.
- Majority of the respondents 33.3% have Private company employee.
- Majority of the respondents 51.1% belong to category of live in urban area.
- Majority of the respondents 56.7% have Rs.10000-15000 as income per month.
- Majority of the respondents 50% belong to category of the nature of job indulged in farmer.
- Majority of the respondents 51.1% belong to Samsung. Majority of the respondents 36.7% have the model of compressor.
- Majority of the respondents 96.7% belong to category of yes for recommend your brand of pump to other.
- Majority of the respondents 40% belong to category of the Rectification of field complaints for the services offered by the company preferred are by respondents.
- Majority of the respondents 37.8% belong to category of SAMSUNG brand for fast moving in respondents area.
- Majority of the respondents 46.7% belong to category of low price.
- Majority of the respondents 27.8% belong to category of friends and relatives for respondents got information about it brand of pump

SUGGESTIONS:

For consumers Companies should try to improve awareness about the model like Open-well submersible, Bore- well submersible. Company should improve services like Operational demonstration, Briefing of check lists. Most people have opinioned low price and durability as reason for preference thus, SAMSUNG should focus which are low price

with durability. The company should improve advertisements like radio advertisements, outdoor advertisements. The company should create an interactive website and think about social media marketing.

For Retailer

The Company should try to improve relationship with retailer. The company should offer more profit margin to retailer.

CONCLUSION

The study provides vital information of the company regarding the customer's opinion and their expectation towards the brand. From the study the researcher had identified that the company has to cater to the needs and wants of customer in order to increase the preference level. By innovating on new products and more concentration on electronic items the company can survive in the long run.

INTRODUCTION

Marketing is the process of planning and executing the conception, pricing, promotion, and distribution of ideas, goods, and services to create exchanges and satisfy individual and organizational goals.

Marketing activities should be carried out under the well-thought-out philosophy of efficient, effective, and socially responsible marketing. There are five competing concepts under which organizations can choose to conduct marketing activities. production concept, the product concept, the selling/buying concept, the marketing concept, and the social marketing concept.

The customer is the theme of all business functions. The purpose of business is to create and keep customers. If the customers are not satisfied, a day will come when there will be no customers to do business with. Therefore, the customer should be put at the center of all business activities, cutting across functional and hierarchical boundaries.

The marketing concepts hold that the key to achieving organizational goals and consists of being more effective than competitors in integrating marketing activities towards. Determining and satisfying the needs and wants to target markets.

METHODOLOGY

Research methodology is used to systematically solve research problems. Research methodology is understood as a source of the study of how to research scientifically and the various steps adopted by researchers studying their research problems along with the logic. The project work is entitled A Study on Customer Satisfaction with Sky bags with Special Reference to Buy.

- Sample size
- The sample size in the study is 105.
- Statistical tools
- Simple percentage method
- Chi-square test

PERCENTAGE METHOD

Simple percentage analysis is one of the basic statistical tools that is widely used in the analysis and interpretation of primary data. It deals with the number of respondents responses to a particular question and the percentage that arrived from the total population selected for the study.

$$= \frac{\text{No. of Respondents Percentage}}{\text{Total Respondents}} \times 100$$

CHI-SQUARE TEST

A chi-square test is a statistical test used to compare observed results with expected results. The purpose of this test is to determine if a difference between observed data and expected data is due to chance or if it is due to a relationship between the variables you are studying.

$$\text{Chi-square} = \frac{(O-E)^2}{E}$$

AI – Artificial intelligence, banking, financial services and consumer satisfaction

INTRODUCTION

The ability of a machine to perform cognitive functions we associate with human minds, such as perceiving, reasoning, learning, interacting with the environment, problem solving, and even exercising creativity," is the standard definition of artificial intelligence. But in

reality, artificial intelligence (AI) is really a conglomeration of sophisticated computer technologies at different stages of development.

AI in Financial Services

The financial sector has also seen a number of advancements in the areas of asset management, customer service, recruiting, and communications. For instance, modern banking and stock investment rely heavily on technical know-how and pure luck. However, in the future, we will be able to handle money very differently thanks to algorithms, crowdsourced data, and sentiment analysis.

Major Areas of Artificial Intelligence can be used in banking

- Personalized Financial Services
- Smart Wallets
- Voice Assisted Banking
- Customer support
- Digitalization instead of branch lines
- Reduce Costs
- Mitigate Risk
- Increase Revenue

Different AI application in Banking and Financial Services

Customer Support and Marketing

Chatbots: Chatbots are self-learning programs that communicate intelligently with humans via chat or audio. Although available 24/7 and simple to use, training may be time-consuming.

Robo-Advisors for Financial Products: Robo-Advisors for Financial Products are online systems that use algorithms to provide financial advice, reinvest dividends, and automatically create and rebalance portfolios. This requires little to no human intervention.

Personalized Financial Services: Robo-advisors that track client objectives and make recommendations on which stocks or bonds to purchase or sell; provides individualized care to clients regardless of their tolerance for risk.

Smart Wallets: Mobile wallets with intelligence incorporated for intelligent services like chat, bus ticket, taxi, event, movie, utility bill payment, etc.

Emotion AI: AI can detect human emotions with powerful facial and voice recognition technology.

Security and Compliance:

Fraud Detection and Prevention: Reduce the amount of ongoing labor that is needed to identify and stop security breaches. These platforms automate the process with machine learning.

Compliance Monitoring: Use AI to quickly identify possible problems in long papers by scanning them; otherwise, it would take hours.

Intelligent QRC: A recent subset of artificial intelligence firms focuses on assisting businesses in maintaining compliance; for example, they make sure no document is overlooked while filing, and they mitigate risk by tracking consumer behavior based on actual data.

Back-End BPM

Robotic Process Automation: The automation of repetitive activities and high volume back-office processes with software robots to save labor costs, improve productivity, and boost accuracy.

Algorithmic Trading: AI for high-frequency trading, in which milliseconds are used to make investment decisions based on inputs from several financial marketplaces. It is reported that algorithms handle more than 70% of trade globally now

Investment Research: Artificial intelligence to help investors choose stocks. It can assist with research, portfolio management, and covering more firms in global exchanges.

Human Resources: AI to save hiring managers' time in a variety of recruitment processes, such as interacting with new hires, selecting resumes from social media platforms, pre-screening prospects via chat, estimating the likelihood that a candidate will drop out, etc.

REVIEW OF LITERATURE

Adrian Lee (Jan 23, 2017) Banking on artificial intelligence - This article's goal was to identify the most common applications of AI in the banking sector. The last one – AI-driven

customer care, real-time fraud protection, and risk management – might be the most alluring to people who are interested in disruptive industries.

Emmanuel Mogaji, Taiwo O. Soetan, Tai Anh Kieu 2020 - Artificial intelligence's effects on financial services' digital marketing to susceptible consumers. This study looks at how AI, digital marketing, and financial services relate to vulnerable consumers. It highlights important implications for information delivery, processing, and collection, and emphasizes the value of human interaction for the best possible customer experience and engagement with financial service providers. A successful implementation of AI requires an understanding of the data and modeling issues, as well as the ethical concerns. The theoretical framework this study offers to financial services providers, AI developers, marketers, politicians, and academics will help them better comprehend vulnerable clients' precarious situations and how to contact them.

OBJECTIVE OF THE STUDY:

1. To investigate how clients and consumers perceive artificial intelligence in banking and financial services.
2. To research the domains and applications in which the banking and financial services industry uses artificial intelligence.
3. To Study about Banking and Financial Services for using Artificial Intelligence is to offer customized product

SCOPE OF THE STUDY:

In certain private banks and other private institutions, research on artificial intelligence in banking and financial services is limited to the potential benefits to the client.

DATA AND METHODOLOGIES:

The information acquired contains qualitative primary and secondary data that was further examined to produce recommendations and findings. A survey on artificial intelligence in banking and financial services was used to collect the primary data. The survey's questionnaire was created, and random sampling was carried out. The internet was used to gather secondary data from sources such as newspapers, research papers, e-books, magazines, and the web.

INTREPRATION:

Above figure shows the consumer's perceptions about Artificial Intelligence in Banking and Financial Services which is determine most of the respondents strongly agree with Artificial Intelligence applications user friendly.

Useful Applications Of AI	YES	NO	TOTAL
	%	%	%
Chatbots	90	10	100
Voice Assistants	47.5	52.5	100
Authentication And Biometrics	65	35	100
Fraud Detection And Prevention	92.5	7.5	100
KYC/AML	97.5	2.5	100
Smart Wallet	67.5	32.5	100

INTERPRETATION:

The Above table shows that the frequency analysis for evaluating the useful applications of AI in Banking and Financial Services revealed that 90% of respondents says Chatbots applications of AI is very useful in BFS, 52.5% of respondents says Voice Assistants is not useful in BFS , 65% of respondents says Authentication and Biometrics is very useful, 92.5% respondents says fraud and detection and prevention is used to secure the data, 97.5% respondents says applications of KYC / AML is very useful to provide documents and other details to submit in BFS and 67.5% respondents says Smart Wallet applications in AI handling cashless Transactions in this generation.

CONCLUSION

Artificial intelligence provides various advantages for the banking sector. The findings suggest that Artificial Intelligence in Banking and Financial Services meets the needs of clients and consumers. Consumers in banking and financial services are well-informed about artificial Intelligence applications. Adoption of Banking and Financial Services AI applications were the most popular, followed by KYC/AML, chatbots, and security compliance. These technologies also aid in meeting client demands more quickly and easily. To increase consumer loyalty to banking and financial services, representatives should provide innovative training to enhance AI procedures in the workplace. It is also utilized for regulatory compliance, fraud detection, and creditworthiness assessments.

ABSTRACT

This paper determines a study of electrical motorcycle design. The aim of this study is to investigate how to design a simple, cost-effective model of electrical motorcycle with intelligent control system. This can be implemented by removing the internal combustion engine, the exhaust system and other unnecessary components from the motorcycle and replaced by an electrical motor, an intelligent controller, and a battery pack, cabling system and monitoring instruments

INTRODUCTION

In developing countries like India, there is a huge scope for electric vehicles that are ecofriendly and run purely with the help of electricity. As these e-bikes do not need any fuel to run them, the carbon and nitrogen emissions can be eliminated. The major reasons for selecting students and employees as the target audience are:

- Their awareness about the need for pollution control and about saving the most precious non-renewable resources.
- To serve their underlying and unidentified mobility needs.

The e-bikes can be charged using both AC and DC currents. Installation of DC current charging stations is slowly increasing across Hyderabad and across India as the government and private bodies are coming forward to increase the usage of green transportation. Also, these bikes can be charged normally with the help of regular household power sockets. The time taken for charging the battery and the maximum distance covered depend on the type of model selected. The increasing fuel rates will also be a major concern for the target market

when considering an electric bike over a regular conventional bike. The government of India is also promoting and encouraging the use of electric vehicles and trying to change future transportation in the coming years.

The electric bike is nothing but a bike that is driven with the help of a battery that is coupled to an electric motor. The Portable Electric Bike (PEB) was first developed in the 1890's in the US and documented in various US patents. On Dec 31st, 1895, Ogden Bolton designed a battery powered cycle. Six-pole brush and a Commuter DC hub motor connected to the rear wheel are used to design the cycle. He was also granted a US Patent. A Couple of years later, Hosea W. Libbey invented an electric bike driven by a double electric motor. This motor's design was such that it was attached to the crank set axle. Later in the 1990's, torque sensors and power controls were developed, carrying modifications in bike versions with NiMH, NiCd, and/or Li-ion batteries. But this bike faced a decrease in production when petrol and diesel resources came into existence. Initially, e-bike manufacturers failed because they were supplying motors with less than 250 watts, which were found to be weak and too slow for consumers. Also, these motors were brushed motors, which further reduced the efficiency of the motor by 20-25%. Now the trend is again going to change, and electric vehicles are in demand to solve major problems related to pollution, economy, and fuel availability.

The use of non-renewable and polluting sources to produce energy has taken environmental pollution to a whole new level. The increasing global warming has an impending need for us to stop the use of non-renewable resources and reduce carbon emissions. Since the industrial age, the atmospheric carbon content has been rising. Carbon emissions from vehicles amount for a typical passenger vehicle is 4.7 metric tons per year. The largest human source of carbon emissions is from the combustion of fossil fuels. The development of electrical engines in vehicles has created a replacement for internal combustion engines, paving the way for Electric Vehicles (EV's). EVs have been adopted by many countries since their development, creating a positive impact on the environment. We are now going to see the opportunities and challenges impending over implementing electric vehicles in India.

OBJECTIVE OF THE STUDY

- To determine the respondents level associated with different e-bikes,
- To find out the customer's various brands of e-bikes.

SCOPE OF THE STUDY

In this study, the usage and interest of the customer have been analysed. To find out factors that influence customers to buy e-bikes. To identify the necessary change in product future and customer feeling about the e-bikes. This study will be useful for the company to make necessary changes in price, model designs, etc.

Electric bikes need more advanced technology to improve performance and reduce cost. The Electric bike project will be successful with more research work in the following areas.

- Wireless power charging system for an electric battery

- Design of motors with high efficiency and high torque at low speed

- The Design of the battery has longer running hours and a lighter weight with respect to its high energy density and high output voltage.

- Design of an intelligent controller

- Cost reduction

METHODOLOGY

The Field survey method has been followed for studying the customer satisfaction of the e-bike users in the entire Salem.

SOURCES OF DATA

The survey method was deployed in this study to gain insight into and knowledge of the factors that influence the user's perception of purchasing e-bikestwo-wheelers in Salem town. The primary data for the study was collected through a structured questionnaire. The relevant secondary data was collected from journals, newspapers, published information, and details on websites taken for study. In my study, the method of collecting data is primary data.

SAMPLING

The present study has adopted the convenience sampling method, which comes from the non-sampling method. Among 38 districts in Tamil Nadu, the Salem district was purposefully selected by the researchers for the purpose of simple random sampling for the selected respondents to access.

FRAME WORK ANALYSIS

The collected data were subdued into a digestible account by appropriate coding, computing, and tabulation. The basic tools of statistical analysis, like simple percentages, were employed.

TOOLS USED FOR STUDY

For the collection the required primary and secondary data from the publication and individuals, a comprehensive questionnaire was prepared and used. The questionnaire covered all the areas related to customer satisfaction.

DATA ANALYSIS AND INTERPRETATION

Gender Classification of the Respondent

In this study, the gender of the respondents was classified into two categories, viz., the male category and the female category. The level of satisfaction of the respondents based on their gender is given below.

Particulars	Number of the Respondents	Percentage of the Respondents
Male	30	60
Female	20	40
Total	50	100

INTREPRETATION

The above table shows that the majority (60% of the respondents) were male and 40% were female.

SUGGESTIONS

There are numerous problems in this study. First, thanks to the restrictions on resources, we have only analyzed six main probable impacting factors based on RCT. There are many aspects that may affect Indian consumers' purchasing willingness, for example, fuel savings (Krupa et al., 2014), performance attributes (Wang and Liu, 2015), etc. Secondly, India is a growing country. It is inescapable that the divide between the rich and the impoverished in different cities is enormous, notably the gap between first-tier cities and other cities. However, in our sample, the proportion of first-tier cities amounted to 63.9 percent. This may have a tiny effect on the results. Thirdly, the link between purchase cost and government financial incentives is overlooked when examining the important factors of electric vehicle purchasing. Both the purchase cost and government financial incentives are not only monetary factors but also constraints. Obviously, the interactive linkages between them may be complicated, as the existence of financial incentives could minimize the cost of buying. In addition, the results reveal that the intention of Indian buyers to get electric

automobiles has no substantial relation to the acquisition cost. But the government's financial incentives have a beneficial impact on the Indian tendency to get electric autos. Thus, it is doubtful whether there are further linkages between them. since this study simply focuses on the India market, it would also be vital to undertake future research on a global scale.

CONCLUSION

The frequency distribution of respondents showed that most of the respondents in the survey are men. The awareness of electric bikes among the respondents is high; very few respondents were unaware of these bikes. Though awareness is high, most of the respondents said that they have never used electric bikes. Responses about perceived advantages and preferences for various attributes of e-bikes were collected through a 5-point Likert scale, and an in-depth analysis was performed using statistical techniques like correlation and regression.

Females are more interested in using electric bikes than males, so the company can introduce variants that attract males. The company should focus on developing advertising campaigns that communicate the need for and importance of using electric bikes. Increasing pollution rates and fluctuating fuel prices are the top concerns, which strengthens the need for the immediate adaptation of e-bikes. The latest plans and schemes by the government of India bring a lot of scope for e-bike subscriptions and sales in the coming few years.

ABSTRACT

The global business development in this Millennium is attributed to the rampant growth of Multinational companies. The purpose of this paper is to explore different insights in Globalization, Nationalism and Ethnocentrism and to understand the relationship among these phenomena in Business management. Exploratory research design was adopted in which after reviewing of literature selective perspectives pertinent to recent researches are segregated and administered into a brainstorming session. This area can be explored for formulating the research problem in the present-day context where the demarcation between globalization and localization is fading away. The output of the brainstorming is categorized into two – (i) Points laying stress on the review of literature (ii) Points which leads to new perspectives. The different perspectives which were used are (i) Monetary stabilization (ii) Cultural changes and diffusion of culture (iii) Companies becoming big (iv) Technology and Data transfer. The factors influencing and steps to be taken to renegotiate national identity can be studied. The outcome can be used for further research to substantiate with the hypothesis. The outcome gives a guideline to Marketers to build strategies for a global brand to be seen as regional brands.

INTRODUCTION

Globalization changed human lives everywhere. The integration of societies and national economies as well as disassociations have been a matter of interest and discussions in all sections of the population. Globalization refers to free cross-border movement of goods, service, information, and people. It is the phenomenon which creates networks of connections among actors at multi-continental distances, mediated through a variety of flows including people, information and ideas, capital, and goods. The entry of the Internet and modern technology has reduced the cost of transportation and communication. Globalization removed national boundaries and integrated national economies, cultures, technologies, and governance, resulting in a complex relation of mutual interdependence. “Globalization refers to the intensification of cross-national economic, political, cultural, social, and technological interactions that leads to the establishment of transnational structures and the integration of economic, political, and social processes on a global scale (Dreher, Axel, Noel Gaston, 2007).

Globalization can be seen as a socio-economic process which symbolizes the economic development of a country. In this sense, India witnessed Globalization during the first century when Alexander the Great made eastward link with Chandragupta Maurya connecting Mediterranean, Persia, India, and Central Asia. In the modern Globalization era, India witnessed an economic liberalization plan during 1990 after which economic growth galloped and now India is one of the fastest-growing economies with an average growth rate of 6-7 percent per annum and a significant rise in the per capita income and standard of living.

OBJECTIVES

Twenty-five years since India had achieved globalization in all dimensions, yet anti-globalization protests are seen in several parts of the country. Recent Youth Movement in Tamil Nadu to bring back “Jallikattu” – a traditional bullfight festival which was banned by the court, saw uproar against globalization policy of the government. The protestors voiced to ban Multinational companies. Even a few places witnessed consumers boycotting products of Multinational firms. These kinds of incidents motivated the researcher to understand why people are against Globalization. And why and how people connect issues

pertinent to Nationalism. Also, to understand why people connect ethnocentric views and patriotism with Globalization.

METHODOLOGY

Exploratory research design was adopted in which after reviewing of literature selective perspectives pertinent to recent researches are segregated and administered into a brainstorming session. The area can be explored for formulating the research problem in the present-day context where the demarcation between globalization and localization is fading away.

India has around 32 per cent of the population in the age category of 20 – 40 years (census 2011). This youth population is the major group in terms of voters' population and is going to be the future productive segment. Engineering students who read newspapers or watch television news daily were selected as the target audience. This group is considered as the reference group who has a good awareness of global happenings. The sheer importance of this group is very much evident through their active involvement in social media which is also kept one of the selection criteria. The researcher moderated the brainstorming session in this group along with the help of a scribe.

REVIEW OF LITERATURE

Economic Globalization

The evolution of the global economy by the way of increasing direct foreign investments and the conversion of international business to Global business better explain Globalization. The capital with its all forms is the main resources with its volume and speed is not only on the increase, but the easiness in fund transfer is also remarkable (Lupan, 2010). Though there are different definitions and different meanings interpreted globally, a unique interpretation was given by Charles wolf Jr., "Globalization is the increased speed, frequency and magnitude of access to national markets by non-national competitors." The parameters in measuring globalization are the market integration, reduction in prices, wages and real interest rates, percentages of GDP through exports (Wolf, Charles, 2000)

Competition at global level forces companies to produce on larger economies of scale and these larger companies make force local companies out (Angel, 2001). "It is true that

Globalization is accompanied by increased inequality in income (although the former doesn't necessarily cause the later)" (Wolf, Charles, 2000). Globalization brings interdependence, but the asymmetries of that dependence along with the hierarchical flow and the relative position will help to shape the nature of global power over the next decade (Angel, 2001). There are enough case studies and data to substantiate that the poor wage earners get benefit in exporting sector or in sectors where foreign investment comes and contrary poverty rate increases in the previously protected sector which were exposed to import. Again, the winners and losers are among the poor affected and supported in certain sectors (Harrison & McMillan, 2007)

Economic globalization is different from political integration, culture integration, various countries' sovereign interest's integration. In the line of Economic globalization, the national interests are fundamental to resist "the interference of new liberalism, neither take the old rigid closed, nor change the nature of society, we should adhere to the correct direction of the reform, improve the socialist system with Chinese characteristics" (Wang & Jia, 2015)

Cultural Globalization

Geert Hofstede defines culture as the collective mental programming which is being shared by members of a nation, region or group but not with members of other nations, regions or groups (1983). Culture can influence the acceptance of new ideas and products. Both male and female respondents in an empirical study in South Korea have favourable attitudes towards economic and cultural globalization – gender has no impact on attitudes (Suplico, 2008)

It is understood that consumer culture is exhibited at three levels – one at the Global consumer culture level, the second at National consumer level or Regional level and third is the Individual consumer level. Marketing strategies are formulated by understanding the three (Mooij, 2015). Marketers have to reach consumers one way or another, and this is generally done via mass media through which individual consumer cannot be identified. Although the internet allows reaching individual consumers by following their buying behaviour, the costs are high and it is not easy to link to personal values. Tracking individual customers' value orientations are costly and time-consuming and may not only be conducted for high net worth or frequent customers

Upon investigating with conjoint analysis, different types of products concerning global vs. local brand perception, the authors say that cultural characteristics are more important for high involvement products and vice-versa. Whereas some of the previous studies state otherwise also. Global consumers are more led by visual cues that symbolize global status and prestige and membership of a particular global group. Local advertising elements have often been related to self-congruity and self-relevant thinking which could be a more cognitive and central process. (De Meulenaer, Dens, & De Pelsmacker, 2015).

Technology Globalization

The internet is highly useful in accessing information from the past and becomes part of life, work and study. Internet brings transparencies and government; people use all kinds of patriotism education and publicity. Under the background of economic globalization, no matter where you are, no matter when you are contributing – this is facilitated by technology (Wang & Jia, 2015)

Nationalism

Nationalism is developing and maintaining a national identity based on shared characteristics such as culture, language, race, religion, political goals or a belief in common ancestry (Triandafyllidou, Anna. 1998). Nationalism like patriotism, which includes a sense of pride in the nation's achievements. But along with taking pride, it means others are inferior to you. Nationalism, unlike patriotism, is keen in exhibiting and celebrating with others.

Ethnocentrism

Ethnocentrism is judging another culture solely by the values and standards of one's own culture (John T. Omohundro, 2008). Consumers' openness to foreign culture, conservatism and fatalism determine the level of Ethnocentrism. Also, consumers show their ethnocentricity in selected local consumer products. Therefore foreign importers from countries of dissimilar culture may want to restrain using the products' country of origin. Ethnocentrism as part of consumers' "emotional factors" play a vital part in determining the consumers' preference for either local or imported products and so marketers need to understand consumers' motivation for buying domestic versus imported products (Kamaruddin, Mokhlis, & Othman, 2002). In an empirical study conducted in

China, it was found that the associations of nationalism had a strong link to foreign policy preferences than patriotism (Sinkkonen, 2013). 'In a globalized world, many features of nationalism seem to have a revival - Mixing cultures and newly emerging hybrid cultures make it hard for people to find their identity and let them turn towards their own culture" (Christian von Campe, 2008). Many Indians migrated to the United States and elsewhere twenty-five years before are coming back to lead a life with the property they earned yesteryears.

Patriotism

"Patriotism in the conditions of globalization is not focused on national isolation and self-sufficiency: it is aimed at the presentation of cultural achievements of the nation to the world with the use of modern communication technologies. Understood this way the patriotism could become a counterbalance of westernization and condition of successful development of a national community" The homeland is considered as brand made up of the economic, cultural and political image and patriotism in today's context is to promote this to the world(Kuzmin, Kuzmin, & Komelina, 2016)

Singapore government during the eighties introduced policies to break down the barriers separating ethnic communities and forge a Singapore identity. Government's use of integrated school, bilingual education, public housing, and the promotional of a national identity (a cultural institution) as bridging institutions to assist in the implementation of multiracial policies. The equal treatment of the four streams of education - Malay, Chinese, English, and Tamil - laid the foundation of Singapore's multiracial policy development and subsequent implementation of the bilingual education system. The integrated schools with common curriculum gave importance to the English language to prevent conflict based on ethnic difference. The government measures of promoting English, economic growth through international trade and multinational corporation, led Singapore to achieve political stability and economic growth, they have led to a weakening of social bonds which are critical for patriotism. Patriotism in political leaders and citizens gave ways to find measures to renegotiate national identity(Kluver & Weber, 2003).

RESULTS AND DISCUSSION

It was well established with a preliminary discussion that the group is well aware of the intricacies of Globalization, the deep-rooted establishment of the phenomenon and the benefits and misfortunes. The group came out with enough cases and reasons to justify that the societies from different part of the globe are connected through language, transportation, trade, families, tourism, and educational exchanges. The other dark sides of this are the illegal flow of money, money laundering, and drug as international commodities, arms trade, and prostitution. Though the perspective of Globalization is viewed in different dimensions, the study considering the target group has shortlisted few areas of study, such as (i) Monetary stabilization (ii) Cultural changes and diffusion of culture (iii) Companies becoming big (iv) Technology and Data transfer.

It is irrational when people protest against Pepsi for drawing water which other local company also does. But the underlying thought is Pepsi doesn't add any economic value to local society. The balance between what Multinational firm takes and returns is the question? The nationalistic measures taken by President Donald Trump in the US is seen as "against foreign nationals". Maybe, but the measures are not against cultural pluralism. Ultimately it is argued that whether every national including your people are being accommodated equally? Nationalism is something which becomes alive when the economic wellbeing gets affected.

Segregating the Financial globalization from the Economic globalization, the panel feels that globalization is much a political force when it comes to implementation. It may be told as a compulsion that we may be isolated from the mainframe economy. But it is not so, India has enough wealth to take care of its industries and population. Many economists also feel the same. Some way or the other it is the easy money which is coming in, keep an eye over the market.

The case of Singapore, one of the fastest grown globalized country says that it has lost its cultural identity. Different ethnic groups mixed up and have given a unique identity of its own. But there are people to regret that they have lost their original culture. Maybe an emotional value which guides every human being in his society is being present in a different form. This is where the anti-globalists are worried. The recent protest happened in the southern part of India, in Tamil Nadu, the youth population came to know about the

importance of their own culture, which happened when they are emotionally charged with different issues. This type of unrest then and there educates people on the disadvantages of globalization which creates fearsome that their native original culture may extinct.

Over a period, due to successful positioning and regionalization of multinational brands, many Indians are not able to differentiate native brands from Multinational brands. Most of the FMCG products of Unilever, P&G, and Reckitt Benckiser are seen as native brands. What criteria according to a common consumer is that which differentiate a native company from foreign company? Is it the country of origin or the shareholders' pattern etc. much nuances which cannot be understood to define the stamp as a foreign company? Also, globalization paves way too many industries where consumers do not have knowledge and awareness on business brand. These attributes to the characteristics of globalization to be emotional rather than rational. Patriotism in consumers makes them take pride when their native firm achieves at the global level.

Technology transfer across all industries is comfortable after the boom of Information Technology. Technology is seen as the binding force which binds all forms of globalization vis. Political, Economic, Financial and Cultural. Though all are interrelated, technology is one which is used in communicating the existence and at times used to manipulate. The nationalism and the globalization as thoughts both exist in the same person. The person who went out of the country praises globalization again wishes to settle in his native place at his home country in search of their identity. In this process Technology in its part connects everyone in the form of a global village. Earlier, going with the Product life cycle theory of international business, developing countries become the production ground for developed countries, where economy and employment development happens at the cost of environmental degradation. Recent years green technology adopted in developing economies envisages real development. If we analyze the effects of globalization with some specific measures, then the stories of failures outweigh the benefits. In India, if we consider the overall industrial development, the average annual growth rate of Indian Industry has declined from 7.8 percent to 6.7 percent, in the post-reform period as compared with the pre-reform period. And there was again a decline in the manufacturing sector comparing these two periods (Kumar, 2014). Though there is a conceptual clarity between Nationalism and Patriotism – well explained through different researches, our brainstorming session showed

many overlapping between two. Further discussion led to the conclusion that the transition towards globalization away from ethnocentrism will be smooth and less conflict when economic progression is fast. Singapore is the best example of this.

CONCLUSION

Various factors which differentiate a foreign company from domestic one varies in different geographies in different period. This area clarifies the common cultural aspects between the two nations. The impact of national identity in consumers while he chooses a product needs to be identified. The factors influencing and steps to be taken to renegotiate national identity can be studied. The nationalistic role played by those who have migrated to another country. The globalization of native culture and its impact on the consumers of native land. The globalization of Green technology and its impact on localizing products. The work of Green organization around the globe in bringing globally acceptable products and services. Prioritizing different forms of Globalization and its comparative impact on Nationalism. This trend prediction helps policymakers and marketers to undertake precautionary work to accommodate globalization and Nationalism. Most prominent antecedents of Nationalism and ethnocentrism needs to be deduced so that it's overlapping with globalization can be ascertained.

ABSTRACT

The widespread adoption of mobile devices among students has brought about significant changes in their daily lives, education, and social interactions. While mobile technology offers numerous benefits in terms of accessibility to information and communication, it also presents several adverse effects that can impact student's academic performance, mental well-being, and overall health. This review explores the negative consequences of excessive mobile usage among students, including distractions during study time, decreased academic productivity, disrupted sleep patterns due to screen time, physical health issues such as eye strain and musculoskeletal problems, and mental health challenges like anxiety, depression, and social isolation. Factors contributing to excessive mobile usage among students, such as addictive app designs, peer influence, and societal pressures, are also discussed. Strategies for mitigating the adverse effects of mobile usage, such as promoting digital well-being, setting usage limits, encouraging offline activities, fostering digital literacy, and providing mental health support, are highlighted. Understanding these adverse effects and implementing proactive measures can help students achieve a healthier balance between mobile technology use and their overall well-being.

INTRODUCTION

In our modern digital age, mobile devices have become ubiquitous, especially among students. From smartphones to tablets, these gadgets offer convenience and connectivity like never before. However, alongside their benefits, excessive mobile usage among students has

raised concerns due to its adverse effects on various aspects of their lives. This paper delves into the detrimental impacts of prolonged mobile usage on students' academic performance, mental health, social interactions, and physical well-being.

Extending the duration of mobile usage has been linked to decreased academic performance among students. Constant distractions from notifications, social media, and gaming apps can disrupt study habits, leading to decreased focus, productivity, and ultimately, lower grades. The temptation to multitask while studying often results in shallow learning and poor retention of information, affecting overall educational outcomes.

Needless mobile usage can take a toll on a student's mental health. The constant pressure to stay connected and engaged online can contribute to heightened stress, anxiety, and even depression. Social media platforms, in particular, can exacerbate feelings of inadequacy, FOMO (fear of missing out), and cyberbullying, negatively impacting students' self-esteem and psychological well-being.

Heavy reliance on mobile devices for entertainment and socializing can lead to reduced face-to-face interactions and weakened interpersonal skills among students. Real-life communication skills such as empathy, active listening, and non-verbal cues are crucial for personal and professional development but may be neglected in favor of digital interactions. This trend can hinder students' ability to form meaningful relationships and navigate social situations effectively.

Over the top of mobile usage can contribute to physical health issues such as eye strain, poor posture, and disrupted sleep patterns. Excessive screen time, especially before bedtime, can interfere with the production of melatonin, a hormone essential for regulating sleep cycles, leading to insomnia and daytime fatigue. Additionally, repetitive use of mobile devices can strain muscles and joints, contributing to conditions like text neck and carpal tunnel syndrome.

SIGNS OF SMARTPHONE ADDICTION FOR STUDENTS

- Teens spend hours on their cell phone
- Lack of interest in other activities
- Inability to access their devices results in agitation and anger

HARMFUL EFFECTS OF MOBILE PHONES ON STUDENTS

1. Poor vision: Constant staring at mobile phones affects eyesight and eye health. Eyes tend to get dry, and the vision blurry. The eyesight gets affected, too, and kids have difficulty reading. Using phones day and night ruins eye health and the repercussions last a lifetime. This is one of the worst negative effects of mobile phones.

2. Lack of focus: The virtual world they view on their mobile phones is highly distracting. Students find it fascinating and spend hours lost in it. It is not only misleading but confusing, too. It also distracts them from their studies and sports as kids wish to spend more time with their phones than their books. They tend to lose focus and their academic performance suffers badly.

3. Anxiety: The wide array of video games and other applications not only disturb them but also cause anxiety in students. Students suffer from debilitating headaches and migraines due to this constant phone usage, which further leads to anxiety and depression.

4. Isolation: Poor performance in exams leads to isolation. Students prefer staying away from friends and family and lose themselves in their mobile phones. This can seriously harm their mental health.

5. Poor academic performance: The addiction to their phones leads to poor academic performance. Students fail to pay attention while studying, their memory suffers, and their mind suffers from dullness and lethargy.

6. Accidents: The addiction to mobile phones is so strong that kids seldom do not let go of their phones, even while walking on the street or crossing the road. This increases the possibility of accidents, too.

7. Sleep loss: Spending too much time on their phones disturbs their sleep. The radiations being emitted by mobile phones tend to disturb the natural sleep pattern and cause sleeplessness and the blue light emitted by the phones keeps the brain awake and alert even at night.

8. Bad posture: Staring at the phone screens all day long, with their heads bent and their shoulders drooped leads to bad posture, neck ache, headache, backache, and tendonitis.

9. Immoral activities: There is a lot of inappropriate content on the internet. Students, who are too young to differentiate between fact and fiction, find this mesmerizing and risk

getting misled. The pull of the virtual world is so strong, it increases social disturbance and moral downfall.

10. Cyberbullying: Students lack the maturity and the presence of mind to deal with cybercrimes or cyberbullying. They fall prey to the negative elements present in the virtual world and suffer from anxiety and depression besides low self-esteem due to the psychological bullying they might suffer at the hands of the cyberbullies.

PARENTS ROLE TO PREVENT MOBILE ADDICTION IN STUDENTS

Keep your child engaged: Play spaces are shrinking or non-existent, as a result children have no choice but to stay indoors. Consequently, they become captivated by gadgets like smartphones. Playgrounds and parks can be good places to take your child to prevent this. By reducing time spent on a smartphone, he/she is able to spend more time playing and running. If that is not possible, you can enroll your children in a neighbourhood sports club.

Educate your teen: A mobile phone is one of the most important tools a teen-needs to communicate with you and experience the world for themselves, so you need to choose the device that will be the most effective for them.

However, education is needed. Explain to them the dangers of modern technology while showing them how to safely use their phones. Ensure that you set boundaries and treat your teen with love - so they know you're doing things for their benefit. Educating your teenager requires some monitoring on your part. In this way, you'll stay on top of your teen even when they're not with you. Smartphone addiction is easy to acquire. Provide tools to your teen and tell them they can ask questions whenever they like before you allow them to take charge.

Set boundaries for phone use: You should also have a clear understanding of what to do in certain areas around the house as well as providing a structure for the house. Teens shouldn't use their cell phones during family outings, social events, while eating, or while studying. It is important to respect relationships before all else.

Monitor use as a family: When they feel watched, teens are looking for workarounds. Families should make monitoring a priority so teens are accountable for their behaviour online. You can monitor your teens' phone usage with apps like Fenced.AI. A new setting called "screentime" is available on the iPhone. The system can be used to monitor app use

and set balanced usage limits (e.g. xx hours per day for social media) and shut down apps at specific times. Set realistic and healthy limits for your teens.

Besides this, parents can try the following,

Instead of communicating via phone calls, communicating via video calls or using the phone on loudspeaker will reduce the contact between the phone and the head. This will save the brain from radiation exposure.

Parents can set an example by switching off their phone at night, when busy working, or when the phone is not needed. This will help improve concentration, attention, and sleep.

Parents can choose the right monthly plan which allows a particular number of phone calls and texts only. This will reduce the kids' phone usage and save them from the bad effects of mobile phones.

SURVEY & STUDY

We conducted a survey on a sample size of 76 students regarding mobile phone usages and their perceptions to know how students are using their mobile phones.

- Too much of mobile phone use can strain relationships with family and friends, as it may lead to neglecting face-to-face interactions in favour of online communication.

SUGGESTIONS

- Encouraging students to limit their screen time on mobile phone by setting daily limits using built-in device features or third-party applications.
- Designating fixed areas, such as study rooms or bedrooms, as tech-free zones to promoting better focus and relaxation without accessing the digital distractions
- Stimulate students to take regular breaks from their usage of mobile phones to reduce eye strain, prevent posture-related issues, and foster physical activity.
- Provide workshops or seminars to educate students about the importance of healthy mobile phone usage, including proper ergonomics, eye care, and mental health considerations
- Assist face-to-face social interactions among students to diminish dependency on virtual communication and foster interpersonal and intrapersonal skills.

- parents to set clear bounds regarding mobile phone usage at home, especially during study time, meals, and before bedtime, family time.
- parents and teachers to monitor the content students access on their mobile phone usage to ensure they are exposed to age-appropriate and beneficial materials.
- School and college hearten students to engage in offline hobbies and creative activities such as sports, arts, or reading to balance their online and practice in offline experiences.
- Teenagers should model healthy mobile phone usage to serve as positive role models for students and reinforce responsible digital habits.
- Providing support and services such as directing or mental health resources for students experiencing detrimental effects from excessive mobile phone usage, such as addiction or anxiety.
- One of the most effective ways to reduce the side effects of mobile phones on students is to reduce their usage. Educating them about the harmful effects of radiation is much more effective than just forcing them to stop using phones.

CONCLUSION

Mobile phones and other technological gadgets are useful to us in many ways, and are an important means of communication, too. However, limiting their use is a necessity because of the damage they do to our health. Being among the top International schools in Bangalore, GIIS teaches students about these kinds of topics with their advantages & disadvantages so that way students learn by themselves about harm mobile phones can do. Educating kids about the effects of mobile phones on their health, instead of controlling them, will help them understand the need to reduce their usage. It's wise to change their phone habits in time before the phones cause irreparable harm to their health.

Definition

Marketing strategy is a process that can allow an organization to concentrate its limited resources on the greatest opportunities to increase sales and achieve a sustainable competitive advantage.

Developing a marketing strategy

Marketing Strategies serve as the fundamental under pinning of marketing plans designed to fill market needs and reach marketing objectives. Plans and objectives are generally tested for measurable results. Commonly, marketing strategies are developed as multi-year plans, with a tactical plan detailing specific actions to be accomplished in the current year. Time horizons covered by the marketing plan vary by company, by industry, and by nation, however, time horizons are becoming shorter as the speed of change in the environment increases. Marketing strategies are dynamic and interactive. They are partially planned and partially unplanned.

Marketing strategy involves careful scanning of the internal and external environments. Internal environmental factors include the marketing mix, plus performance analysis and strategic constraints. External environmental factors include customer analysis, competitor analysis, target market analysis, as well as evaluation of any elements of the technological, economic in strategy is often to keep marketing in line with a company's over arching mission statement. Besides SWOT analysis, portfolio analyses such as the GE/McKinsey matrix or COPE analysis can be performed to determine the strategic focus.

Once a thorough environmental scan is complete, a strategic plan can be constructed to identify business alternatives, establish challenging goals, determine the optimal marketing mix to attain these goals, and detail implementation. A final step in developing a marketing strategy is to create a plan to monitor progress and a setoff contingencies if problems arise in the implementation of the plan.

MARKETING STRATEGY OF ONEPLUS PRODUCTS

2.1 Product Features

To sell a consumer durable product a company has to provide unique features i.e. features which other companies are not able to provide. Samsung has been using the same strategy to boost their sales. Samsung provides its consumers with wide range of products with unique features.

For example, Samsung was the only company offering 1000 watts PMPO sound out put in the 21-inch flat TV segment. It also introduced a new 5.5kg, top loading fully automatic washing machine with features like 'saree course' keeping in mind that the majority of the Indian women wear sarees.

Invitation system

Early phones were only available through a system where by costumers had to sign up for an invite to purchase the phone at irregular intervals. The system was claimed to be necessary for the young company to manage huge demand. One plus ended the invite system with the launch of One plus 3 on 14 June 2016. Announced via an interactive VR launch event, the One plus 3 initially went on sale within the VR app itself. One plus touted the event as the world's first VR shopping experience. The phone was made available for sale later that day day in China, North America and the European Union on the One plus website, and in India on Amazon.

Smash the past

On 23 April 2014, One plus began its "Smash the Past" campaign. The promotion asked selected participants to destroy their phones on video in an effort to purchase One plus One for\$1. Due to confusion, several videos were published by unselected users misinterpretation the promotion and destroying their phones before the promotion start date. One plus later revised the rules of their promotion by allowing consumers to donate their old phones. There were140,000 entrants in the contest with 100winners.

Ladies First

On 13 August 2014, Oneplus hosted acontest to give invites, which were hard to come by at the time, to their female forum members. Users were asked to post a photo of themselves with the Oneplus logo,images would be shared in the forum and could be “liked” by other forum members.

RESEARCH METHODOLOGY

- Marketing Research
- Sources of Data

Sales promotion usually targets brands witchers because non-users of other brands do not always notice a promoting.

3.2 Sources of Data

In this study the most data collection instrument use the questionnaire method.

$$\text{Percentage} = \frac{\text{Number of respondents}}{\text{Total number of respondents}} \times 100$$

The questionnaire has been designed with both open ended and close ended questions. Apart from this, the research instrument consists of primary and secondary data collected for the study.

Primary Data

Here first information is obtained by distributing printed questioners to the marketing executives of the company. Data was also obtained from the observation and interviews techniques adopted by the researchers. Moreover, information was disseminated by the departmental heads.

Secondary Data

Here the information is obtained from the brochure of oneplus group, books, websites, newsletter, generals, magazines, newspaper, etc.

DATA COLLECTION TOOL

4.1 Questionnaire:

A Questionnaire is a research instrument consisting of a series of questions and prompts for the purpose of gathering information from respondents. Although they are often designed for statistical analysis for the responses, this is not always the case.

4.2 Sample:

The selected respondents constitute what is technically called a “sample”. The group consisting of these is known as “sample”.

4.3 Sampling Techniques:

The sampling method adopted for this study was simpler and omsamplings. Simpler and omsampling (sometimes known as grab or opportunity samplings) is the method of choosing items in an structured manner from the population frame. Though almost impossible to treat meticulously, it is theme tho most commonly employed in many practical situations.

4.4 Sampling Design:

Sampling design is to clearly define set of objective, technically called the universe to be studied. Sampling technique used is simple random sampling method.

4.5 Sample Size:

Sample size is 53. It was collected by using questionnaire.

4.6 Tools For Analysis:

To arrange and interpret the collected data the following statistical tool were used.

- Percentage analysis.

PERCENTAGE ANALYSIS

Percentage refers to special kind of ration. It is used in making comparison between two or more series of data. It is used to describe relationship. It is used to analyses the data. Barcharts piecharts were used to explain abulation clearly

Chart No:2

FINDINGS

- A majority of the consumers are not use Oneplus products.
- Advertisement has been an effective method for spreading awareness about One plus products.
- A majority of the consumers have seen Oneplus ads.
- The logo/slogan and concept/message has been an important factor influencing the consumers.
- Many consumers find the marketing of Oneplus satisfactory and impressive.
- The logo/slogan and themes make people recall the brand.
- The advertisement reflects actual product profile.
- Majority consumers find Oneplus' products to be economical.
- Consumers have been satisfied with the after sales service of Oneplus.
- It's the product feature that induces the consumers to buy the product.

SUGGESTIONS

- Company should concentrate on improving the after sales service of products as it's an important factor for the sales of consumer products.
- Company should constantly get innovative in advertising its products, mainly focusing on Value it will bring to the customer after buying the product
- Company can use some of the marketing tactics like distributing free keychain, calendar, t-shirts for making brand popular among people
- Advertisements of the company's products should focus on quality and main features.
- Proper Segmentation should be done and accordingly marketing strategies should be planned for premium products.
- Welcome call as well as follow up call will help the company to maintain customer relationship; hence the company should focus on such after these aspects.
- Establish the service center as per the case of consumer accessibility.
- Company should undertake repeated advertising as it is an effective way to reach the consumers.

- Company should/may undertake more innovative advertising.

Although, marketing strategies currently undertaken, have been effective, not a little more can be done towards the same

CONCLUSION

With respect to the above study and the findings thereby are that the company has definitely entrenched into the urban market. With few more concerted efforts, the said organization needs to enter the rural market in order to completely establish itself all over. Customer Service and Satisfaction are of utmost importance in this highly competitive market. Value Proposition should be created in the eyes of the customer to gain Loyalty which will in turn help to sustain and be a Leader in the Market. Constant Investment in R&D will help an Organization to get Innovative products in the market and in turn lead to higher Customer Satisfaction. Brand Recall is of most importance and the Company should make efforts to increase the same. Exclusives how rooms are of utmost importance and other required investment should be done to expand for the same. Merchandises play an important role in extensive advertising and so the same should be innovated every now and then to take advantage of mass appeal. Picturization techniques can be improved by appointing more professional and so the investment for the same is proposed. Overall it's the product feature that attracts different segments of the population.

ABSTRACT

Recruitment is the most important function of the Human Resource Department in an organization in which there is a huge contribution of manpower. It is the process of identifying prospective employees, stimulating and encouraging them to apply for a particular job or jobs in an organization. It is a positive action as it involves inviting the people to apply. The purpose is to have inventory of eligible persons from amongst whom proper selection of the most suitable person can be made. Selection is the process of examining the applicants with regard to their suitability for the given job or jobs, and choosing the best from the suitable candidates and rejecting the others. Nowadays, AI (Artificial Intelligence) has made its entry in all professions. In the same way, HR professionals started using AI tools for recruitment to simplify the process and also to save time.

INTRODUCTION

Artificial intelligence (AI) is a set of technologies that enable computers to perform a variety of advanced functions, including the ability to see, understand and translate spoken and written language, analyze data, make recommendations, and more. It is a field of science with building computers and machines that can reason, learn, and act in such a way that would normally require the contribution of human intelligence or that involves data whose scale exceeds the limit or level what humans can analyze.

AI is a broad field that encompasses many different disciplines, including computer science, data analytics and statistics, hardware and software engineering, linguistics,

neuroscience, marketing, managing finance, production and operation of an organisation, recruiting and even philosophy and psychology. Out of these numerous disciplines to which AI is making its significant contribution, this paper is about to make a study on its role in recruitment process in an organization.

RECRUITMENT PROCESS:

Recruitment is the first step in building an organization's human capital. It is performed by Human Resource Department in an Organisation, whose function is to manage of people within an organization. HR is responsible for facilitating the overall goals of the organization through effective administration of human capital – focusing on employees as the company's most important asset. At a high level, the goals are to locate and hire the best candidates, on time, and on budget.

The recruitment process in human resources (HR) can be defined as the process of identifying, attracting, interviewing, selecting, hiring, and onboarding employees.

STEPS INVOLVED IN THE RECRUITMENT PROCESS:

- Identify the need for hiring
- Sketching a recruitment plan
- Write the description of job
- Advertise for the job position
- Recruit the candidate for the job
- Review the applications of the job
- Phone Interview or Initial Screening interview
- Conduct Interviews
- Assessment of the applicant
- Check the background of the applicant
- Decision to either select or reject the candidate
- Check the reference of the applicant
- Job offer to the applicant
- Hiring of the candidate
- Onboarding of the selected candidate

The above are the ways through which the traditional recruitment process takes place in an Human Resource Department of an organization which involves the working of manpower. These traditional hiring processes confront skill shortage, time-consuming manual processes and unconscious biases.

AI IN RECRUITMENT:

Artificial intelligence (AI) is revolutionizing the world of recruitment. So, it is no surprise that 43% of Human Resources professionals are already using AI in their hiring processes. AI for recruitment refers to the application of artificial intelligence technology in the hiring process to streamline and automate various aspects of recruitment. It allows recruiters to use the power of data to make better decisions. AI for recruitment can assist in sourcing and screening candidates, analyzing resumes and job applications, conducting pre-employment assessments, and even predicting candidate success and cultural fit.

By leveraging AI, recruiters can save time and effort, improve the quality of candidate matches, reduce bias, and make data-driven decisions. AI for recruitment holds the potential to revolutionize the hiring landscape by increasing efficiency, accuracy, and overall effectiveness in identifying and attracting the right talent for organizations.

Maximize Recruitment Efficiency:

Recruitment is typically a lengthy process that often involves a lot of manual work. The average recruiter spends up to 30 hours a week for this process. This can result in a significant loss of productivity. AI-based solutions can source through thousands of applications in an instant and identify qualified candidates. This can help HR teams significantly reduce the amount of time they spend on administrative work so they can focus on strategic tasks that will actually help you deliver results for your organization.

Overcome Recruitment Bias:

Almost 50% of HR Managers admit to being affected by unconscious bias when selecting candidates. This can result not only in bad hires but can also be limiting for organizations that are trying to build a diverse workforce. When utilized correctly, AI can counteract these biases and eliminate subjectivity in the hiring process. AI is able to screen candidates

objectively based on factors such as qualifications and experience without relying on subjective factors such as age, gender, and race.

Enhances candidate experience:

A survey revealed that nearly 60% of candidates declined a job offer due to poor recruitment experience. Not only can this discourage potential candidates from applying in the future, but it can also hurt your employer's brand. AI-enabled recruitment tools can help mitigate this problem by streamlining the entire application process and making it more efficient and enjoyable for candidates. By leveraging AI to make the recruitment process more engaging and personalized, you can significantly improve candidate experience and attract more qualified candidates.

AI SIMPLIFIED THE PROCESS OF RECRUITMENT:

AI is changing the way the hiring process works. It has already proven to be a smart and cost-effective means of speeding up the recruitment process while also improving the quality of hires.

Candidate sourcing:

AI-based sourcing solutions make it easier for recruiters to locate and connect with relevant talents more quickly. These tools use algorithms and machine learning to automate various tasks, including searching job boards, internal databases, and social media platforms, to identify and source the most relevant candidates for a particular role. Some of the AI-powered sourcing tools also provide recruiters with data-driven insights and recommendations, helping them make informed decisions.

There are a number of AI-based sourcing tools available in the market, each with its own unique features and capabilities. For example, some tools may focus on maximizing marketing efforts and connecting with candidates in real time, while others may have an AI chatbot that interacts with candidates to determine the best role fit and show them how to apply. These tools offer a wide range of benefits to recruiters, including faster candidate sourcing, improved accuracy and efficiency, and better collaboration with their team.

Candidate Screening:

Screening is a critical step in the hiring process as it helps to identify the most qualified candidates from a pool of applicants. However, this step can also be very time-consuming and manual, especially when dealing with large volumes of applications. This is where AI screening tools come into play. By utilizing AI technology, these tools can quickly extract important information from job applications that can be useful for hiring decisions and efficiently bring the best candidates to the forefront.

The methods used by AI screening systems vary, ranging from resume parsing to behavioral and skill evaluations. For instance, the AI screening system may identify red flags indicating incompatible personalities or behavior patterns that may not be a good fit for a particular role. These insights can then be used by the recruiter in the selection process to narrow down the candidate pool and focus on those with higher potential.

Talent Assessment:

AI-powered talent assessment tools are increasingly being used by companies to measure candidate competency and personality traits. These AI-powered tools offer a more comprehensive and efficient way to assess candidates by incorporating gamification, behavioral assessments, and skill testing. The data generated from these tools are analyzed by AI algorithms to provide an in-depth report on a candidate's strengths, weaknesses, and personality traits. This not only saves time and resources for the organizations but also provides a better experience for the candidates by allowing them to showcase their abilities in an engaging and interactive way.

The AI-powered assessment tools that are already widely used by organizations offer a range of features, including online gamified assessments, personality and skill assessments, culture fit evaluations, and social skills assessments. Moreover, most of these tools can be customized according to the needs of a particular organization and can be integrated with existing systems to ensure a seamless workflow.

Candidate interviews:

Candidate interviews are a crucial aspect of the hiring process, as they provide a direct assessment of the candidate's abilities and personality. While the traditional interview processes can be time and effort intensive on the part of the recruiter, AI-enabled interview platforms can significantly reduce human effort by streamlining the process and leveraging the power of data and analytics. For instance, these platforms enable recruiters to conduct pre-screening interviews with candidates through video calls and text-based interactions. These conversations are recorded and analyzed using machine learning algorithms to identify the best candidates for the next round of interviews.

AI-powered interview tools use voice and facial expression analysis to determine a candidate's tone, demeanor, and emotional state. These insights are then combined with the content of the candidate's answer to provide a more comprehensive understanding of their personality and fit for the role. In addition, these platforms can provide recruiters with valuable insights into the candidate's performance, such as the time taken to answer each question and their level of engagement throughout the interview.

Offer and Onboarding

When it comes to offering and onboarding, creating a positive and engaging experience for new hires is crucial in order to make a lasting impression. With AI-based tools it has become easier for HR teams to create an engaging and personalized onboarding experience for their new employees. From introducing new hires to the organization and its culture to helping them navigate their first days on the job, these solutions streamline the onboarding process and ensure a smooth and memorable experience for every new hire.

The use of machine learning and AI technology enables these platforms to understand the unique needs of each organization and provide a tailored onboarding experience while also scaling the process to accommodate large numbers of new hires. Ultimately, by prioritizing employee engagement and creating a positive first impression, organizations can set the stage for a successful and productive long-term relationship with their new hires.

PROS AND CONS OF AI IN RECRUITMENT PROCESS:

1) AI RECRUITING TOOLS IN TIME SAVING:

PRO: Time-saving tool for recruiting at scale

By instantly analyzing thousands of applications based on the data, AI recruiting solutions can often reduce the effort of identifying top talent by filtering out the better candidates in the fraction of a time it would take a person to do so manually. Depending on which AI is used, it can go beyond filtering to help schedule meetings and even conduct first-round interviews with the power of automated Q&A.

CON: Waste of time for less-frequent users

Learning to use these tools can be quite time-consuming, so if you're not recruiting often, it might not be worth the effort of the learning curve. And if you don't use it often, you will have to refamiliarize yourself with it—and its new features—every time you log on. These can both take longer than simply filtering the candidates manually.

2) AI RECRUITING TOOLS TO SPOT THE TOP TALENT:

PRO: Wide-ranging assessment

AI enables recruiters to cast the net much wider for talent by scraping information on potential applicants from across different networking sites, such as LinkedIn and other social media platforms, as well as additional existing online databases.

CON: Risk of missing out on top talent

With any AI tool, there's a real risk that of missing that ideal candidate the recruiter would have identified but AI cannot. When you use the tools often enough, you learn how to get around this issue, but occasional users lack the experience to do this. And as AI in recruitment becomes more widely implemented, it's inevitable some applicants will try to game the system, and many will also be using AI as well. This can mean that better-quality applicants fall through the net while less qualified applicants rise to the top.

3) AI TOOLS IN PROVIDING ACCURATE INFORMATION:

PRO: AI tools as information providers and gatherers

Many AI recruiting solutions incorporate generative AI engines, such as ChatGPT, which can have conversations with potential hires according to the prompts you add to the interview model. Built into your talent-acquisition software, automated chat assistants can provide job-seekers with vital first-stage information. They can share more detailed job descriptions and engage the candidate with typical interview questions with the power to respond to inquiries. Their questions and responses can provide recruiters and HR departments with a foundation for each candidate.

CON: These tools need human guidance to ensure accuracy

A justifiable and common criticism of AI such as ChatGPT is its accuracy. This should improve as it learns over time, but such improvements are partially reliant on human intervention and effective prompts.

4) AI TOOLS IN IMPROVING UNBIASED AND DIVERSE HIRING:

PRO: AI tools can help improve diverse hiring

Bias, whether conscious or unconscious, keeps many organizations from recruiting the best people. Integrating AI into recruitment can help overcome human bias by programming tools to identify only qualifications, skills and experiences relevant to the job description while removing indicators of race, gender and class. But bear in mind that it takes well-informed and thoughtful energy to truly ensure that proper diversity access for candidates is a primary component of your recruiting program, so factor this into your planning from the start.

CON: AI tools can also introduce bias

AI algorithms, whether bespoke or off-the-shelf, are programmed by individuals whose biases, if unchecked, will be incorporated into the end tool. Moreover, these AI algorithms are learning from historic data that likely incorporate biases inherent in past hiring decisions. Such biases can then be reproduced, and if left unchecked, could be disastrous over time.

You need to fully understand the capabilities and limitations of your tools to minimize the risk of this.

5) USE OF VIDEO CONTENT BY AI RECRUITING TOOLS:

PRO: AI video tools can improve interview flexibility and provide valuable data

AI vision tools supplement talent searches by sifting through social media accounts and video content for characteristics that might benefit an employer. Moreover, video-interview platforms allow candidates to interview on their own time, after which the visual and audio intelligence can be analyzed.

CON: Imaging platforms aren't for everyone

Left unchecked, these tools can discount qualified candidates for subtle, subjective differences, such as unusual speech patterns or self-consciousness, which could cause you to miss out on candidates who would be outstanding in the role, but don't do well on camera for any number of reasons, including neurodiversity. Human intervention is absolutely necessary to ensure bias isn't introduced into the analysis.

SURVEY AND INTREPRETATION:

According to survey conducted by TIDIO statistics & Tech Data Library on the impact of AI in Human Resource Management, it came out with the following statistical data.

INTREPRETATION:

Nearly 67% of HR professionals believe that AI has many benefits and a positive impact on the recruitment process. People think AI will free up the recruiter's time (44%), provide valuable insights during the recruitment process (41%), and make the recruiter's job easier (39%). But there are also those who believe that the use of artificial intelligence in hiring processes could lead to overlooking unique and unconventional talents (35%) and destroy the HR industry (26%).

FINDINGS:

- Above 95% of HR professionals think that AI could help with the application process for candidates.
- Over 29% of HR professionals from Gen Z think AI will replace them in the hiring process. But, only under 19% of Gen X and older are scared for their job.
- Around 79% of recruiters believe that people won't have to be involved in the recruitment process in the near future. But, most candidates (56%) think the final hiring decision should always be done by humans.
- Above 68% of recruiters agree that introducing AI to the recruitment process will remove the unintentional bias.
- Three main dangers of AI in recruitment are Overlooking atypical qualities and expressions, Algorithmic bias and Candidates manipulating the technology in order to get the job.

CONCLUSION:

It's clear that AI recruitment tools have the potential to save valuable time and money while being able to cast the net infinitely wider for candidates. But not all AI recruitment tools are created equal, and they require careful handling by people who are fully trained in the tools. What's more, some have been trained on better quality underlying data, so you need to investigate that before making a decision.

Before adopting AI recruiting solutions, every organization should have a team in place to ensure algorithms are fair by law, including conducting a regular "bias audit" and making hiring methods transparent. The legal issue is a huge one and not limited to biases. Mining

a wealth of data means security has to be top notch to prevent data leaks to the greatest extent possible.

At the end of the day, every AI recruitment solution pro comes with a caveat that human intervention can minimize. And experience as well as the underlying data and security are vital considerations.

ABSTRACT

The study is about the various spans of banking sector on which AI is impacting. AI can detect unusual patterns and correlate data in human- machine like manner and the earlier technologies were not able to do this before. As never before AI can identify hidden sales opportunities, cross selling opportunities, new untrodden avenues which are sure to have impact on the revenue of the organization, have edge over competitors and satisfy customers who are tech savvy.

Keyword

Artificial Intelligence, Banking sector

INTRODUCTION

Banking sector felt the need for computerization in 1980s. RBI in 1988 set up a committee headed by D. C. Rengarajan to discuss computerization of banks. Banks embraced the standalone PCs initially and then moved to LAN connectivity and further to Core Banking solutions. Liberalization further propelled banks to adopt technologies to stay competitive. Now Gen Z is the core driving force transforming the entire banking operations by their adeptness to technology. The banks revisit and update their service offering platforms. Global IT spending is to touch \$761 billion by 2025 and this is going to rewrite the manner the banks are going to function.

LITERATURE REVIEW

Geetha's (1) research reveals that above 90% of the customers appreciate Chat bot application in Banking and Financial Services and fraud detection and prevention by AI. Dr. Gurumoothy (2) opines that AI significantly contributes to the increase of the operating

profits of the banks. Suma. S.R., Anupama. S. (3) study findings reveal that majority of the customers have found AI has enhanced the speed of administration and improves security. Dr. V. Padmanabhan, V. Princy Metilday (4) express their fear of AI superseding human.

Optimisation of operations

AI embraces various tech like machine learning, natural language processing, and computer vision which work together to analyse voluminous data efficiently and securely, make decisions and automate powered. AI optimizes banking operations enabling data retrieval and the precision of the same are very high. AI also automates the tedious manual tasks like data entry, document verification, transaction processing and replies to customer queries reducing the time and human errors. While block chain ensures secure and tamper proof transactions AI enhances intelligence further.

Improved customer experience

Customer experience is crucial for business success in digital age. Any customer would leave a brand if they get two to three bad experience with the brand. Customers are more likely to buy brands that recognize, recall and provide relevant offers and recommendations. The competitive edge of an organization would lie in offering rich customer experience. AI imitates human brain and act intelligently as human brain does. McKinsey reports that AI has high growth potential in banking sector and it will reach \$ trillion soon and 80% of the banks have accepted that AI is sure to add advantage.

Fraud detection

Fraud log reports, deceptive e-mails and patterns of security can be tracked by AI. It also can track time, frequency and location to pin point suspicious activity. AI understands the fraud patterns and identifies suspicious activities very quickly. For example if multiple quick transactions happens it may be an attempt to use the credit card that has been stolen. Sudden spending surges and purchase of unusual categories of products in unusual locations can be easily detected.

Assured security

AI strengthens the security processes by encrypting each step with codes that authenticate transactions, provide information on fraudulent activities and money laundering activities. The KYCs help to strengthen the security measures. AI empowered contract analysis using advanced natural language processing algorithms can analyse complex legal documents. By this bank can rationalize operations, alleviate risks and make more prudent decisions.

Market predictions

AI helps in analyzing massive market data and make predictions and this allows banks to understand the market fluctuations and capitalize on the same. It can know market trends from various sources such as social media, magazines, and news reports. This helps to minimize potential risks and make strategic investments. This enhances returns and helps to stay competitive. In times of high volatility such as natural disasters, political unrest and currency fluctuations AI helps in making wise business decisions

Credit worthiness assessment

Banks need to assess the credit worthiness of a customer when it receives loan application. AI analyses customers 'transactions, credit history, defaults, spending history, savings pattern etc and understands complete financial behavior of a customer which helps to assess the credit worthiness. AI analyses diverse data sources faster and with accuracy and precision making loan appraisals with minimal errors. AI helps the customers to manage their wealth by giving advices and risks and investments. By extensive analysis AI tracks the market trends and informs the customers on the risks in the market.

Improved customer relationship

In banking industry customer relationship is pertinent and AI supported chat pots ensures 24/7 customer support. These chap bots are patient and answer queries of the customers in multiple languages. These chat pots help with pass word reset, knowing one's account balance, interest rate and do other transactions as well ensuring relationship management. Chat bots assist users in checking their credit ratings and provide advice to improve the same. Banking is the industry in which trust, empathy and understanding are

vital. AI helps to understand the personalized goals of the customers and offer personalized advice. In barely two months' time of its launch GPT- 3 supported Chat GPT has reached 100 million active users and is the fastest growing application. Chat GPT is a language model that uses machine learning technique of AI and natural language processing for generating human like responses to queries.

Enhanced customer services

AI analyses customer data, to know their preferences, interests and needs and use the information to offer customized products and services. The customer choice, data gathered from the customers help machine decode next decision using AI. Interactive Voice System is such AI powered systems that provide voice support to the customers by routing their calls to the correct desks and assisting them with the other bank related issues. AI guides customer by verifying their identification, help them on board, start accounts and provide guide on available products. A step further product recommendation also can be done. AI helps to increase customer participation, offer personalized services, improved service response and reduces human error thus increasing customer trust and satisfaction. AI identifies the emotions of the customers based on the text they use and respond suitably with the same tone of word with the help of natural language processing.

Customer behaviours such as consistent bill payments, saving habits, money withdrawal patterns, on line shopping etc helps to predict customer needs and give rich experience. AI collects massive data on demographics, account balances, online interactions from various sources.

Conclusion

Despite the advantages there are also concerns in implementation as the maintenance cost is very high. The industry need to balance between effectiveness and cost. The regulatory compliance, security threats and integration hurdles also have to be handle with deftness. There is also a fear that the machines will supersede human and the fear of losing jobs looms. However the power of AI cannot be underestimated and it is sure to sweep all the industries as done by computers in 1980s.

ABSTRACT

Representative wellbeing is a basic part of keeping a solid and useful workplace. This theoretical investigates the significance and advantages of carrying out representative wellbeing estimates in associations. It features how these actions add to diminishing mishaps, expanding efficiency, upgrading organization notoriety, accomplishing cost reserve funds, guaranteeing administrative consistence, and further developing worker fulfilment and maintenance. By focusing on worker wellbeing, associations show their obligation to the prosperity of their labour force and make a positive and secure work environment.

INTRODUCTION

Employee Welfare includes anything that is done for the comfort and improvement of employees and is provided over and above the wages. Welfare helps in keeping the morale and motivation of the employees high so as to retain the employees for longer duration. The welfare measures need not be in monetary terms only but in any kind/forms. Employee welfare includes monitoring of working conditions, creation of industrial harmony through infrastructure for health.

Labor welfare entails all those activities of employer which are directed towards providing the employees with certain facilities and services in addition to wages or salaries

Wellness includes activities carried out for the betterment and comfort of employees and provided in addition to wages. Happiness is a broad concept that refers to an individual's

state of life in which accretion is the desired relationship with the global environment - ecological, economic and social.

Employee welfare includes both the social and economic content of well-being. According to Todd." "Employee welfare means anything done for the comfort and betterment, intellectual or social, of an employee other than wages paid which is not an essential need of the industry".

Benefits include all that is done for the comfort and betterment of the employee and provided in addition to wages. Wellbeing helps to keep employees' morale and motivation high to retain them longer.

Welfare measures need not only be in money, but in all forms. Employee benefits include controlling working conditions, creating social harmony through health infrastructure, industrial relations, and workers' sickness, accident and unemployment insurance.

FEATURES OF LABOUR WELFARE

- Labor welfare includes various facilities, services and amenities provided to workers for improving their health, efficiency, economic betterment and social status.
- Welfare measures are in addition to regular wages and other economic benefits available to workers due to legal provisions and collective bargaining
- Labor welfare schemes are flexible and ever-changing. New welfare measures are added to the existing ones from time to time.
- Welfare measures may be introduced by the employers, government, employees or by any social or charitable agency.
- The purpose of labor welfare is to bring about the development of the whole personality of the workers to make a better workforce.
- The very logic behind providing welfare schemes is to create efficient, healthy, loyal and satisfied labor force for the organization.

OBJECTIVES OF THE STUDY

- To learn about employee welfare measures at HYUNDAI MOTORS LTD
- To measure the effectiveness of employee welfare measures at Hyundai.
- Analysis of employee satisfaction with social activities at Hyundai.

- Proposing new health care measures.

SCOPE OF THE STUDY

This study aims to determine employee satisfaction, if the company provides the necessary measures of health, safety and well-being. organ. This study focuses on motivational practices in companies at different employee levels.

RESEARCH METHODOLOGY

The basic principle in the research has been adopted in the overall methodology. The following methodology has been used for meeting the requirements,

- Defining objectives
- Developing the information sources
- Collection of information.
- Analysis of information
- Suggestion

The methodology followed for collection, analysis under interpretation of data in are explained below.

RESEARCH DESIGNS

There are generally three categories of research based on the type of information. required, they are

- Exploratory research
- Descriptive research
- Casual research

The research category used in this project in descriptive research, which is focused on the accurate description of the variable in the problem model. Consumer profile studies, market potential studies, product usage studies. Attitude surveys, sales analysis, media research and prove surveys are the,

Examples of this research. Any source of information can be used in this study although most studies of this nature rely heavily on secondary data sources and survey research.

Primary Source

Discussions with plant staff, Interviews, Questionnaire administered.

Secondary Source

Journals Magazines and articles from prominent newspapers.

SAMPLE DESIGN

Sampling unit; the study is directed towards the executive of managerial level.

Sample size: sample size of 60 is taken in this study

DATA ANALYSIS

Simple analysis method is followed for analyzing the data pertaining to different dimensions of employees. Simple statistical data like percentage are used in the interpretation of data pertaining to the study. The results are illustrated by means of bar charts

INTERPRETATION

The above table shows that Education Qualification of the respondents,38% of the respondents are diploma in education, 31% of the respondents are graduate in education ,17% of the respondents are post graduate in education, and 14% of the respondents are school level in education. Majority 38% of the respondents are diploma in education.

CHART NO - 4.4

EDUCATION QUALIFICATION OF THE RESPONDENTS

FINDINGS, SUGGESTIONS AND CONCLUSION

FINDINGS

1. Thus the majority 41% of the respondents are under the age group of 40 to 50.
2. Thus the majority 60% of the respondents are female in gender.
3. Majority 43% of the respondents are experience below 1 year in experience.
4. Majority 35% of the respondents are Strongly agree with safety benefits provided by the firm.
5. Majority 60% Of the respondents are yes in employee welfare measures is needed.
6. Majority 36% of the respondents are want life insurance in welfare measures benefits.
7. Majority 31% of the respondents agree in healthy facilities.
8. Majority 35% of the respondents are high satisfied in the healthy environment.
9. Majority 50% of the respondents are yes in the employee measures.
10. Majority 40% of the respondents are Normal is working condition.
11. Majority 35% of the respondents are feel good with first aid in safety measures.
12. Majority 35% of the respondent are happy in work environment.
13. Majority 41% of the respondents say friendly relationship with good management and co-ordination.
14. Majority 41% of the respondents say bonus in the service provided by the organization.

15. Majority 50% of the respondents say no stress in the organization while doing work.

SUGGESTIONS

The following are the suggestions to the company to improve the safety measures of the employees. The research suggests to the industry to check the machinery condition and make service at a periodical time and to control the environment by planting trees around the industry and nearby villages or areas. The study also suggests to the industry to concentrate in the working conditions like lightning, safety equipment, which is not to the satisfaction of the employees.

CONCLUSION

The study aimed at finding out the safety measures of workers in Hyundai Private Limited at Namakkal. For this purpose, a sample size of 60 was taken and satisfied random sampling techniques was adopted to choose the respondents. Management requires to offer exact centers to all employees in order that personnel are glad with worker welfare centers. It will increase productiveness as well as pleasant and amount. Therefore, it is vital to arrange to enhance the facilities via the happiness of the employees, the increase in the overall performance of the employees. As a result, efficiency, effectiveness and productiveness can be progressed to obtain organizational desires.

ABSTRACT

The paper is an attempt to find out factors influencing online buyers, as well as those factors. This study is to recognize the effectiveness of social media, effectiveness of buying behavior and problems of social media on buying behavior. The study is based on the survey of Paavai Students in Namakkal district. The study reveals the vital role of the social media in making the positive impact on buying behavior among the students. It is an outcome of the study that, the social media like Facebook, Instagram and Twitter are highly effective on the students buying behavior. Also, a model changing students buying behavior towards selecting certain product, age group by using the most suitable social media and buying behavior equation will be the best tool for products reach and advertisement. Output of this study will help online marketers, bloggers, vendors, executives and marketing managers to adopt social media effectively and efficiently to promote and maintain the existing customers, attract more users in order to achieve their goals and solving problems that are related to the usage of social media.

INTRODUCTION

Human being is a social animal and wants to socialize with others. Human beings want to get connected with family and friends and sometimes even with enemies also.

Socialization and getting connected with others is a need of any human being. Human beings can socialize broadly in two ways. First traditional way is face to face to interaction. Meeting people includes using all senses of human being and is the best way of socialization. Another second way is not meeting face to face. In second way, there can be two categories. People can get connected and socialize offline and online. Offline means not using internet and online means using internet. Offline includes post, telephone and mobile phone, while it includes using web technologies like social media, emails, chat, and internet telephony. It is very experienced truth that culture and therefore our society are always changing. They are affected by new thoughts, beliefs, new innovations, inventions and technologies. In this new era, technologies affect a lot. Computer, television, mobile phone, internet, satellite communication are the few examples those have affected the whole world and changed the society.

Internet is defined as “Network of Networks. Internet was initially used to communicate among connected computers. After development of WWW (World Wide Web), HTTP (Hyper Text Transfer Protocol) and HTML (Hyper Text Markup Language), lots of websites have been hosted on internet. Website is defined as “Collection of Web pages”. Social media websites provide service to get connected with others. Social media shows huge demand for socialization.

It is known that social media is the world leader in social media market used by more than 2.2 billion people. Social media is a medium that is facilitating its users for global interaction and sharing their ideas and experiences. Social media is social media that is in fact a Web based site which bring different people together in a virtual platform and ensure a deeper social interaction, stronger community and implementation of cooperation projects. Vast use of Social media around the globe has made it a new and important advertising platform, where businesses place their ads to reach their prospective customers. This is probably because social media allows businesses to target specific customer and promoting their product or services through effective advertisements. Many students are now influenced by these ads and because of that they started moving towards online advertisements such as social media, Instagram, etc. It is because they are getting their favorite brands at cheap prices. so it attracts them and they changed to buy from online by seeing these attractive advertisements.

METHODOLOGY

According to industrial research institute in research methodology, research always tries to search the given question systematically in our own way and find out all the answers till conclusion. For finding or exploring research questions, a researcher faces lot of problems that can be effectively resolved with using correct research methodology.

Sample size

The sample size in the study is 50.

Statistical tools

- Simple percentage method
- Chi- square test

PERCENTAGE METHOD

In this tool various percentage are identified analysis and they are presented by the way of Bar and Pie Diagrams to have better understanding of the analysis.

$$\text{Percentage} = \frac{\text{No. of Respondents}}{\text{Total Respondents}} \times 100$$

CHI-SQUARETEST

It is one of the simplest and widely used non-parametric test in statistical work. The quantity chi-square describes the magnitude of the discrepancy between theory and observation. Which is defined as

$$\text{Chi - Square} = \frac{\sum (oi - Ei)^2}{Ei}$$

O_i=Observed frequency, E_i=Expected frequency

In general, the expected frequency for any can be calculated from the following equations

$$F = \frac{RT \times CT}{N}$$

E=Expected frequency, CT=Column total,

RT=Row total, N =Total number of observations

ABSTRACT

Successful companies, including FABRIC companies dealing with certain problems, are conditioned by an optimal combination of material and nonmaterial factor directed towards employee motivation. Employee motivation is very important for the success of a company and its work processes. The quality concept of a business life encompasses aspects which influence employees being satisfied with the job, compensation system, working environment, respecting employee rights and needs. The satisfaction of employees with a job is based on social, economic and working conditions. The issue of earnings is one of the most important issues for the relation between employers and employees, which at the same time has a strong influence on social and economic development and social relations in society.

INTRODUCTION TO THE STUDY:

Textiles touch our daily lives, from casualwear to household textiles to more technically advanced materials used in medical applications to industrial products. Textiles are engineered to fulfill a purpose; the next generation of high-performance fibers will provide complex functionalities for technical applications. Textiles have been synonymous with human activity for thousands of years and as the years have progressed, the usage has become wider and more varied (McLaughlin and Hayes, cited in Jones & Styli's, 2013 Fibers have reshaped the way humans interact with the world around them. Humans have used fabrics in almost the same way to provide basis warmth and aesthetics (Chandler, 2016). Many people's perception of textiles is on traditional materials such as apparel, home

furnishings, curtains, and bedding. However, textiles have diversified and advanced into areas that affect our lives daily from automotive textiles to even more high-tech end uses such as smart materials that are able to react to the environment. High-performance products for outdoor pursuits such as camping, walking, and hiking are particularly big areas of the textile market.

- This study will help the top management to improve their labour Job Satisfaction in favourable for employees of METRO FABRICS AT KARUR.
- The Study covers the whole organization is taken into consideration and the survey is conducted among the workers through the Questionnaire and present study is restricted to Gray Grain Polymer Rubber Industry at Madurai and data is analysed based on the information provided by employees of the METRO FABRICS AT KARUR.

RESEARCH METHODOLOGY

A Research design is simply the framework or plan for a study. The design may be a specific presentation of the various steps in the process of Research. For this descriptive design was used. Descriptive research includes survey and fact-finding enquiries of different kinds. The major purpose of descriptive research is description of the state of affairs, as it exists at present. In this method the researcher has no control over the variables. He/She can only report what has happened and what is happening.

The methodology adapted to collecting information from a sample size of 100 respondents by using simple random sampling technique, in order to analyze and interpret the respondent's opinions and views with respect to the Job Satisfaction provided by METRO FABRICS AT KARUR. The entire study is based on both the primary data and Secondary data.

PRIMARY DATA:

For collecting the primary data, the questionnaire method was employed. Each respondent was given a questionnaire and they answered it and returned back in two weeks' time

Questionnaire: A Questionnaire has been prepared and distributed among the respondents (employees) for both executives and non-executives.

INTERVIEW: Personal Interview and interaction with the respondents (employees).

OBSERVATION: by observing the working environment.

SECONDARY DATA

For secondary data the researcher depends on various company records, websites and journals etc. The secondary data is that which have been already collected by someone or else which have been passed through statistical data can be categorized into two broad categories named published and unpublished statistics.

GENDER	NO OF RESPONDENT	PERCENTAGE
FEMALE	29	78.3%
MALE	21	21.7%

DATA SOURCE

Primary data was collected by the questionnaire based marked survey. Secondary data was obtained from journals, magazines newspapers, books and the internet.

Research Instrument

For doing the survey research, structured questionnaire with both open ended and close end equations were used.

Data Analysis:

The mode of survey was personal interview with the respondents during the filling up of the questionnaire.

Sampling Techniques:

The sampling used for this study was probability sampling. Since the study is only meant for certain specific categories within the total population, a stratified random sample was used. Three groups of categories have been taken into account viz. students. professionals and general public.

Sample Size:

A sample size of 50 respondents is used for the study.

DATA ANALYSIS AND INTERPRETATION:

Table shows the genders status of the respondent.

INTERPRETATION:

Most of the respondents are almost 78.3% female and less respondents are 21.7% male.

Majority of 78.3 % of the respondents are female.

GENDERS STATUS OF THE RESPONDENT

FINDINGS

- Majority 78.3 of the respondent are female.
- Majority 34% of the respondent are belong to 30-40 age
- Majority 34% of the respondent belongs to Graduated
- Majority 80% of the respondent are married
- Majority 28 % of the respondent are above 5 years
- Majority 68% of the respondent are satisfied with their teams
- Majority 56% of the respondent are satisfied for working their company
- Majority 66% of the respondent are satisfied with the holidays provided by the company
- Majority 62% of the respondent is feeling stress in their work
- Majority 58% of the respondent with the working hours
- Majority 60% of the respondent are agrees with that the company provides regard reward and recognition to the employees.
- Majority 40% of the respondent said slightly challenging in the work in that company.
- Majority 56% of the respondent are satisfied with the infrastructure facilities provided by the company
- Majority 36% of the respondent are between the level of income Rs5000-Rs10,000
- Majority 50% of the respondent are satisfied with the salary
- Majority 68% of respondent are working in production department

- Majority 68% of the respondents are comfortable to sharing their opinions
- Majority 58% of the respondent are feel secured in their job.

SUGGESTIONS:

- It would be beneficial to explore initiatives to promote gender diversity and inclusion within the workplace.
- The company could explore educational and skill enhancement programs to further empower and engage this group.
- To conduct a detailed analysis to identify the sources of stress and implement measures to alleviate or manage stress levels.
- Consider expanding or refining these programs based on employee feedback to further boost morale.
- Assess whether this is a positive or negative aspect and consider adjustments as necessary.
- Understand specific aspects contributing to satisfaction and potential areas for improvement of infrastructure
- To ensure fair compensation and identify potential financial wellness initiatives.
- Assess the unique challenges and satisfactions within this department to tailor strategies accordingly.

CONCLUSION:

The motivation factors have a strong influence on employee satisfaction resulting in any positive feelings that accompany human, who is trying to keep this state as long as possible, which leads to further efforts. Employee's satisfaction represents one of the most complex areas facing today's managers when it comes to managing their employees. Many studies have demonstrated an unusually large impact on the employee's satisfaction on the motivation of workers, while the level of motivation has an impact on productivity, and hence also on performance of business organizations. There is a considerable impact of the employees' perceptions for the nature of his work and the level of overall job satisfaction.

ABSTRACT

To investigate problems faced by food product exporters of India and propose solutions with the help of a questionnaire Design/Methodology/ Approach: The data obtained for this study were prepared from primary and secondary data. Primary data was collected through questionnaires with exporters of food products in Kabul province. Part of the interview part was conducted face-to-face, and some of the answers were collected from interviewees through the mail. The secondary data was obtained from reliable national and international organizations' websites

INTRODUCTION

Meaning of Export Management:

Management is a term commonly used in every activity. It means planning, organizing directing controlling and coordinating the specific activity so as to achieve its objective. Such activity may be related to purchase, production, and marketing and as well export. Export management means conducting the export activity in an orderly, efficient and profitable manner. Since the heart of each of each business is marketing, export management can be termed as export marketing management. Because if need to be managed efficiently so that the export should increase and export should get more profit and importer should get more satisfaction. Therefore, export management activity is growth oriented and dynamic in nature. Export marketing management and domestic marketing management are to aspects of the same coin total marketing management. However, export marketing management is more difficult and complicated as compared to domestic marketing due to several factor

such as three faced competition, varied regulations of different countries, language, If requires systematic approach for comprehensive oversea, marketing, requirements of foreign buyers, potential marketing opportunity and using and them tactfully for large – scale exporting

Definition of The Export Management:

The term export of management is rather difficult to define precisely as it dynamic is scope. Secondly, standard definition of the term export management is not available as it is an applied subject. Here the principles of management are applied to the management of export trade /marketing activities. However, it is possible to not some simple definition of export management such definition is as noted below:

OBJECTIVES OF THE STUDY

- To analyze the problems involved documentation process during export.
- To study the issues involved in communication.
- To know about quality issues during the export
- To study the problems involved logistics.
- To identify measures in order to resolves the issues.

SCOPE OF THE STUDY

To identify the major challenges faced by the logistics. To develop a framework for assessing communication issues while exporting. To suggest possible solutions for issues relating documentation process. To analyze the export performance and competitiveness in the international market. Evaluate the effectiveness of the proposed solutions. To provide recommendations for future improvements.

RESEARCH METHODOLOGY

Research methodology is a way of explaining how a researcher intends to carry out their research. It's a logical, systematic plan to resolve a research problem. A methodology details a researcher's approach to the research to ensure reliable, valid results that address their aims and objectives. It encompasses what data they 're going to collect and where from, as well as how it's being collected and analyzed.

Importance of Research Methodology

A research methodology gives research legitimacy and provides scientifically sound findings. It also provides a detailed plan that helps to keep researchers on track, making the process smooth, effective and manageable. A researcher's methodology allows the reader to understand the approach and methods used to reach conclusions. Having a sound research methodology in place provides the following benefits:

- Other researchers who want to replicate the research have enough information to.
- Researchers who receive criticism can refer to the methodology and explain their approach.
- It can help provide researchers with a specific plan of follow throughout their research.
- The methodology design process helps researchers select the correct methods for the objectives.
- It allows researchers to document what they intend to achieve with the research from the outset.

Types of research methodology

When designing a research methodology, a researcher has several decisions to make. One of them important is which data methodology to use, qualitative, quantitative or a combination of the two. No matter the type of research, the data gathered will be as numbers or descriptions, and researchers can choose to focus on collecting words, numbers or both. Here are the different methodologies and their applications:

Qualitative

Qualitative research involves collecting and analyzing written or spoken words and textual data. It may also focus on body language or visual elements and help to create a detailed description of a researcher's observations. Researchers usually gather qualitative data through interviews, observation and focus groups using a few carefully chosen participants. This research methodology is subjective and more time-consuming than using quantitative data. Researchers often use a qualitative methodology when the aims and

objectives of the research are exploratory. For example, when they perform research to understand human perceptions regarding an event, person or product.

Quantitative

Researchers usually use a quantitative methodology when the objective of the research is to confirm something. It focuses on collecting, testing and measuring numerical data, usually from a large sample of participants. They then analyze the data using statistical analysis and comparisons. Popular methods used to gather quantitative data are:

- Surveys
- Questionnaires
- Test
- Database
- Organizational Records

This research methodology is objective and is often quicker as researchers use software programs when analyzing the data. An example of how researchers could use a quantitative methodology is to measure the relationship between two variables or test a set of hypotheses.

DATA ANALYSIS AND INTERPRETATION

Chart representing AGE wise classification of respondents

From the above table, it is found that 3.8% of respondents are between age group below20, 55.8% respondents are between age group 20-30, 36% of respondents are between the age group 30-40, 3.8% respondents are between age group above40.

Inference

It is observed that (20-30) years of respondents are more when compared to the respondents with another category.

FINDINGS

- Majority of the respondents are males (65.4%)
- Most of the respondents are in the age group between20-30 (55.8%)
- Majority of the respondents are married (65.7%)
- Most of the respondents are in the graduates (42.3%)
- Majority of the respondents are worked in1-5years (42.3%)
- Most of the respondents are in getting salary (53.8%)
- Majority of the respondents are satisfied of their job (48.1%)
- Most of the respondents are said yes (61.5%)
- Majority of the respondents are satisfied of the quality (30.8%)
- Most of the respondents are said yes (53.8%)
- Majority of the respondents are good in the company engagement (36.5%)

- Most of the respondents are highly satisfied of the company development (76.9%)
- Majority of the respondents are affecting the language barrier in export organization said yes (63.5%)
- Most of the respondents are chosen yes in communication affecting export orders (59.6%)
- Most of the respondents are technical barriers in primary challenge of the organization (42.3%)
- Majority of the respondents are problems faced in export (55. %)
- Majority of the respondents are important of the cultural differences (53.8%)

SUGGESTIONS

- It is suggested to give training on communication to the employees in a regular basis so that the communication barriers can be sorted out.
- Alternatives for source of raw materials and transportation route need to be made in order to rectify issues regarding logistics.
- Excess purchase of raw materials can be avoided so that the quality of materials will not be deteriorated and cost of holding the materials can also be neglected
- Documentation procedures must be done in an appropriate manner based on the regulations. To do these employees who are expertise and have diversified knowledge about export documentation can be hired.

CONCLUSION

The study on problems faced by different areas of export highlights several challenges that exporters face in various regions. These challenges range from logistical issues to trade regulations, market access, and cultural barriers. To overcome these challenges, it is essential for exporters to understand the unique characteristics of each market and to develop tailored

strategies that take into account the specific challenges they face. Additionally, policymakers and industry stakeholders can work together to create more favorable trade conditions and address the systemic issues that hinder the growth of exports.

ABSTRACT

The physical appearance of clothing has been shown to influence consumers evaluation and purchasing decisions. However, favorable product attributes may not always translate into a purchase. In order to gain a deeper understanding of what constitute a consumer's mind, Levi's Jeans were used as the research method was employed to illuminate underlying consumer motives. In total, eighty male and female subjects aged from less than twenty-five to forty years participated in this study. The results of this study reveal that the preferred jeans choices were closely related to the fit of the garment , body image and appropriateness of use.

INTRODUCTION

Customer satisfaction is a term frequently used in marketing. It is a measure of how products and services supplied by a company meet or surpass customer expectation, Customer satisfaction is defined as "the number of customers, or percentage of total customers, whose reported experience with a firm, its products, or its services (ratings) exceeds specified satisfaction goals." Customer satisfaction provides a leading indicator of consumer purchase intentions and loyalty." Customer satisfaction data are among the most frequently collected indicators of market perceptions.

The goal for every company should be to make its customers satisfied. Satisfied customers will come again and might stay as customers for a longer period. It is important for the company to actually care and appreciate the customer. It is clear that if the company can make the customer satisfied the customer will come back a gain and the customers might tell some of their friends about the good service they got. So, through satisfied customers it is possible to save in marketing expenses

METHODOLOGY

According to industrial research institute in research methodology, research always tries to search the given question systematically in our own way and find out all the answers till conclusion. For finding or exploring research questions, a researcher faces lot of problems that can be effectively resolved with using correct research methodology.

Sample size

The sample size in the study is 80.

Statistical tools

- Simple percentage method
- Chi-square test

PERCENTAGEMETHOD

Simple percentage analysis is one of the basic statistical tools which is widely used in analysis and interpretation of primary data. It deals with the number of respondents response to a particular Questions in percentage arrived from the total population selected for the study.

$$\text{Percentage} = \frac{\text{No. of Respondents}}{\text{Total Respondents}} \times 100$$

CHI-SQUARETEST

It is one of the simplest and widely used non- parametric test in statistical work. The quantity chi-square describes the magnitude of the discrepancy between theory and observation. Which is defined as?

$$\text{Chi-Square} = \sum \frac{(O_i - E_i)^2}{E_i}$$

- Majority 53.75% of the respondents are using Levi's for good quality.
- Majority 41.25% of the respondents using Levi's Jeans for 1 year.

SUGGESTIONS

- A whole load of laundry when you can use a damp cloth after at least ten wears, it may be time to throw your jeans into the washer.
- Turning your jeans inside out prevents excessive fading and color loss.
- Check your pockets no one likes splotchy stains on their favorite pants.
- The indigo blue tint of your favorite jeans can wash out with harsh soaps. Preserve your favorite look with the right detergent.
- Choosing a cold-water spin cycle is added protection against fading and shrinking.
- Ever wonder where lint comes from its your clothes breaking down in the dryer.

CONCLUSION

The study mainly aims at knowing the customer satisfaction by Levi's Strauss .Most of the customers prefer Levi's Strauss & CO. ,for their prompt delivery and proximity.

The service provided by the company is the key factors for the success of the product as well as the company in this industry. Levi's Strauss & Co., has been able to make an impression in the market by delivering high quality products and value added-services. The

company has a service activity division supporting the customers and constantly monitoring the performance of service in the company and taking action.

The organization should also give importance to the suggestions and recommendations so as to maintain support of present customers to create new customers.

ABSTRACT

Driver's drowsiness is the major problem that causes road accidents. Unlike normal facial expression, drowsiness is defined to be a condition of exhaustion, where the expression of the face is different from usual. The important steps in detecting drowsiness are face detection and expression detection. When the detection occurs that time the hazard lights are activate automatically to warn other drivers that the vehicle is a temporary obstruction. Also we have proposed new safety method using Ultrasonic sensors. It is used to detect the obstacles in which by using transmitter and receiver signals. The barrier principle determines the distance from the sensor to the reflector (Retro-Reflective Sensor) or to an object (Through-Beam Sensor) in the measuring range. The distance measurement using ultrasonic sensors to detect obstacles and their distances. Once the obstacle has been detected and safe separation distance is reached, the vehicle will automatically get stopped and also shared control concept for lane keeping assist (LKA) systems of intelligent vehicles. The core idea is to combine system perception with robust control so that the proposed strategy can successfully share the control authority between human drivers and the LKA system. This shared control strategy is composed of two parts, namely an operational part and a tactical part. Two local optimal-based controllers with two predefined objectives (i.e., lane keeping and conflict management) are designed in the operational part. The control supervisor in the tactical part aims to provide a decision making signal which allows for a smooth transition between two local controllers. The control design is based on a human-in the-loop vehicle system to improve the mutual driver-automation understanding, thus reducing or avoiding

the conflict. In particular, the control design is formulated as an LMI optimization which can be easily solved with numerical solvers. The effectiveness of the proposed shared control method is clearly demonstrated through various hardware experiments with human drivers. Its controls the steering and to go on the straight road.

INTRODUCTION

The report noted that Tamil Nadu has maintained the top position in the number of accidents on national highways for the fifth continuous year since 2018. Further, the state also recorded a total of 64,105 road accidents in 2022, an increase of 15.1 per cent from 2021. In recent years, an increase in the demand for modern transportation necessitates a faster car-parc growth. At present, the automobile is an essential mode of transportation for people. In 2017, a total of 97 million vehicles were sold globally, which was 0.3% more than that in 2016. In 2018, the global total estimation of the number of vehicles being used was more than 1 billion. A report by the National Highway Traffic Safety Administration showed that a total of 7,277,000 traffic accidents occurred in the United States in 2016, resulting in 37,461 deaths and 3,144,000 injuries. In these accidents, fatigue driving caused approximately 20% 30% traffic accidents.

Every time we open the newspaper there are news articles and cases about road accidents happening all over the world due to the driver falling asleep behind the wheel. Car accidents are a major cause of death claiming about 1.3 million deaths every year, and each year this figure is increasing [1]. Statistics have suggested that this could be even more deadly than drunk driving [2]. In India alone, drowsy driving is a cause of 40% of the total accidents in the country [3]. This is a very huge problem because a driver being drowsy. Many people who prefer booking cabs or rides at night are at a higher risk if they are allotted a driver who is in a sleepy or a drowsy state.

Many industries (manufacturing, logistics, transport, emergency ambulance, and similar) run their operations 24/7, meaning their workers work in shifts. Working in shifts causes

misalignment with the internal biological circadian rhythm of many individuals, which can lead to sleeping disorders, drowsiness, fatigue, mood disturbances, and other long-term health problems [4-7].

LITERATURE SURVEY

1. This paper presents a novel shared control concept for every time we open the newspaper there are news articles and cases about road accidents happening all over the world due to the driver falling asleep behind the wheel. Car accidents are a major cause of death claiming about 1.3 million deaths every year, and each year this figure is increasing. (Ref [1]).
2. In this paper, statistics have suggested that this could be even more deadly than drunk driving. (Ref [2]).
3. In India alone, drowsy driving is a cause of 40% of the total accidents in the country. This is a very huge problem because a driver being drowsy. Many people who prefer booking cabs or rides at night are at a higher risk if they are allotted a driver who is in a sleepy or a drowsy state. (Ref [3]).
4. Many industries (manufacturing, logistics, transport, emergency ambulance, and similar) run their operations 24/7, meaning their workers work in shifts. Working in shifts causes misalignment with the internal biological circadian rhythm of many individuals, which can lead to sleeping disorders, drowsiness, fatigue, mood disturbances, and other long-term health problems. (Ref [4-7]).
5. This paper presents a novel shared control concept for lane keeping assist (LKA) systems of intelligent vehicles. The core idea is to combine system perception with robust control so that the proposed strategy can successfully share the control authority between human drivers and the LKA system. (Ref [8]).
6. Although technological advances have been significantly made to improve the performance of ADAS, the control issue of active safety systems being able to share the driving responsibility with human drivers still remains challenging. (Ref [9-10]).
7. A Ultrasonic sensor is used to detect the obstacles. In the Ultrasonic sensor there is a transmitter and receiver signals which is used to detect the vehicle. A Ultrasonic setup is placed in front of vehicle and that setup consists of an emitter and a receiver.

Ultrasonic emitter always emits the ultrasonic waves, whenever a obstacle is detected then wave gets reflected and receiver receives the signal. Reflected wave sends the signal to the Aurduino Nano from that based upon distance of object it actuates the brakes and then it will continue moving of the vehicle. (Ref [11]).

EXISTING SYSTEM

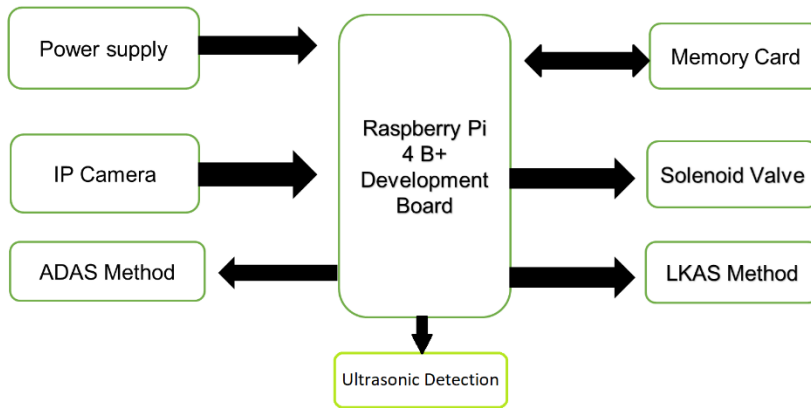

This paper presents the development of a solution to detect a driver's drowsiness in real time and issue alerts to avoid possible traffic accidents. In particular, an analysis of the methods used for the detection of drowsiness by computer vision is performed, focusing on the use of facial reference points. Distraction, drowsiness, tiredness, speeding and fatigue are the main causes of accidents and, precisely, advanced driver assistance systems ADAS help reduce these serious human errors. In this system it will only detect and indicates alarm then it will slow the speed of the vehicle.

PROPOSED METHOD

Driver drowsiness is a common cause of fatal traffic accidents. In this study, Ultrasonic sensor is used to detect the obstacles. In the Ultrasonic sensor there is an transmitter and receiver signals which is used to detect the vehicle. A Ultrasonic setup is placed in front of vehicle and that setup consists of an emitter and a receiver. Ultrasonic emitter always emits the ultrasonic waves, whenever a obstacle is detected then wave gets reflected and receiver receives the signal. Reflected wave sends the signal to the Aurduino Nano from that based upon distance of object it actuates the brakes and then it will continue moving of the vehicle. A driver assistance system with a dual control scheme is developed; it attempts to perform simultaneously the safety control of the vehicle and identification of the driver's state. The assistance system implements partial control in the event of lane departure and gives the driver the chance to voluntarily take the action needed. If the driver fails to implement the steering action needed within a limited time, the assistance system judges that "the driver's understanding of the given situation is incorrect" and executes the remaining control. We used a driving simulator equipped with the assistance system to investigate the effectiveness of identifying driver drowsiness and preventing lane departure accidents and continue

driving by Lane Keeping Assist System method. This process will help to continue the travel without accidents with medium speed of the vehicle.

MODULE DESCRIPTION

Power Supply:

SMPS

A Switched Mode Power Supply (switching-mode power supply, switch-mode power supply, switched power supply, SMPS, or switcher) is an electronic power supply that incorporates a switching regulator to convert electrical power efficiently. Like other power supplies, an SMPS transfers power from a DC or AC source (often mains power) to DC loads, such as a personal computer, while converting voltage and current characteristics. Unlike a

linear power supply, the pass transistor of a switching-mode supply continually switches between low-dissipation, full-on and full-off states, and spends very little time in the high dissipation transitions, which minimizes wasted energy. Voltage regulation is achieved by varying the ratio of on-to-off time (also known as duty cycles). In contrast, a linear power supply regulates the output voltage by continually dissipating power in the pass transistor. Switching regulators are used as replacements for linear regulators when higher efficiency, smaller size or lighter weights are required. They are, however, more complicated; their switching currents can cause electrical noise problems if not carefully suppressed, and simple designs may have a poor power factor.

Raspberry Pi 4 B+:

The Raspberry Pi 4 Model B is the latest version of the low-cost Raspberry Pi computer. The Pi isn't like your typical device; in its cheapest form it doesn't have a case, and is simply a credit-card sized electronic board of the type you might find inside a PC or laptop, but much smaller. The Raspberry Pi 4 can do a surprising amount. Amateur tech enthusiasts use Pi boards as media centres, file servers, retro games consoles, routers, and network-level ad-blockers, for starters. However that is just a taste of what's possible. There are hundreds of projects out there, where people have used the Pi to build tablets, laptops, phones, robots, smart mirrors, to take pictures on the edge of space, to run experiments on the International Space Station and that's without mentioning the more wacky creations teabag dunker anyone. With the Pi 4 being faster, able to decode 4K video, benefiting from faster storage via USB 3.0, and faster network connections via true Gigabit Ethernet, the door is open to many new uses.

IP Camera:

An Internet Protocol camera, or IP camera, is a type of digital video camera that receives control data and sends image data via an IP network. They are commonly used for surveillance but unlike analog Closed-Circuit Television (CCTV) cameras, they require no local recording device, only a local area network. Most IP cameras are webcams, but the term IP camera or net cam usually applies only to those that can be directly accessed over a network connection, usually used for surveillance. Some IP cameras require support of a central Network Video Recorder (NVR) to handle the recording, video and alarm management. Others are able to operate in a decentralized manner with no NVR needed, as the camera is able to record directly to any local or remote storage media.

**Memory Card:**

A memory card or memory cartridge is an electronic data storage device used for storing digital information, typically using flash memory. These are commonly used in portable electronic devices, such as digital cameras, mobile phones, laptop computers, tablets, PDAs, portable media players, video game consoles, synthesizers, electronic keyboards and digital pianos, and allow adding memory to such devices without compromising ergonomic, as the card is usually contained within the device rather than protruding like USB flash drives.

Web Server

A web server is a computer system that processes requests via HTTP, the basic network protocol used to distribute information on the World Wide Web. The term can refer to the entire system, or specifically to the software that accepts and supervises the HTTP requests.

The primary function of a web server is to store, process and deliver web pages to clients. The communication between client and server takes place using the Hypertext Transfer Protocol (HTTP). Pages delivered are most frequently HTML documents, which may include images, style sheets and scripts in addition to text content.

Open CV:

Open CV (Open Source Computer Vision Library) is a library of programming functions mainly aimed at real-time computer vision. Originally developed by Intel, it was later supported by Willow Garage (which was later acquired by Intel). The library is cross-platform and free for use under the open-source Apache 2 License. Starting with 2011, Open CV features GPU acceleration for real-time operations.

Solenoid Valve:

A fuel shutoff solenoid is an electromagnetically-operated valve used to remotely cut the fuel supply to an engine. The solenoid typically consists of a valve body with an integral solenoid assembly connected to the valve stem. When the solenoid is energized, the motion of its plunger retracts the spring-loaded valve poppet from its seat, allowing fuel to pass through the valve. When the solenoid is deactivated, the valve spring pulls the poppet back onto its seat effectively cutting the flow of fuel. The shutoff solenoid may be manually activated or be part of an automated engine management system.

ULTRASONIC SENSOR:

The ultrasonic sensor is used to detect the lane on the road and then the vehicle will follow the centre inbetween the lane. The steering will be automatically controlled by the LKAS process, Then it will be keep going for few distance or upto the drowsy driver will be alright and take control the steering.

RESULT

This paper has discussed an assistance system that is effective for preventing of sleep-related vehicle accidents. A multilayered assistance with a dual control scheme, which could assist in reducing sleep-related accidents, was presented. The assistance system judges the driver's state in a multilayered way through the interaction between the driver and the assistance system in addition to executing the first- and second-stage controls to maintain safety.

The assistance system assisted the driver only when almost really needed in lane departure situations and braking by Ultrasonic sensor.

ABSTRACT

To accomplish this purpose, this project provides a novel method that makes use of Li-Fi technology, an Arduino Uno microcontroller, and a suite of sensors. For comprehensive health monitoring, the system includes an emergency button, a body temperature sensor, and a gyro sensor. The data acquired by these sensors is relayed to a receiver through an underwater Li-Fi channel, where it is analysed and displayed on an LCD screen. In the event of an emergency, the mechanism sounds a bell to notify the surface team. This technology has the potential to dramatically improve diver safety and enable fast reaction to urgent circumstances.

Due to the limitations presented by RF-based technological advances, the underwater environment poses special obstacles for communication and monitoring. Underwater communication is made possible by Li-Fi, a wireless technology that transmits data via light waves. With the help of Li-Fi technology, this project attempts to build a reliable system that tracks a diver's vital signs, such as body temperature and movement, and transmits that information to a surface station.

INTRODUCTION

The undersea environment provides a unique and demanding backdrop for human activity, particularly in diving settings. Communication and health monitoring are key

components of guaranteeing scuba divers' safety and well-being in such circumstances. Traditional radio-frequency (RF) communication systems are severely limited in underwater environments due to radio wave attenuation and dispersion. Underwater Li-Fi Communication has developed as a possible option in answer to these issues.

OBJECTIVES

Li-Fi, short for Light Fidelity, is a cutting-edge wireless communication technology that transmits data using visible light or near-infrared spectrum. In contrast to typical RF-based systems, Li-Fi has the ability to provide high-speed, secure, and dependable communication in situations where existing approaches struggle. The inherent benefits of light waves, which do not experience the same propagation limitations as radio waves underwater, are taken advantage of by this technique.

This project's main objective is to put in place a cutting-edge underwater Li-Fi communication system made exclusively for keeping track of scuba divers' well-being. To offer thorough real-time health information for scuba divers, this system integrates a number of sensors, including an emergency button, a body temperature sensor, and a gyro sensor. This device claims to revolutionise how scuba divers' health is tracked during underwater operations by utilising an Arduino Uno micro controller for data processing and control. Timely communication is essential in emergency situations. The device includes an emergency button that enables scuba divers to rapidly inform the surface team in case of trouble in order to allay this worry. The capacity to communicate instantly can make the difference between a situation being controllable and developing into a crisis.

The system creates an effective and quick communication channel that surpasses the constraints of conventional RF-based technologies in submerged environments by utilising Li-Fi transmitters and receivers. This not only speeds up the transfer of crucial health data, but also enables for rapid response and intervention in the event of an emergency. This project represents an important step forward in underwater safety and operating efficiency. We hope to set a new standard in diver health monitoring and communication by integrating cutting-edge Li-Fi technology with a carefully selected array of sensors and a durable microprocessor. The parts that follow will go over the technical intricacies, components, and operating features of this revolutionary Underwater Li-Fi Communication system.

RELATED WORK

[1] The planned technique consists of transmission and receiving section. The transmission section detects the abnormalities moon-faced by the diver and therefore the information is transferred by exploitation the medium referred to as light-weight fidelity. In receiving section the sunshine signal is reborn within the sort of electrical signal and therefore the information is made within the sort of audio. This can be what we've accomplished with wireless underwater communications.

[2] Diving has come a common way of performing exploration in the submarine-living world. One of the major problems with diving is the health issues faced by the divers during diving and there comes the need for covering the diver's health. This paper substantially utilizes Li-Fi (Light Fidelity) data transfer, this system provides divers with health monitoring systems, fear buttons body temperature, and body position.

[3] Diving has become a common way of performing research in the underwater living world. One of the major problems with diving is the health issues faced by the divers during diving and there comes the need for monitoring diver's health. This paper mainly focuses on the health monitoring systems for divers by transferring the data using Li-Fi (Light Fidelity).

[4] In this paper information correspondence, controlling the gadgets and just as transmission of sound with assistance of noticeable light is accomplished. In an ordinary life, Wi-Fi is utilized as reasonable innovation yet the radiations produced from these are perilous for strength of human in this way Lifi is liked to the remote advancements like Wifi. Lifi sends the information by utilizing light.

[5] Since communications in the Underwater Wireless Sensor Networks (UWSNs) have limited resources and capabilities, designing an efficient and reliable Media Access Control (MAC) protocol for UWSNs faces many challenges. UWSNs have limited bandwidth, power, memory, long propagation delay, high Bit Error Rate (BER), and unreliable communication.

[6] Energy consumption is a critical issue in the design of wireless underwater sensor networks (WUSNs). Data transfer in the harsh underwater channel requires higher transmission powers compared to an equivalent terrestrial-based network to achieve the same range. However, battery-operated underwater sensor nodes are energy-constrained and require that they transmit with low power to conserve power.

[7] This paper proposes an application of Li-Fi network in the hospital for monitoring the patient's conditions such as temperature, pressure, heartbeat, glucose level, and respiratory conditions using respective sensors. The collected data from the sensors is transmitted to the sink, and further these data are processed using microcontroller and sent to display unit in the form of graphs or charts. Based on the concept of visible light communication, a prototype model is built with the PIC microcontroller and basic sensors as peripherals and tested it's working.

[8] In order to solve this many wireless technologies have been proposed to monitor the patient's condition using different sensors but these wireless schemes are harmful for patients/infants and can even interface with medical devices. In order to develop hospital friendly monitoring system, Li-Fi based health monitoring-based system has been proposed which measure the heart rate, temperature and motion in case of infants and the data is continuously displayed on LCD. In case of any abnormalities, the relevant staff will be notified.

[9] This causes inefficiencies and other issues for a variety of applications, such as ocean exploration and submarine-to-plane communication. To start, there are two choices of underwater communications: Hardwired uses a cable to transfer the data, and wireless uses water for communications. Mostly communicate with land side to transfer their emergency situation we accompanied it.

[10] Their navigation system is much more challenging than that of land-based applications, due to the lack of connected networks in the marine environment. On the other hand, due to the latest developments in neural networks, particularly deep learning (DL), the visual recognition systems can achieve impressive performance. Computer vision (CV) has especially improved the field of object detection.

EXISTING SYSTEM

Constant monitoring of patient's health condition in hospital is either manual or wireless fidelity (Wi-Fi)-based system. Wi-Fi-based system becomes slow in speed due to exponentially increased scalability. In this scenario, light fidelity (Li-Fi) finds the places wherever Wi-Fi is applicable with additional features of high speed data network. Apart

from the speed factor, Li-Fi is more suitable in hospital application for monitoring the patient's conditions without frequency interference with human body.

PROPOSED SYSTEM

A cutting-edge fusion of cutting-edge technology is used in the Underwater Li-Fi Communication system created for monitoring scuba divers' health. At its core, this system takes advantage of Li-Fi's distinct benefits by transmitting data via the visible or near-infrared spectrum. This development is a game-changer for underwater situations, where conventional radio-frequency (RF) communication meets tough obstacles because of the water's radio wave absorption and scattering.

Critical health metrics are continuously and in real-time monitored thanks to the inclusion of an emergency button, a body temperature sensor, and a gyro sensor. By serving as a direct line of communication between the diver and the surface team, the emergency button enables immediate crisis alerting. The the Arduino Uno microcontroller, which orchestrates the flow of data from the sensors and controls communication with the Li-Fi transmitter and receiver. It serves as the system's brain, handling data interpretation, communication protocols, and alarm triggering. Its adaptability and programmability make

it an excellent choice for this application, allowing for the easy integration of multiple components.

The Li-Fi transmitter and receiver serve as the communication system's backbone. The processed sensor data is converted into light signals by the transmitter, which are subsequently sent across the aqueous medium. This technique has considerable advantages over standard RF-based communication in terms of data transmission speed and security. Strategically placed receiver collects light signals and sends the information to Arduino Uno for additional processing. The timely delivery of health information to the surface team depends on this trustworthy and effective communication link.

An LCD monitor is built within the system to give scuba divers a user-friendly interface. This display presents essential health information in a simple and understandable manner. Scuba divers can perform quick assessments of their own health, enabling them to make wise choices while engaging in underwater activities. Additionally, a bell is activated in an emergency to further notify the surface team. By adding an extra layer of notification with this auditory signal, we can make sure that no urgent issue goes overlooked.

EXPLANATION

The emergency button is an essential component of the system, allowing scuba divers to signal for rapid assistance or alert the surface team in the event of a problem. When pressed, it initiates immediate connection with the surface station, enabling for quick response in emergency situations.

The body temperature sensor is a precision gadget that measures the core body temperature of the diver. It gives real-time data on the diver's physiological state, assisting with the detection of overheating and hypothermia. This information is critical for the diver's safety during extended underwater tasks. The gyro sensor, sense the scubas movement to update on the microcontroller

The system's central processing unit is the Arduino Uno microcontroller. Receiving data from the various sensors, processing it, and managing communication with the Li-Fi transmitter and receiver are its duties. The microcontroller furthermore carries out the logic for deciphering emergency signals from the button and turning on the alarm system.

A specialised component that turns processed sensor data into modulated light signals is the Li-Fi transmitter. These signals convey encoded data and are transferred via the water medium. The transmitter overcomes the limits of standard RF communication in underwater situations by utilising visible light or near-infrared spectrum, enabling a high-speed and secure data transfer channel.

The Li-Fi receiver is strategically placed to receive the light signals transmitted by the Li-Fi transmitter. It is in charge of demodulating and retrieving encoded data, which is

subsequently sent to the Arduino Uno microcontroller for processing. The sensitivity and precision of the receiver are critical for maintaining reliable transmission.

Scuba Divers can obtain their real-time health data using the LCD's user-friendly interface. It shows crucial metrics like body temperature and activity level, enabling scuba divers to keep an eye on their own wellbeing while performing underwater operations. This element is essential for empowering and preserving scuba divers' knowledge.

When an emergency arises, the buzzer can be used as an auditory alert system. It generates a distinct sound when activated to notify the surface crew, adding another layer of notice to the LCD display's visual cues. This auditory indication is necessary to make sure that urgent problems are handled right away.

HARDWARE REQUIREMENTS

POWER SUPPLY UNIT

A power supply unit (PSU) is an important component in electronic devices that converts electrical power from an external source (such as a wall outlet or a battery) into a form that can power the device's internal components. It supplies the required voltage, current, and stability to ensure that electronic circuits operate properly.

A power supply unit frequently incorporates circuitry to adjust the voltage output. This ensures that, even if the input voltage varies, the voltage provided to the device remains consistent. This is critical for the reliable operation of delicate electrical components.

Power supplies are often equipped with safeguards that limit the amount of electricity that can be pulled from them. This avoids overloading and potential damage to the power source or associated devices.

Figure No .4 Power Supply Unit

Some power supplies have numerous outputs with varying voltage and current ratings. This is useful for powering devices with varying power needs.

ARDUINO UNO

In the field of electronics and embedded systems, the Arduino Uno microcontroller board is a flexible and popular choice. It was created by Arduino and is based on the ATmega328P microcontroller, providing a robust yet user-friendly platform for many projects. As a result of the board's numerous digital and analogue input/output pins, it can connect to a large range of sensors, actuators, and other parts. Its simplicity in programming, which can be accomplished using the Arduino Integrated Development Environment (IDE), which streamlines the process with a user-friendly interface, is one of its distinguishing qualities. This makes it a fantastic option for both novice and seasoned developers.

The Arduino Uno's adaptability and flexibility make it suited for a wide range of applications. Prototyping, automation, robotics, IoT (Internet of Things), and educational projects are all typical uses for it. Its compatibility with a large selection of shields (add-on boards) and libraries makes it simple to extend its capabilities, allowing for the smooth integration of extra functionalities. Furthermore, its low cost and widespread availability make it an appealing option for both enthusiasts and educational organisations. The Arduino Uno, with its user-friendliness, expandability, and robustness, remains a cornerstone in the field of embedded electronics, enabling innovation and creativity in innumerable projects throughout the world.

LIFI TRANSMITTER

A Li-Fi transmitter is a device that transmits data wirelessly by using light waves, often in the visible or near-infrared spectrum. The wireless communication system known as Li-Fi, or "light fidelity," has a number of benefits over more established radio-frequency (RF) communication techniques. A Li-Fi transmitter modifies data onto light waves, which a Li-Fi receiver may pick up and demodulate in order to extract the data that was sent. High-

speed and secure data transfer is made possible by this technology, which is especially helpful in conditions where RF communication may be difficult, as in the water or in places with electromagnetic interference. Li-Fi transmitters are used in a variety of industries, such as secure data transmission in delicate settings, indoor location, and underwater connection.

Figure No .6 Li-Fi Transmitter

LIFI RECEIVER

A Li-Fi receiver is a device that captures and decodes modulated light signals sent by a Li-Fi transmitter. Li-Fi, or Light Fidelity, is an innovative wireless communication technology that transmits data using visible light or near-infrared spectrum. The receiver is outfitted with specialised sensors or photodetectors that detect light signals and transform them back into electrical data. This enables the receiver to retrieve the data sent by the Li-Fi transmitter. Li-Fi receivers are critical in providing high-speed and secure wireless communication, particularly in areas where standard radio-frequency (RF) transmission may be limited. They are used in fields such as underwater communication, indoor positioning systems, and secure data transfer in sensitive environments.

Figure No .7 Li-Fi Receiver

EMERGENCY BUTTON

Figure No .8 Emergency Button

The emergency button in the Underwater Li-Fi Communication system for monitoring scuba divers' health is a key safety element that allows scuba divers to signal distress or emergency circumstances to the surface team quickly and effectively. This button, which is placed within easy reach of the diver, provides a direct and immediate way of alerting the surface team in the event of an emergency. When pressed, it sends an emergency signal via the Li-Fi communication channel, which is subsequently received and processed by the surface station. This ability to respond quickly is critical in underwater conditions, where quick action can be the difference between a controllable issue and a potentially life-threatening emergency.

TEMPERATURE SENSOR

Figure No .9 Temperature Sensor

A specialised electronic gadget is used in the Underwater Li-Fi Communication system for scuba divers' health monitoring to assess the underwater environment's ambient temperature. This sensor is essential for giving the diver's body temperature, an important physiological parameter, in real-time data. The sensor assists in ensuring that the diver stays within a safe temperature range throughout the underwater operation by continuously

measuring the diver's body temperature. Based on concepts like resistance change, voltage variation, or semiconductor properties in reaction to temperature fluctuations, the temperature sensor functions. It offers precise measurements that are accurate, enabling the identification of even minute variations in the diver's body temperature. This data is then communicated to the surface station via the Li-Fi communication channel, where it can be monitored and analysed by the surface team.

GYRO SENSOR

A gyro sensor, often known as a gyroscope sensor, is a device that measures rotational motion or angular velocity. It gives information on the rate of rotation about a specific axis. Gyro sensors are essential in a wide range of applications, including aerospace, vehicle stability control systems, electronic devices, and robotics.

These sensors operate on the basis of angular momentum. They usually have a rotating mass that resists changes in orientation. The Coriolis effect causes the spinning mass to deflect when the sensor experiences angular motion, and this deflection is then measured to calculate the rate of rotation. Gyro sensors are essential components of electronic devices like smartphones for functions including screen orientation, gaming, and camera image stabilisation. They provide for fine control of orientation and movement in robotics. Gyro sensors are essential parts of navigation systems in aircraft applications, ensuring precise location and heading data. In a wide range of dynamic systems, gyro sensors are essential for supplying stability and control.

Figure No .10 Gyro Sensor

LCD

Figure No .11 LCD

A liquid crystal display, or LCD, is a flat-panel electronic visual display technology that is widely used in devices such as televisions, computer monitors, and different mobile devices. It works by modifying the characteristics of liquid crystals to control the passage of light and so create images or text. LCDs are substantially thinner and lighter than classic cathode ray tube (CRT) displays, making them very adaptable and ideal for a wide range of applications. They use less power, produce less heat, and have exceptional visual clarity. LCDs are made up of pixels, each of which contains sub-pixels that emit red, green, and blue light, resulting in a full range of colours. This technology has become a mainstay of modern visual displays, revolutionising how information is delivered and viewed in a variety of industries.

BUZZER

Figure No .12 Buzzer

When an electrical current is passed through a buzzer, it produces an audible sound. It is often made up of a piezoelectric element or an electromagnetic coil, as well as a diaphragm. The buzzer emits a distinct sound or tone when actuated.

A buzzer is included as a crucial alerting device in the "Underwater Li-Fi Communication for Monitoring Scuba Divers' Health" system. The Arduino Uno microcontroller activates the buzzer to provide a loud and recognisable sound in an emergency or when the diver

presses the emergency button. The purpose of this auditory signal is to provide an additional layer of notification to the surface team about the critical underwater condition. It guarantees that the diver's distress signal is adequately relayed even in difficult underwater circumstances, enhancing their safety and hastening any required aid or reaction. A crucial safety component that improves the overall efficiency and dependability of the communication and monitoring system for scuba divers is the buzzer.

CONCLUSION

Finally, the Underwater Li-Fi Communication system designed to monitor scuba divers' health marks a significant advancement in underwater safety and health monitoring. This system provides a comprehensive solution for real-time health monitoring and emergency communication in demanding underwater situations by integrating cutting-edge Li-Fi technology with a suite of sensors, an Arduino Uno microcontroller, and other critical components.

The presence of an emergency button, a body temperature sensor, and an gyro sensor ensures that vehicle data are continuously monitored, allowing for fast response in the event of a crisis. The implementation of Li-Fi technology provides a dependable and fast communication channel that outperforms previous RF-based approaches, considerably improving diver safety. This novel device not only promises to transform how scuba divers' health is handled during underwater operations, but it also establishes a new benchmark for safety regulations in high-risk areas. The Underwater Li-Fi Communication system holds enormous promise for the future of underwater exploration and operations, with the opportunity for further developments and applications.

ABSTRACT

The Zirconia-based ceramics are widely used in Automobile and Aerospace sectors because of their High-end mechanical properties such as improved hardness, durability, and strength characteristics. Many researches show that the machining of these composites is much harder than the traditional machining processes. Even though the machining was done but ended up with an unfinished surface finish, overcut, a high rate of tool wear, less material removal rate, huge time consumption, and damages. These difficulties become a great challenge to industrialists and researchers. The study is concerned with the machining performance of the ECDM while doing the machining of Zirconia composite by determining the multi-response parameters, the optimal combination of parameter levels. As response parameters, MRR and TWR were used. Experiments were carried out in accordance with the Box Bhenken Design. And response measurements were analysed. The outcomes showed

that for simultaneously managing multiple response characteristics, applied voltage (V) is the most important governing input parameter, followed by Duty Cycle (%) and electrolyte concentration (wt%).

INTRODUCTION

Electrochemical discharge machining is a revolutionary and extremely promising hybrid machining method that combines the concepts of electrical discharge machining (EDM) with electrochemical machining (ECM). In this method, material is removed through chemical etching and thermal spark erosion, followed by evaporation. The work material is removed as a result of the electrical discharge's intense thermal heating and melting of the substance. The chemical activity contributes to the achievement of the higher surface quality by causing further finer material removals. The combined effects of local Joule heating brought on by thermal heating are what cause the material loss in ECDM.[2-3] However, creation of microchannel in material like glass and ceramic through conventional techniques is a tedious task due to elevated material properties like high hardness and brittleness [4] and therefore non-traditional machining methods are called for machining these glasses.

To produce micro-features in non-conductive materials such as pyrex glass, borosilicate glass, silica glass, silicon wafers, quartz, and ceramics, the electro chemical discharge machining (ECDM) process is currently emerging as a cost effective substitute for ultrasonic machining, laser ablation, and wet chemical etching [5]. Various process factors are explored in this study, and it is predicted that the electrolyte content reduces tool wear while boosting MRR. To obtain the highest material removal rate, the electrolyte concentration is increased to three levels in this study. [6] To optimize, they used various design of trials, such as the Taguchi design and the GA algorithm, in this work. In this study, we employed response surface methods to design experiments; [7] They employed ECDM to mill a glass workpiece using four parameters such as voltage, duty factor, electrolyte concentration, and temperature in this experiment. They employed response surface methods to construct trials, and they discovered that MRR increased with voltage and temperature. One of the critical

machine configurations in this process is keeping the NaOH electrolyte stationary rather than in circulation. This experiment [8] demonstrates that a higher MRR is obtained when the electrolyte is in a stagnant position, thus we conducted the same [9] while milling.

METHODS AND MATERIALS

Design of Experiments

To create a hole in the zirconia composite plate, the material is removed using the stainless-steel tool. Electrolytes are preserved in a stagnant state in the stationary instrument. Three distinct characteristics, such as the applied voltage, duty cycle, and electrolytic concentration, have an influence on the material removal rate.

The Process parameters

The process parameters ranges for the experiments are given below:

Selection of Machining Parameters

To machine the hard to machine materials such as ceramics, the aforementioned process variables are tabulated in Table.1 and which were chosen based on trial study results.

Material for Work piece

Zirconia-silicon nitride composite is considered to be one of the hardest and most corrosive-resistant materials. The zirconia composite is a material with incredible features such as high resistance to indentation, high resistance to wear, excellent thermal stability,

and improved chemical resistance, and it is also mentioned that these composite is strongly suggested to make wear-resistant coating. Furthermore, they discovered that MRR increases with increasing applied voltage and that overcut concerns were also highlighted [10]. The research's objective is to raise MRR while lowering TWR.

Electrochemical Discharge Machining (ECDM) Process

In their experimental study, they employed the ultrasonic machining [11] method and discovered that increased voltage contributes to tool wear [12] and the abrasive sludge creates destruction of the surface area. In this activity, the ECDM is employed to safeguard against un even machining caused by an abrasive sludge. Figure 1 represents the experimental layout for the ECDM.

Figure 1: Machining setup

The work piece is placed in the process chamber, which is previously filled with NaOH till it covers over the work piece surface. A tool holder is attached to the stainless steel tool. The work table is moved in the X and Y directions using a hand wheel to machine the material.

RESULTS AND DISCUSSION

The work piece material is kept into the machining chamber as seen in Figure 2. The work piece are placed just below the electrolyte level and where the spark is created. Electrification

Discharge will release when the machining process starts, the electrolyte around the tool debases as a result of the reaction, creating gas bubbles. The bubbles then release the pressure energy, which leads to the material removal. Due to the spark, the electrode wears out and becomes contaminated. As a result, a brand-new electrode and brand-new electrolytic concentration solution are utilised for every experiment.

The MRR and TWR for the machining of zirconia composites are displayed in Table.2. To determine the rate of material removal and rate of tool wear, the work piece and tool were inspected both before and after machining.

CONCLUSION

With the help of ECDM process, non-conductive materials including glass, ceramics, polymers, etc. can be machined effectively. These findings are derived from experimental research using zirconia composite machining

1. The ECDM technology makes it feasible to efficiently machine electrically inert materials including glass, ceramic and polymer, etc.
2. The MRR and TWR of zirconia composite are greatly impacted by voltage in this followed by duty cycle study.
3. Voltage is the most influencing factor in the MRR, followed by electrolyte concentration.
4. Voltage plays a major role then followed by duty cycle in the TWR.
5. Optimized MRR and TWR are found at electrolyte concentration is 10% wt., the applied voltage is 100 V, and the duty cycle is 60%.
6. Future research may be done to determine the overcut and roughness of the machined region.
7. In future the machining characteristics can be optimized with advanced machine learning and optimization methods.

ABSTRACT

This paper introduces an improvement on zero- mean fractal color image compression techniques, using the YPbPr color space. The twocolor images (Lena and Parrot) were used to test the best PSNR, CR, ET, by fractal image coding by Zero-Mean method. In Lena image the calculated results were found to be (PSNR=30.99), (CR=10.52), (ET=63.68), while in Parrot image is (PSNR=29.59), (CR=10.52), (ET=47.44).

ABSTRACT

Visible light communication (VLC) has attracted people's attention due to its wide range of spectrum resources and good privacy in recent year. But research on visible light communication is mostly focused on LED materials, transfer protocol, transmission rates, etc. Lack of research that connect the visible light communications with existing communications methods. In this paper, we propose an Ethernet-visible data conversion system based on FPGA, including Ethernet interface logic, bit-width conversion logic, data buffer logic, and visible light communication transceiver logic. The proposed system achieves Ethernet and visible light access, and realizes 1000Mbps Ethernet data and 625Mbps visible light data conversion. Through buffer control, Ethernet data can be completely and reliably transmitted from high speed to low speed. By defining the structure of visible light communication frame and adding data self-recovery mechanism, data transmission has higher stability on the path of visible light. The feasibility of the system is proved by actual measurements.

INTRODUCTION

Wireless communication technology is widely used in our lives. As an emerging technology, visible light communication (VLC) is gradually entering the field of academics. Along with the popularization of solid-state lighting, LED (Light Emitting Diode) has been

applied to a large area. The Visible Light Communication uses LED as carrier, and uses electromagnetic wave in the visible light band as a carrier to modulate data information onto visible light, thereby achieving communication through it. Most of visible light communication researches focus on the point-to-point transmission in LOS (Line-of-sight) case [1]. Visible Light Communication doesn't occupy scarce radio spectrum and can be used without any license [2].

At present, research on visible light communication mostly focuses on material research [3], coding methods [4], modulation methods [5], and equalization methods [6]. Research focuses more on increasing transmission rates [7]. There are less researches on application. Some researches use

China (email: boylixj@foxmail.com). visible light as a supplement to RF technology [8]. Some researches on CDMA achieve multi-user access [9]. In the application scenario. Some researches use the visible light communication for audio transmission [10] and video display [11]. And underwater communication is performed with visible light [12]. These researches didn't take advantage of indoor applications of visible light. As an ideal indoor communication, visible light can be combined with common communication. The related research is currently lacking. Ethernet is them as tidily used communication technology. Most the rate of visible light communication applications on Ethernet are less than 100Mbps. Based on this, we propose an application design that combines visible light with Gigabit Ethernet. The research can solve the problem from Ethernet to visible light

The Ethernet-VLC data conversion system can achieve bidirectional adaptation of visible light signals and Ethernet signals, thereby accessing the purpose of connecting visible

light to Internet. The system uses fluorescent white LED. The modulation method of visible light communication is OOK (on-off keying). The visible light transceiver uses binary code. There is a gap large between the uplink and downlink of the visible light transmission rate at present [13]. The communication band width of fluorescent white LED is lower than Gigabit Ethernet. In system, the communication speed of LED is 625Mbps, which is lower than the speed of Gigabit Ethernet, they cannot be connected directly, and the conversion systems are required.

We propose a 1000Mbps Ethernet and 625Mbps visible light communication data conversion system. The system is based on FPGA to realize the transition of data flow. The system ensures the start, progress, and completion of data transmission applications. By defining the structure of visible light communication data frame and combining data stream self-recovery mechanism, the proposed method improves the stability of data transmission.

Modules of the System Design

The system is based on Xilinx FPGA Integrated GTP transceivers design. The proposed system block diagram is shown in Fig. 1. In the downlink, the 8-bit wide Gigabit Ethernet data is converted to 32-bit data through the Ethernet interface logic and the bit-width conversion logic. The frame is decelerated in the Ethernet-VLC buffer logic, the visible light communication transceiver logic framing and sent frame to optical path. In the uplink, the GTP transceiver receives the data from the optical path, performs de-frame processing through the transceiver logic, and sends the data to the VLC-Ethernet buffer logic to speed up to Gigabit. And

Fig. 1. Ethernet-VLC data conversion system block diagram.

Then the 8-bit data is re stored by the bit-width conversion logic. Finally, the frame is issued via the Ethernet interface.

Ethernet Interface Logic

The Ethernet interface logic completes the establishment of the communication interface and the configuration of the PHY chip. The functional diagram of the module is shown in Fig. 2. This interface logic design based on RGMII consists of three parts, i.e., SMI (Serial Management Interface), RX, and TX. SMI logic configures the registers in the Ethernet PHY layer slave through the MDC and MDIO interfaces to implement reset and auto-negotiation functions. When the auto-negotiation successes, Ethernet interface logic will be enabled. RX logic receives the Ethernet data, removes the frame header, and sends data information to bit-width conversion module after performing the CRC (Cyclic Redundancy Check) [14]. TX logic receives data sent from bit width conversion logic for new framing transmission. The frame interval needs to meet the minimum frame interval of the Ethernet in the process of transmission. The minimum frame interval of Gigabit Ethernet is 96 ns, and one clock is configured for 8 ns. When the interval time satisfies 12 clocks, the time is to enable signal. And the previous logic starts to send the package, otherwise the signal will be set low.

Bit-width Conversion Logic

Because the designs use GTP transceivers which only support 16-bit and 32-bit width data, we should perform width conversion. Considering that high bit width can reduce the frequency of the synchronous clock, this paper use 32-bit width. The bit width conversion logic is based on pseudo-dual-port RAM (Random Access Memory). The downlink writing bit-width is 8, the readout bit-width is 32, the uplink writing bit-width is 32, and the read out bit-width is 8. The uplink and downlink writing and readout operations are similar. Here we take an 8-bit to 32-bit module as an example.

In order to facilitate reading and writing, three address pointers are defined. The pointer WP (write pointer), write data with 8-bit width to RAM in ascending order of address. When writing the last byte of data frame, the first write address of the next frame is determined according to the length of the data frame. When the frame length is a multiple of 4, WP increases normally. When the frame length is not a multiple of 4, WP got the next address that is a multiple of 4. The pointer RP (read pointer), read 4 bytes of data from high to low at a time. The pointer VP (valid pointer), will be determined if the received data frame check value is correct. If the frame writing into buffer is correctly verified, VP will go to the current

position of WP. If the frame writing into buffer is incorrectly verified, WP will be returned to the current VP position.

The maximum byte-length of the Ethernet frame is 1518 and the minimum byte-length is 64. In order to satisfy the requirement of storing one frame of data, the capacity of the RAM is at least 2048 bytes (16384 bits). So the RAM capacity is 16Kb. In order to avoid the conflict when the address is read and written at the same time, the WP will be turned on after the full frame is written completely. However, when the previous frame is reading, the next frame is written completely, e.g. when after the frame A of length 1518 bytes is written, a frame B of length 64 bytes is written. The frame B is written during the reading of the frame A. But at this time, there is no logic to lay in the length information of frame B. Therefore, a FIFO (First Input First Output) storing length information is added to cooperate with the RAM to perform bit-width conversion. Considering that the capacity of the RAM is 2048 bytes, the FIFO bit-width is 11 and the bit-depth of the FIFO is 32 (2048 bytes/64 bytes).

Taking one frame as an example. The frame is written to the RAM according to the writing-enable signal. And then frame checked by CRC. If the result is correct, the signal will be pulled up raised one clock. The length information will be stored into the FIFO and VP go to WP. If the result is error, the writing-enable signal does not pull up, and then WP will go to VP. The timing diagram for the writing operation is shown in Fig. 3.

Fig.3.8 bit to 32bit module write operation timing diagram.

The RAM_WE is the writing-enable signal of RAM. When the signal is enabled. The 8-bit data D [7:0] is written in to the RAM with the write address RAM_WADDR [10:0]. In this process, the length information I [10: 0] cached into the FIFO. The signal IE represents a frame is written.

Frame readout based on FIFO status. Detect the status of FIFO. If FIFO is not empty, there adding process of one frame is started and the length information of the current frame is read from the FIFO. There ding timing diagrams shown in Fig. 4.

Fig.4.8bit to 32 bit module read out operation timing diagram

Buffer Logic

The buffer logic is the core of the system. The buffer in the uplink is responsible for slowing down the high-speed Ethernet data frames to the low-speed visible-light clock domain. In the downlink, the frame received from the visible light communication carried to the Ethernet clock domain. There by the logic implements two-way communication. The FIFO feature is suitable for buffers, which can reduce the complexity of the design [15]. The uplink and downlink buffers are composed of two asynchronous FIFOs, namely, the DFIFO (Data FIFO) that stores the data frame and the IFIFO (Information FIFO) that stores the frame length information. High-speed data synchronization to low-speed clock is a design difficulty.

The data transmission process complies with the Ethernet TCP/IP protocol. And there is a timeout retransmission rule. After the transmitter sends out one frame, if the acknowledgment information fed back by the receiver is not received within a certain period of time, the transmitter will resend the data until the feedback is received. Because data is transmitted from high speed to low speed and the buffer will be full, discard of data frames in evitable. But according to this rule, the receiver can receive the complete information correctly through the read-write control. The speed-down buffer is implemented based on this rule.

Depth calculation is very important to pass the data between different clock domains [16]. In downlink the deeper FIFO depth is better to use in speed-down buffer. Considering the device performance, the DFIFO bit-depth used in this paper is 8192 and the bit-width is 32.

To better control the buffer capacity, the threshold is set in the buffer. The amount of DFIFO (dfifo_data_count) is maintained between upper threshold and lower threshold. The longest frame has a byte-length of 1518, and a bit-depth of 190 in buffer. The shortest frame has a byte-length of 64, and a bit-depth of 190 in buffer. Considering the situation of continuously writing the longest frame, the upper threshold should ensure that the buffer is not full. The upper threshold is set to 7811 ($8191 - 190 \times 2$). The lower threshold keeps FIFO at half full state, and is set to 3715 ($4095 - 190 \times 2$). In uplink, the data pass through the buffer from low speed to high speed. There is no data congestion. When the back-to-back transmission is satisfied, two 1518-byte frames are continuously received. Since the FIFO depth is $2n$, it takes 4096 bytes and the bit-width is 32, so the bit-depth is 1024. The speed-up buffer IFIFO may approach the full state due to a large number of 64-byte frames are written. To avoid the IFIFO being full, upper threshold is set to 495 ($511 - 8 \times 2$), and the lower threshold is set to 8.

The writing process flowchart is shown in Fig.5. When the dfifo_data_count surpass the upper threshold, the writing-enable signal is turned off to stop writing. At this time, the buffer is only readout enabled. When the dfifo_data_count falls to the lower threshold, the writing-enable signal is enabled to continue writing data.

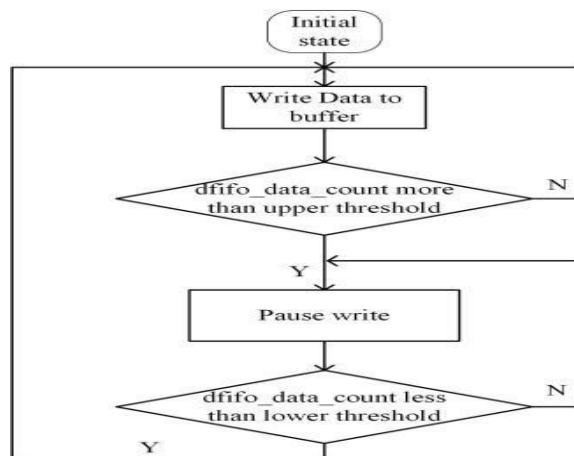

Fig.5. Buffer write control flow chart

The data read out process is shown in Fig.6. When the data in the IFIFO is not empty, the length information will be read, and the data frame will be read according to data length. If IFIFO is empty and DFIFO is non-empty, it indicates that data fragments exist in DFIFO. Currently, stop writing to Clear FIFO, and rely on this fragment cleaning mechanism to ensure the integrity of data transmission.

Visible Light Communication Transceiver Logic

The visible light communication transceiver logic assembles the data information into an VLC frame and sends it to the visible light channel via FPGA integrated GTP transceiver. The data clock recovery is integrated inside the GTP transceiver receiver. The data frame structure used in this paper is shown in Fig. 7. The data frame is based on 8B/10B coding technology. High-speed data transmission or data bus often uses 8B/10B protocol [17]. The visible light communication uses OOK modulation. The 8B/10B coding has a level-balancing feature that ensures that the LED does not flicker. The 8B/10B encoded data is serialized and decentralized via GTP transceiver. The frame includes a frame synchronization code, a frame start delimiter, a frame load, and a frame check. After the bit-width conversion, the frame bit-width is 32, that is 4 bytes of data are reprocessed under the same clock edge. For each frame, a frame synchronization code (0xff0000bc) is sent, which marks the arrival of a frame. Frame start delimiter (0xffxxxxfb) contains the length information of the frame (xxxx is the length information), and the length range is from 0 to 65535. Then the frame load is sent, that is, the encapsulated frame carries the data information. A frame check is added after the data part, which is used by the receiver to check, filter, and remove the data frames that have errors during transmission. The frame check uses CRC32. The calculation starts from the frame start code and stops at the end of the data part. There is a frame interval between data frames, where 0xbc is sent, corresponding to K28D5 of 8B10B. When the transmission

is idle, the transmitter will continuously send K28D5, which provides the receiver with the function of calibration.

Fig.7.Visible light communication frame structure.

The overall change process of the frame in the system is shown in the Fig. 8. The optical path can be easily affected by external interference which results in transmission interrupting. When the optical path is cut off, the receiver will detect a data error. But the

transmitter still sent the data, so the data transmission is maintained. At this time, if the optical path is turned on again, the receiver may receive the frame from the middle position, and the communication maybe break. In this case, a recovery mechanism is added to the transceiver logic. The receiver must check each frame to be received by the transceiver, and mark the wrong frame. When transmitting to the subsequent logic, the frame will be masked. Normal data transmission is resumed when reconnected.

SIMULATION AND EXPERIMENT RESULT

First, the feasibility of the system design is verified through simulation. In the simulation, the transmitter and the receiver of the optical path are connected. Fig. 9 and Fig. 10 are the simulation diagrams of the Ethernet side transmitter and receiver. It can be seen that the data is looped back and the result is correct.

Fig.9.The simulation diagrams of transmitter.

Fig.10.The simulation diagrams of receiver.

In the system experiment, the VLC side interface is connected to the oscilloscope, and the other side is connected to the Ethernet. The wave form can be observed by the oscilloscope, as shown in Fig.11.It is verified that the system reaches the rate of 625Mbps

Fig.11.VLC interface wave form diagram.

In the functional experiment, since the network cannot reach the full-speed Gigabit network in the general environment, a Gigabit Ethernet packet generator is used for the experiment. The packet generator can send data frames with a byte length of 64 to 1518 at full speed. The test environment diagram is shown in Fig. 12. The packet generator sends data to System1. After the data is converted, it is sent to the System 2byVLC. After System 2 receives the data, it returns data back to Ethernet and sends it to PC. PC uses the traffic monitoring software Ner Per Sec to detect the network speed. The network speed is shown in Fig. 13. The transmission rate is close to 500Mbps. Because the system uses 8B/10B encoding and decoding, the ratio between the data rate on the optical path after encoding and the data rate on Ethernet before encoding should be 5: 4. The 625 Mbps rate on optical path corresponds to the 500Mbps Ethernet rate. After the optical path is cut and reconnected, the system has restored the data connection, as shown in Fig. 14.

CONCLUSION

In this paper, we propose a design of an Ethernet-VLC data conversion system, which can realize the conversion between Gigabit network and 625Mbps optical data. We define the structure of the system and the functions of each module. Through simulation and experiments, we proved the feasibility of the system. And in order to improve the stability of the system, we defined the data frame structure and added recovery system at the receiver. Next, further research will be conducted in the areas of system buffer control and multi-user.

ABSTRACT

As the world faces increasing challenges from climate change, resource scarcity, and socio-economic disruptions, the need for adaptive technologies to support sustainable growth becomes paramount. Artificial Intelligence (AI) presents a powerful toolset for addressing these challenges by enabling adaptive systems that can learn from and respond to changing environments. This paper explores the role of AI in building resilience for sustainable growth, focusing on its applications in various sectors such as agriculture, healthcare, and infrastructure. We discuss how AI-powered adaptation can help in mitigating risks, optimizing resource allocation, and fostering innovation. Case studies and examples from around the world demonstrate the potential impact of AI in enhancing adaptive capacity and driving sustainable development. Finally, we discuss the challenges and opportunities in implementing AI-powered adaptation strategies and suggest future research directions in this field.

INTRODUCTION

Sustainable growth is a fundamental concept in the context of global development, emphasizing the need to balance economic progress with environmental protection and social equity. The idea, as articulated by the World Commission on Environment and Development in 1987, is to meet the needs of the present without compromising the ability of future generations to meet their own needs. This concept recognizes that our actions today have long-term consequences and that development must be pursued in a way that ensures the well-being of both current and future generations.

Achieving sustainable growth requires a proactive approach to addressing the challenges posed by climate change, resource depletion, and social inequalities. It requires us to adapt to changing environmental, social, and economic conditions while ensuring the efficient use of resources and minimizing negative impacts on the environment. This is where artificial intelligence (AI) can play a crucial role.

AI has emerged as a powerful tool for building resilience and promoting sustainable growth. By enabling adaptive systems that can learn from and respond to changing environments, AI has the potential to revolutionize the way we address complex challenges. In the context of sustainable growth, AI can help us develop more efficient and effective strategies for managing resources, mitigating risks, and fostering innovation.

This paper explores the role of AI in building resilience for sustainable growth. It will examine how AI-powered adaptation can help us address key challenges in various sectors, including agriculture, healthcare, and infrastructure. By highlighting the potential of AI to drive sustainable development, this paper aims to inspire further research and innovation in this exciting field.

AI-POWERED ADAPTATION IN AGRICULTURE

Agriculture is a cornerstone of human civilization, providing food, fiber, and fuel for populations around the world. However, agriculture is also one of the most vulnerable sectors to climate change, with changing weather patterns and extreme events posing significant challenges to food security. In this context, the integration of artificial intelligence (AI) into agricultural practices has the potential to revolutionize the way we approach farming and address these challenges.

One of the key advantages of AI in agriculture is its ability to process large amounts of data and provide real-time insights. AI-powered adaptation strategies can help farmers optimize crop yields, reduce water usage, and mitigate the impact of pests and diseases. For example, AI can analyze weather data and soil conditions to provide personalized recommendations to farmers on when to plant, irrigate, and harvest their crops. By incorporating AI into their decision-making processes, farmers can make more informed choices that can lead to higher yields and reduced environmental impact.

One of the areas where AI is making significant strides in agriculture is in precision farming. Precision farming involves using technology to tailor farming practices to individual fields or even individual plants. AI can analyze data from sensors, drones, and satellites to create detailed maps of fields, allowing farmers to apply fertilizers and pesticides more precisely. This not only reduces the amount of inputs needed but also minimizes environmental impact.

AI can also help farmers manage water more effectively. By analyzing weather patterns and soil moisture levels, AI can provide recommendations on when and how much to irrigate. This can help farmers reduce water waste and improve crop yields.

In addition to optimizing production, AI can also help farmers manage pests and diseases. By analyzing data on pest and disease outbreaks, AI can provide early warning signs and recommend appropriate action. This can help farmers reduce the need for chemical pesticides, leading to healthier crops and a more sustainable farming system.

Overall, AI-powered adaptation has the potential to revolutionize agriculture and help farmers adapt to a changing climate. By providing real-time insights and personalized recommendations, AI can help farmers optimize production, reduce waste, and mitigate environmental impact. As the technology continues to evolve, its potential to transform agriculture for the better is immense.

AI APPLICATIONS IN HEALTHCARE FOR SUSTAINABLE DEVELOPMENT

Healthcare systems worldwide are facing unprecedented challenges, including an aging population, the rising prevalence of chronic diseases, and limited resources. In this context, the integration of artificial intelligence (AI) into healthcare practices has the potential to transform the way we deliver care and improve patient outcomes. AI-powered solutions can enhance diagnosis accuracy, optimize treatment plans, and ultimately contribute to more sustainable healthcare systems.

One of the key advantages of AI in healthcare is its ability to process and analyze vast amounts of medical data quickly and accurately. This can be particularly useful in medical imaging, where AI algorithms can analyze images such as X-rays, MRIs, and CT scans to detect early signs of diseases such as cancer. By providing more accurate and timely

diagnoses, AI can help healthcare providers initiate treatment sooner, leading to better patient outcomes.

AI can also help optimize treatment plans by analyzing patient data and identifying the most effective interventions. For example, AI algorithms can analyze a patient's genetic information to predict how they are likely to respond to a particular treatment. This can help healthcare providers tailor treatment plans to individual patients, leading to better outcomes and reduced healthcare costs.

Another area where AI is making significant strides in healthcare is in the field of personalized medicine. By analyzing a patient's medical history, genetic makeup, and lifestyle factors, AI can help healthcare providers develop personalized treatment plans that are more effective and have fewer side effects. This not only improves patient outcomes but also reduces the need for trial-and-error approaches to treatment, leading to more sustainable use of healthcare resources.

In addition to improving diagnosis and treatment, AI can also help healthcare systems operate more efficiently. For example, AI-powered solutions can help hospitals and healthcare facilities optimize staff schedules, manage inventory more effectively, and reduce administrative burdens. By streamlining operations, AI can help healthcare systems reduce costs and improve overall sustainability.

Overall, AI has the potential to revolutionize healthcare and contribute to more sustainable healthcare systems. By improving diagnosis accuracy, optimizing treatment plans, and enhancing operational efficiency, AI can help healthcare providers deliver higher quality care to more patients while managing limited resources more effectively. As the technology continues to evolve, its impact on healthcare is expected to grow, leading to a more sustainable and resilient healthcare system for future generations.

AI-DRIVEN INFRASTRUCTURE DEVELOPMENT FOR SUSTAINABLE CITIES

Rapid urbanization is a global phenomenon that is reshaping cities and putting immense strain on infrastructure systems. As cities grow, they face challenges such as increased energy consumption, traffic congestion, and pollution. These challenges not only impact the environment but also the quality of life for urban residents. In this context, the integration of artificial intelligence (AI) into infrastructure development has the potential to

revolutionize the way cities are designed and managed, leading to more efficient, resilient, and sustainable urban environments.

One of the key advantages of AI in infrastructure development is its ability to process and analyze large amounts of data in real-time. This can be particularly useful in optimizing traffic flow in cities. AI algorithms can analyze data from traffic cameras, sensors, and GPS devices to predict traffic patterns and optimize signal timings. By reducing congestion and improving traffic flow, AI can help reduce emissions and improve air quality in cities.

AI can also be used to reduce energy consumption in buildings. By analyzing data on building usage, occupancy patterns, and energy usage, AI can identify opportunities for energy savings and recommend energy-efficient solutions. For example, AI can optimize heating, ventilation, and air conditioning (HVAC) systems to reduce energy waste while maintaining comfortable indoor temperatures.

Another area where AI is making a significant impact is in waste management. AI-powered solutions can analyze data on waste generation, collection routes, and landfill capacity to optimize waste collection and disposal processes. By reducing the amount of waste sent to landfills and increasing recycling rates, AI can help cities reduce their environmental footprint and move towards a more circular economy.

In addition to these examples, AI can also be used in other areas of infrastructure development, such as water management, public safety, and disaster response. By using AI technologies, cities can design infrastructure systems that are more efficient, resilient, and sustainable, ultimately leading to a better quality of life for urban residents. Despite the immense potential of AI-powered adaptation, there are several challenges that need to be addressed to maximize its benefits and minimize its risks. One of the key challenges is data privacy and security. AI systems rely on large amounts of data to learn and make decisions, raising concerns about how this data is collected, stored, and used. Ensuring that AI systems comply with privacy regulations and protect sensitive data is crucial to maintaining trust and confidence in these technologies.

Ethical considerations are another important challenge in the development and deployment of AI-powered adaptation strategies. As AI becomes more integrated into our daily lives, questions arise about the ethical implications of AI decision-making. For example, who is responsible if an AI system makes a decision that harms someone? How

can we ensure that AI systems are fair and unbiased? Addressing these ethical challenges requires careful consideration and proactive measures to ensure that AI is used in a responsible and ethical manner.

The digital divide is another challenge that needs to be addressed in the context of AI-powered adaptation. Access to AI technologies and the skills needed to use them are not evenly distributed, leading to disparities in who benefits from these technologies. Bridging the digital divide requires efforts to ensure that everyone has access to AI technologies and the opportunity to develop the skills needed to use them effectively.

Despite these challenges, there are also significant opportunities associated with AI-powered adaptation. One of the key opportunities is the potential for further research and development of AI algorithms. As AI technologies continue to evolve, there is an opportunity to develop more advanced and sophisticated algorithms that can address complex challenges in new and innovative ways.

Another opportunity lies in the integration of AI into existing systems and processes. By integrating AI into existing infrastructure, organizations can improve efficiency, reduce costs, and enhance decision-making. For example, AI can be used to optimize energy usage in buildings, improve traffic flow in cities, and enhance healthcare delivery.

In conclusion, while there are challenges associated with AI-powered adaptation, there are also significant opportunities for leveraging AI to address complex challenges and build a more sustainable future. By addressing these challenges and seizing these opportunities, we can harness the power of AI to revolutionize the way we adapt to and mitigate the impacts of climate change.

Conclusion

AI-powered adaptation presents a promising path towards building resilience and ensuring sustainable growth in a rapidly changing world. By leveraging the power of AI, we can develop innovative solutions to address complex and dynamic challenges such as climate change, resource depletion, and urbanization. AI has the potential to revolutionize the way we approach sustainability, offering new ways to optimize resource use, improve decision-making, and enhance the resilience of our systems.

However, realizing the full potential of AI-powered adaptation requires addressing several key challenges. These include ensuring data privacy and security, addressing ethical considerations, and bridging the digital divide. It is essential to develop governance frameworks and ethical guidelines to guide the development and deployment of AI technologies in a responsible and equitable manner.

Despite these challenges, the opportunities presented by AI-powered adaptation are immense. Further research and development of AI algorithms can lead to more advanced and effective solutions. Integrating AI into existing systems and processes can improve efficiency and decision-making across a wide range of sectors, from agriculture to healthcare to infrastructure development.

In conclusion, by addressing the challenges and seizing the opportunities presented by AI, we can create a more sustainable future for generations to come. By harnessing the power of AI-powered adaptation, we can build resilience, foster innovation, and ensure that our planet remains a livable place for all.

ABSTRACT

Wireless Underground Sensor Networks (WUSNs) that collect geospatial in situ sensor data are a backbone of internet-of-things (IoT) applications for agriculture and terrestrial ecology. In this paper, we first show how WUSNs can operate reliably under field conditions year- round and at the same time be used for determining and mapping soil conditions from the buried sensor nodes. We demonstrate the design and deployment of a 24-node WUSN installed at an agricultural field site that covers an area with a 530 m radius. The WUSN has continuously operated since September 2019, enabling real-time monitoring of soil volumetric water content (VWC), soil temperature (ST), and soil electrical conductivity. Secondly, we present data collected over a nine-month period across three seasons. We evaluate the performance of a deep learning algorithm in predicting soil VWC using various combinations of the received signal strength (RSSI) from each buried wireless node, above-ground pathloss, the distance between wireless node and receive antenna (D), ST, air temperature (AT), relative humidity (RH), and precipitation as input parameters to the model. The AT, RH, and precipitation were obtained from a nearby weather station. We find that a model with RSSI, D, AT, ST, and RH as inputs was able to predict soil VWC with an R^2 of 0.82 for test datasets, with a Root Mean Square Error of ± 0.012 (m^3/m^3). A combination of deep learning and other easily available soil and climatic parameters can be a viable candidate for replacing expensive soil VWC sensors in WUSNs.

FIRST-LEVEL HEADING: THE LINE BREAK WAS FORCED

This sample document demonstrates proper use of REVTEX 4.1 (and LATEX 2 ϵ) in manuscripts prepared for submission to AIP conference proceedings. Further information can be found in the documentation included in the distribution or available at <http://authors.aip.org> and in the documentation for REVTEX 4.1 itself. When commands are referred to in this example file, they are always shown with their required arguments, using normal TEX format. In this format, #1, #2, etc. stand for required author-supplied arguments to commands. For example, in `\section{#1}` the #1 stands for the title text of the author's section heading, and in `\title{#1}` the #1 stands for the title text of the paper. Line breaks in section headings at all levels can be introduced using `\\`. A blank input line tells TEX that the paragraph has ended.

Second-level heading: Formatting

In the present study we offer two contributions pursuant to our research goals noted in the introduction section. Firstly, we demonstrate the design and deployment of a WUSN and then examine the results of 9 months of continuous operation of a fully buried, non-intrusive WUSN at an agricultural field located at Fermi National Laboratory (Fermilab, Batavia, IL, USA). Through this demonstration, we show that a WUSN can operate under all-season, realistic field conditions. The wireless network is based on the increasingly used unlicensed ISM band, deployed around 900 MHz (in the USA) and made popular through low-power IoT wireless networks such as LoRa and Sigfox. The WUSN collects and maps soil VWC, electrical conductivity (EC), and soil temperature (ST) simultaneously, and the data can be visualized in near real-time through a web-based user interface. We discuss the performance of the WUSN through seasonal weather variations (fall, winter, and spring) and the impacts of climate, soil, and site characteristics affecting the sensor module transmissions.

Third-level heading Materials and Methods Sensor Node Development

Thoreau 2.0 is a modified version of an earlier system developed and operated at the University of Chicago campus described in Zhang et al. (2017) [11]. The wireless backbone of the Thoreau 2.0 system is a Sigfox 901.2 MHz low-power IoT wireless network, and the architecture contains three components: (1) the buried sensor nodes, (2) a base station, and

(3) a user interface (Figure 1).

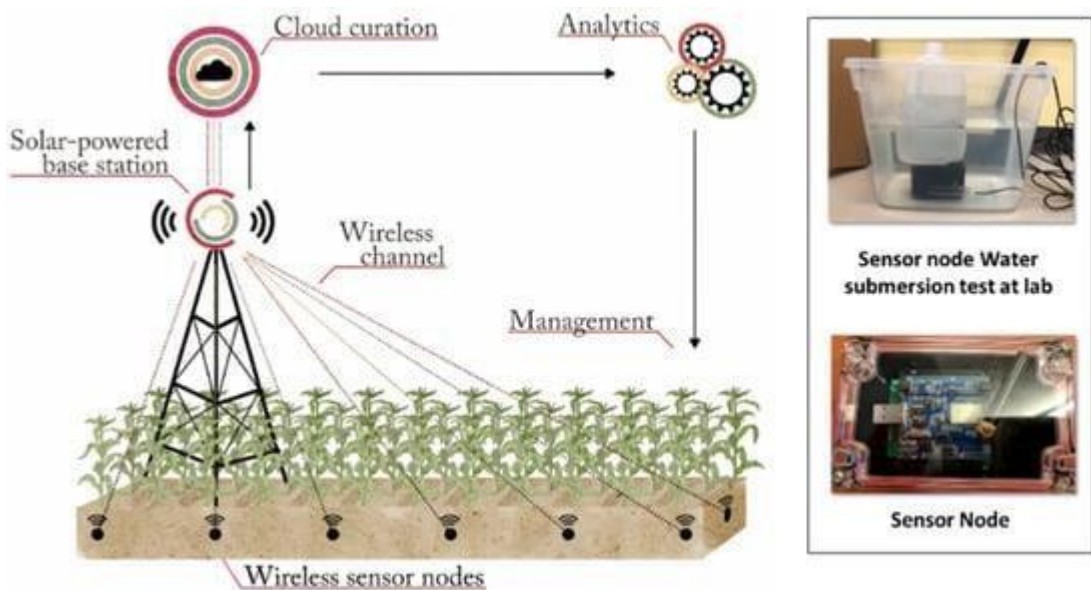

Figure 1. The wireless underground sensor network Thoreau 2.0 design. Inset shows sensor node and water submersion test conducted in the laboratory prior to field deployment.

Each sensor node consists of a sealed carbonate casing (16 cm × 8 cm × 8.5 cm) that contains the electronics, power source, and a transmitting antenna (Figure 1 inset shows the electronic components and antenna, while the power rack is housed beneath the electronics and cannot be seen in the picture). Each node is connected to an external sensor that simultaneously measures soil VWC, ST, and EC (TEROS12, Meter Environment, Pullman, Washington, DC, USA) in the vicinity of the box. The mechanical design of the sensor node box is critical. Building upon our experience from the first-generation WUSN (Thoreau 1.0, [11]), a hermetically sealed box was designed (Windy City Lab, Chicago, IL, USA) that could withstand extreme water and temperature fluctuations. We used O-rings around the lid to prevent leaks and silicone sealant to waterproof the encasing. A watertight, nylon cable gland was used for cable connection to the external sensor.

Multiline equations

Temporal Variation of Soil Properties

Measurements were collected over 289 days from 6 September 2019 through 20 June 2020. During this time, the WUSN operated continuously and produced 112,000 measurements after data curation and QA/QC. Descriptive statistics for soil VWC, EC, and ST, and weather variables AT, RH, and P averaged for the three seasons comprising the study time are shown in Table 1. 4 shows daily means for these variables and precipitation events.

Figure 4. Daily mean averages \pm standard deviation of soil volumetric water content (VWC)

(a), electrical conductivity (EC) (b), relative humidity (c), and soil and air temperature (d). Relative humidity and air temperature measurements were collected from the weather station shown in Figure 2. Blue bars are cumulative daily precipitation events. Shadows indicates the \pm standard deviation of the mean for VWC, EC, and RH.

Table 1. Season descriptive parameter statistics.

The overall high average soil EC values of the field site indicate good soil fertility. The site is composed of silt loam and silty clay loam soils that are prime farmland soils. Nevertheless, the soils have a tendency of being too wet, potentially creating nutrient build up, as indicated by high maximum soil EC and VWC, particularly in the spring, as shown in Table 1. As expected, soil VWC increases after each precipitation event (Figure 3a). A positive correlation of soil VWC with EC was observed throughout the study time ($R = 0.47$; Pearson correlation analysis, MATLAB R2020b). Analyzing the data by season, the correlation coefficients of soil VWC with EC are 0.54, 0.45, and 0.29 in fall, spring, and winter, respectively (Pearson correlation analysis, MATLAB R2020b). This correlation is not surprising, as it is known that the more water there is in the soil the more cations are in

solution and the soils' capacity to conduct electricity increases, resulting in higher EC values. Weather variations in RH, ST, and AT occurred throughout the study time, with cold winter and warmer spring temperatures, and frequent fluctuations in air temperature and relative humidity typical of continental climates (Figure 3c,d).

System Performance

Electromagnetic wave transmissions can be attenuated by several factors, including distance between a sensor node and the base station [2,10]. Figure 4a,b show the percentage of data packets received by the base station from the sensors during the 9 months of the study. Results indicate that there is a substantial loss of data packets from the sensor nodes that are farthest away from the base station (Figure 4a). In addition, we found that the amount of data received is not equal across sensors installed the same distance from the base antenna. Analysis of the data packets received from each sensor superimposed onto a topographic map (Figure 4b,c) suggests that the percentage of data packets received is a

function of sensor node distance to the base station, terrain elevation, and the localized concentration of soil moisture. For instance, sensors B3S20, B2S8, B2S11, B2S12, B2S13, and B2S21; and B3S19, B3S17, and B2S6 are installed approximately equidistant to the base station, but they differ in the number of data packets received by the base station. Sensor B2S8 (green pins in Figure 4b) is in a floodplain, leading to fewer data packets received compared to the nearest sensors B2S11 and B3S20, while sensors B2S7, B2S12, and B2S13 (red pins in Figure 4b) only differ in their topographic position and elevation yet have different data packet percentages (Figure 4b).

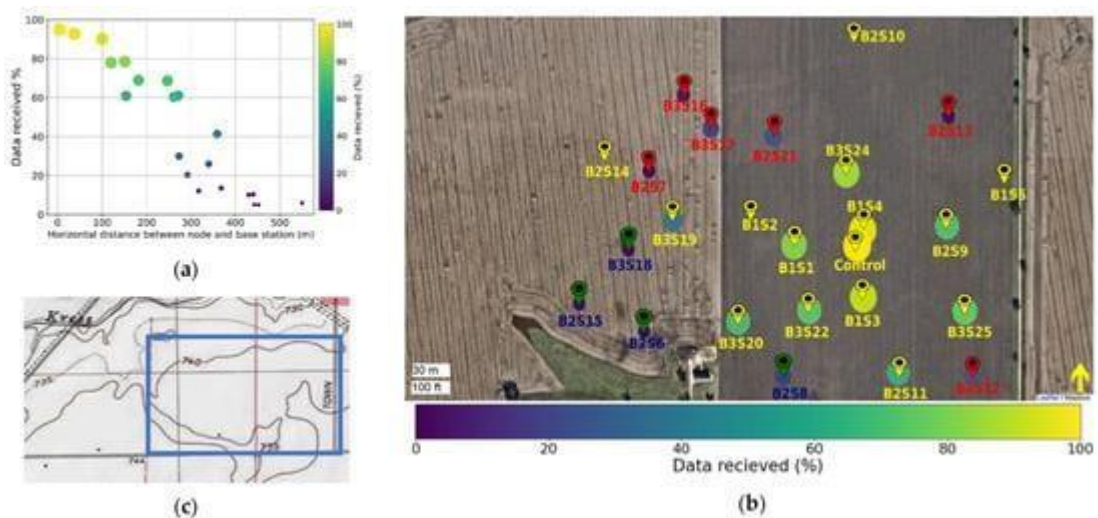

Figure 4. The average percentage of data packets received by the base station from the sensor nodes as a function of the horizontal distance from the base station (a) and from each sensor as they were located in the field (b). The size and color of the filled circles represents the percentage of data packets received. The flag indicates the base station location; yellow, red, and green pins represent sensors installed at 740 and 735 feet elevation and those installed in the flood plain zone of the study area, respectively (b). The soil topographic map (c) used to determine site elevation is retrieved from: <https://www.usgs.gov/search-map?search=3DEP> (accessed on 25 November 2020).

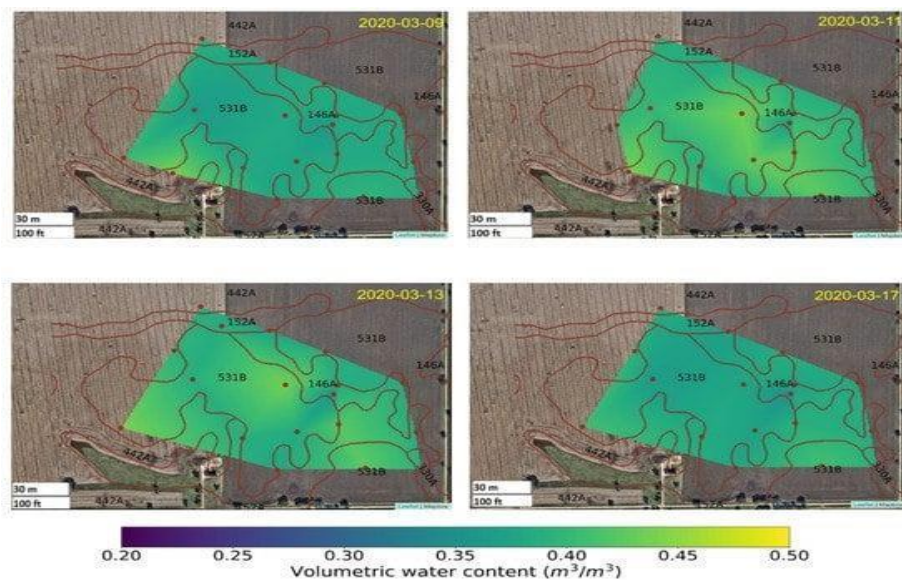

Figure 5. Volumetric water content (m^3/m^3) daily average intensity maps before and after

24.6 mm precipitation. Brown dots indicate sensor location and brown lines/numbers indicate soil types (brown lines and numbers denote USDA soil type assessment). Intensity maps were generated by linear interpolation between measured points.

Estimation of VWC from Received Signal Strength Indicator (RSSI)

The RSSI value received by the base station is generally lower than the original sensor node transmission. This signal attenuation is the result of the electromagnetic wave traveling through the soil medium and the free-space path in the air and intervening vegetation. Variations in soil moisture also affect RSSI values because the presence of moisture alters the soil's dielectric response to the propagation of the signal [10]. Figure 6 denotes RSSI values typically received by the base station, plotted against the soil VWC and the amount of precipitation at that time. As Figure 6 indicates, soil VWC rises following precipitation, sometimes reaching the upper detection limit of the sensor, and then decreases within a few hours to days due to soil water drainage and evaporation (when the soil is bare) or evapotranspiration (when plants are present). Correlation of soil VWC with RSSI is not present in winter, but it appears over the course of spring and early fall (Figure 6).

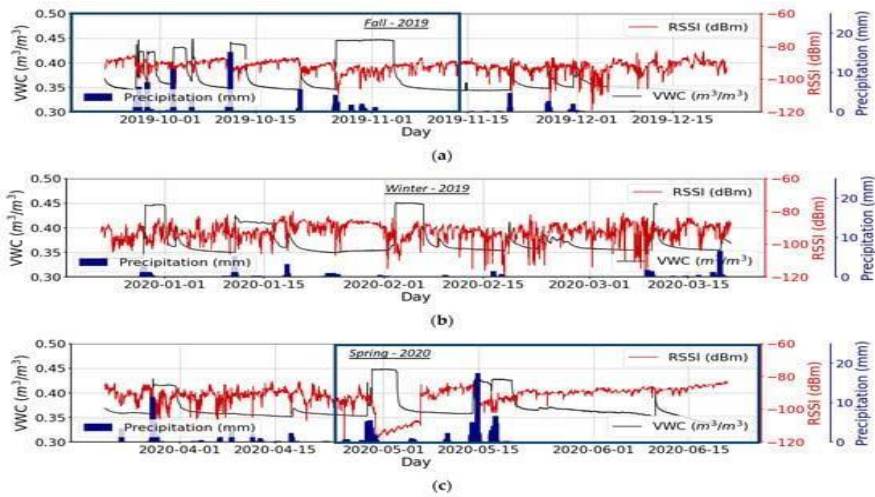

Figure 6. Measured RSSI (red line) and VWC (black line) by a sensor node buried 40 cm below the ground and located at 5 m to the base station during fall 2019 (a), winter 2019 (b), and spring 2020 (c) (from 6 September 2019 to 20 June 2020). Blue bars represent cumulative daily precipitation.

A correlation analysis using all data indicates a weak significant negative correlation ($R = -0.25$, $p\text{-value} = <0.005$) of soil VWC with RSSI. This analysis was conducted with a total of 92,000 datapoints, obtained after removal of soil VWC values that were above the maximum detection limit of the sensors, $0.45 \text{ m}^3/\text{m}^3$ (removal of 4000 datapoints), and of incomplete datasets due to temporary malfunction of the weather station that led to the removal of another 12,000 datapoints from our dataset. Because electromagnetic signal propagation is also impacted by other factors, such as terrain elevation and distance of the sensor node to the base station, as shown in Figure 4, and other factors identified in the literature, including climatic and weather factors [75,76], we investigated whether a nonlinear approach using standard machine learning algorithms could improve the prediction of soil VWC by taking into consideration RSSI and the various factors that might affect signal transmission from the sensors.

As noted earlier, we used an Artificial Neural Network with Multilayer Perceptron (ANN-MLP) algorithm (details in [58,77,78,79,80]) for constructing soil VWC predictive models. MATLAB R2020b was used for the neural network development, training, and simulations [81]. The total dataset was randomly classified into 70% for training (64,000 datapoints), 15% for validation (13,500 datapoints), and 15% for testing (13,500 datapoints).

Soil VWC in situ measurements (collected by the external soil sensor) were used as ground truth data and target parameters for the model. Available input parameters that could be used to train the model included WUSN site parameters (RSSI and hypotenuse distance (D) between the buried sensor node and base station antenna) and soil (ST) and weather parameters (P, AT, and RH). Weather parameters were averaged at 30 min intervals to harmonize all data to that time interval for the model.

WUSN/site parameters are those that can be obtained directly from the deployment of the WUSN in the field. Because the signal transmitted from a buried node first travels through the soil, the power (PT (in dB)) at the soil surface depends on the moisture content in the soil. After traveling through the air with a free space pathloss proportional to $20 \times \log(D)$, where D is the hypotenuse distance of the buried sensor to the antenna, the signal is received at the base station antenna with a certain RSSI. Hence, one can approximate PT as being proportional to the sum of $20 \times \log(D)$ and RSSI. The distance (D) appears as a separate parameter in addition to the $20 \times \log(D)$ factor in the estimate of PT in order to capture propagation effects, such as multipath, which are not accounted for in the free space pathloss. These site parameters along with the measured weather and soil variables were used as input parameters for evaluating the machine learning algorithm.

Trial and error was used to select the optimum number of hidden layers and number of neurons. Table A1 in Appendix A shows the performance matrix of different combinations of hidden layers and number of neurons. Ultimately, a five-layer feed-forward neural network including three hidden layers, one input layer, and one output layer, with each hidden layer containing 55 neurons, was selected based upon performance in VWC predictions. The Levenberg–Marquardt algorithm was used for network training. To avoid overtraining, we used an early stopping training method. Model performance was assessed by comparing the coefficient of determination (R^2), root mean square error (RMSE), and mean absolute error (MAE) of the estimated value of soil VWC to in situ, ground-truth measurements. All input and target parameters were normalized to a range between 0.2 to 0.8, as suggested by Cigizoglu (2003) [82]. Table 2 shows the performance of this model in training, validation, and te le 2. Results of ANN-MLP model with different input parameter combinations.

In contrast, running the model with only site input parameters, i.e., using only RSSI + 20 × log(D) and D as input parameters, substantially reduced the performance of the model, rendering unacceptable predictions (Table 2, two-parameter model). We determined that ST is an important variable in determining the model’s predictive ability, i.e., any model was substantially improved when ST was included as an input parameter (Table 2, three-, four-, and five-parameter models). Similarly, but to a lesser extent, the performance of the model could be further improved with the addition of AT and RH as input parameters (in addition to RSSI + 20 × log(D), D, and ST as inputs) leading to four- and five-parameter models (see Table 2). For example, Figure 7 shows measured and predicted soil VWC when using the ANN-MLP model with RSSI + 20 × log(D), D, ST, AT, and RH as input parameters. Including P in the model did not affect model performance (Table 2). Since P is infrequent, there were fewer inputs into the algorithm, which might have reduced its influence on model performance. Nevertheless, it is possible that the effect of P might already have been accounted for, indirectly, by RSSI and RH variations.

Figure 7. Measured and predicted soil volumetric water content (VWC) at training (a), validation (b), and testing (c) stages of the ANN-MLP model using input parameters: distance of the sensor node to the antenna (D), $RSSI + 20 \times \log(D)$, relative humidity (RH), and soil and atmospheric temperature. Model is highlighted in bold on Table 2 as the best-performing model.

While RSSI is expected to and has been previously shown to be affected by soil VWC due to changes in the soil's dielectric properties under limited testing conditions [10,36,38,69], our results summarized in Table 2 (and the seasonal examples highlighted in Figure 6) clearly show that RSSI alone is a poor consistent predictor of soil VWC, and we propose the use of this algorithm as an alternative method for estimating soil VWC with WUSNs. Indeed, dropping RH as an input parameter and using a four-parameter model also leads to good prediction of soil VWC ($R^2 = 0.82$). The approach described above, while obviating the need for an expensive VWC sensor at every node, does require other soil and weather data. However, many algorithms developed to predict ST from AT can render this approach feasible [83,84,85,86].

We compared the performance of the six-parameter ANN-MLP model with two other commonly used machine learning algorithms: Support Vector Regression (SVR) [87,88,89] and Extreme Learning Machines (ELMs) [90,91]. We used these algorithms to predict soil moisture in the same way as for our ANN-MLP model, and the implementation details of the two models are described in Appendix B. The performance statistics of the two models are presented in Table 3, showing the best results across a collection of SVR kernel functions and ELM activation functions. Grid searches for these two models yielded poorer results than the ANN-MLP model. The best SVR model was found with a radial basis function (RBF) kernel which resulted in $R^2 = 0.56$ and $RMSE = 0.053 \text{ m}^3/\text{m}^3$ for the testing stage; the best ELM model was found with a sigmoid activation function, which resulted in $R^2 = 0.48$ and $RMSE = 0.06 \text{ m}^3/\text{m}^3$ for the testing stage. The reason for these models' poor performance in comparison to the ANN-MLP model is unclear and beyond the scope of the current paper. We can conclude, however, that our deep learning approach surpasses the other surveyed methods even without a thorough grid search, and that the ANN-MLP model proves a useful tool in predicting geospatial VWC.

Table 3. Results of Support Vector Regression (SVR) and Extreme Learning Machines (ELMs) for training and testing stages.

We now make a few comments regarding our analysis. Firstly, note that we did not include the polarization and antenna gain for the sensor node transmitters as input parameters. Polarization and antenna gains cannot be controlled precisely, especially in a real-world field deployment such as described in this paper. With ML, if measurements from each sensor are adequately represented in the training set, these, as well as other hidden factors, such as differences in terrain, will be learned by the model during the training phase. In the experiment, 92,000 datapoints were collected from 23 sensor nodes over 9 months, ensuring that measurements from each sensor node were well-represented in the training data. Furthermore, in estimating soil moisture, the ML model utilizes the relative difference in RSSI between wet soil and dry soil from each sensor, and hence, the absolute effect of

polarization, antenna gain, and terrain do not need to be modeled accurately since these do not change with the level of moisture in the soil. Secondly, as noted in Section 3.2, some sites can have lower number of successful transmissions due to factors such as distance, topography, etc. To examine this effect, we tested the model with data from the sites that had >50% and <50% data packet transmission rates, and the difference in performance statistics during testing was not significant. However, this is a parameter that will likely need to be examined and tested in other site installations.

sting with various combinations of input parameters. The six-input parameter model, containing all site and climate input parameters, predicted soil VWC with very good accuracy and low RMSE and MAE.

Conclusions

In this paper, we present the successful design and deployment of Thoreau 2.0, a scalable, low-power WUSN for subterranean sensing. The WUSN has been operating continuously in an agricultural field since September 2019, and we present data collected

over 9 months (three seasons). High temporal and spatial resolutions were accomplished by measuring soil conditions at 30 min intervals and interpolating and mapping the sensor results over an approximated 530 m radius area. We showcase the ability of our WUSN to monitor and map real-time variations in soil VWC, ST, and EC. Our results show that such WUSNs can be reliably operated under “real-world” conditions and are scalable. Using the RSSI signal from the WUSN along with other inputs as proxies, we developed a deep learning model that can accurately predict and map an important parameter for soil ecology and agriculture: volumetric water content (or soil moisture). This enables soil moisture determination without the need for expensive sensors for direct VWC measurement.

ABSTRACT

Quantum computing represents a paradigm shift in computation, promising exponential speedup for certain computational tasks. In recent years, quantum algorithms and quantum machine learning have emerged as two exciting areas of research, leveraging the unique properties of quantum mechanics to address complex computational problems more efficiently than classical approaches. This paper overviews quantum algorithms and machine learning techniques, highlighting their theoretical foundations, practical implementations, and potential applications. We discuss key quantum algorithms such as Shor's algorithm, Grover's algorithm, and quantum simulation algorithms, exploring their advantages, limitations, and current research directions. Additionally, we delve into quantum machine learning approaches, including quantum-enhanced algorithms for classification, clustering, regression, and generative modeling, examining their implications for data processing and pattern recognition tasks. Through this comprehensive analysis, we aim to provide insights into the transformative potential of quantum computing for solving real-world computational challenges and driving innovation in data-driven fields.

Keywords

Quantum computing, Quantum algorithms, Quantum machine learning, Shor's algorithm, Grover's algorithm, Quantum simulation, Quantum neural networks, Quantum generative models.

INTRODUCTION

Quantum computing marks a revolutionary departure from classical computation, offering a paradigm shift in our approach to solving computationally intensive problems. Unlike classical computers that process information in binary bits, quantum computers leverage the principles of quantum mechanics to manipulate quantum bits or qubits. These qubits can exist in superpositions of states, enabling quantum computers to explore vast solution spaces simultaneously and potentially achieve exponential speedup for specific tasks.

The motivation for delving into quantum algorithms and quantum machine learning stems from the tantalizing prospects that quantum computing offers. Traditional computing architectures encounter limitations when confronted with certain complex computational problems, such as integer factorization or optimization tasks. Quantum algorithms, such as Shor's algorithm and Grover's algorithm, present solutions that exhibit exponential speedup over their classical counterparts, promising transformative implications for cryptography, optimization, and data processing.

Similarly, the convergence of quantum computing with machine learning heralds a new frontier in data analysis and pattern recognition. Quantum machine learning techniques harness the unique properties of quantum mechanics to enhance computational efficiency and enable novel approaches to solving machine learning tasks. By integrating classical and quantum computation, quantum machine learning models offer the potential to tackle previously intractable problems and unlock new insights across diverse domains.

The objectives of this paper are threefold. Firstly, we aim to provide an overview of quantum computing, elucidating its underlying principles, computational model, and potential advantages over classical computing. Secondly, we seek to explore the motivation behind studying quantum algorithms and quantum machine learning, highlighting the transformative impact these fields can have on various applications. Lastly, we endeavor to outline the scope and structure of the paper, which will delve into the theoretical foundations, practical implementations, and potential applications of quantum algorithms and quantum machine learning techniques. Through this comprehensive analysis, we aim to contribute to the burgeoning discourse on quantum computing and inspire further exploration and collaboration in this rapidly evolving field.

QUANTUM ALGORITHMS

Shor's algorithm, devised by mathematician Peter Shor in 1994, is a groundbreaking quantum algorithm that revolutionized the field of cryptography and number theory. The algorithm's primary objective is to efficiently factorize large integers, a task that poses a significant challenge for classical computers due to the exponential growth in computational complexity with increasing integer size.

Explanation of the Algorithm for Integer Factorization

At its core, Shor's algorithm exploits the principles of quantum computation to perform modular exponentiation and period finding efficiently. The set of rules includes numerous key steps:

Initialization

Begin by selecting a random integer a between 2 and $(N-1)$, where N is the number to be factorized.

Modular Exponentiation

For a given integer x , compute $f(x) = a^x \pmod N$ using modular exponentiation. This can be efficiently implemented classically or on a quantum computer using the quantum modular exponentiation algorithm.

Period Finding

The key insight of Shor's algorithm lies in finding the period r of the function $f(x)$. This can be achieved using quantum algorithms such as the Quantum Fourier Transform (QFT). Let r be the smallest positive integer such that $a^r \equiv 1 \pmod N$. Then, r is the period of $f(x)$.

Factor Extraction

Once the period r is determined, it can be used to factorize N . If r is even and $a^{r/2} \not\equiv -1 \pmod N$, then the factors of N can be obtained as $\gcd(a^{r/2} \pm 1, N)$.

Implications for Cryptography and Number Theory

Shor's algorithm's ability to efficiently factorize large integers has profound implications for cryptography, particularly for systems reliant on the hardness of integer factorization for security, such as RSA encryption. The security of RSA encryption relies on the assumption that factoring large integers into their prime factors is computationally infeasible. However, Shor's algorithm undermines this assumption by demonstrating the feasibility of factorization on a quantum computer, posing a significant threat to classical cryptographic systems.

Moreover, Shor's algorithm has broader implications for number theory, offering a new perspective on the computational complexity of fundamental mathematical problems. The algorithm's efficiency in factorizing integers highlights the disparity between classical and quantum computational capabilities, prompting further exploration of quantum algorithms for solving classical mathematical problems.

Current Developments and Challenges

While Shor's algorithm provides a theoretical framework for efficient integer factorization on a quantum computer, several challenges remain in its practical implementation. These include:

Qubit Coherence and Error Rates

Quantum algorithms are susceptible to errors due to decoherence and noise. Maintaining qubit coherence over long periods and reducing error rates are ongoing challenges in quantum computing.

Hardware Scalability

Shor's algorithm requires a large number of qubits to factorize large integers. Scaling up quantum hardware to support the necessary number of qubits while maintaining qubit coherence is a significant challenge.

Algorithmic Design

Optimizing the performance of Shor's algorithm requires careful algorithmic design and implementation. This includes optimizing the quantum circuit for modular exponentiation and period finding, as well as minimizing error rates and resource usage.

Despite these challenges, recent advancements in quantum hardware and error correction techniques have brought the practical implementation of Shor's algorithm closer to reality. Continued research in quantum computing hardware, algorithm design, and error correction will be critical for realizing the full potential of Shor's algorithm in practical applications.

Grover's Algorithm

Grover's algorithm, proposed by Lov Grover in 1996, is a quantum algorithm designed to perform an unstructured search over a database. Unlike classical search algorithms, which typically require examining each item in the database sequentially, Grover's algorithm offers a quadratic speedup, significantly reducing the search time.

Description of the Algorithm for Unstructured Search

At its core, Grover's algorithm employs quantum parallelism and amplitude amplification to accelerate the search process. The algorithm's key steps include:

Superposition

Start with a uniform superposition of all possible states representing the items in the database.

$$| \psi_0 \rangle = \frac{1}{\sqrt{N}} \sum_{i=0}^{N-1} | i \rangle$$

Oracle Query

Apply an oracle function that marks the desired solution(s) in the quantum state. The oracle function effectively acts as a black box, flipping the sign of the amplitude corresponding to the target solution(s).

$$U_f | x \rangle = (-1)^{f(x)} | x \rangle$$

Amplitude Amplification

Utilize amplitude amplification techniques, such as Grover iteration, to amplify the amplitudes of the marked solutions while suppressing the amplitudes of the unmarked

solutions. This step involves iteratively applying the oracle and inversion about the mean operations to concentrate the probability amplitudes on the target solution(s).

$$G = S_w \cdot U_f \cdot S_0 \cdot U_s$$

Where (S_w) is the inversion about the mean (or Grover diffusion operator), (U_f) is the oracle function, (S_0) is the inversion about the initial state, and (U_s) is the uniform superposition operator.

Measurement

Finally, measure the quantum state to obtain the solution(s) with high probability. The probability of measuring the desired solution(s) increases quadratically with the number of iterations performed.

The number of iterations required for Grover's algorithm to find the target item(s) with high probability is approximately $(O(\sqrt{N}))$, leading to a quadratic speedup over classical search algorithms.

Applications in Database Search and Optimization

Grover's set of rules has numerous packages in diverse computational tasks, inclusive of database search, optimization, and cryptographic attacks. In the context of database search, the algorithm enables efficient retrieval of information from unsorted databases, offering a quadratic speedup over classical search algorithms. This capability has implications for a wide range of applications, including data retrieval, pattern recognition, and optimization problems.

Moreover, Grover's algorithm can be applied to optimization problems, such as finding the minimum or maximum of a function, by encoding the problem as a search over a solution space. While Grover's algorithm does not offer an exponential speedup for optimization tasks, it can still provide a quadratic speedup over classical algorithms, leading to improved efficiency in finding optimal solutions.

Optimization Strategies and Quantum Oracle Implementation

Optimizing the performance of Grover's algorithm involves carefully selecting the number of iterations and optimizing the oracle implementation to minimize the overall computational complexity. The choice of oracle function significantly impacts the algorithm's efficiency, as it determines the accuracy and effectiveness of marking the target solution(s) in the quantum state.

Quantum oracle implementation strategies vary depending on the nature of the search problem and the available resources. In some cases, analytical or explicit construction of the oracle function may be feasible, while in others, black-box access to the problem's information may be required.

Researchers continue to explore novel techniques for designing efficient quantum oracles and optimizing Grover's algorithm for various applications.

In summary, Grover's algorithm offers a powerful tool for accelerating unstructured search and optimization tasks on quantum computers. By leveraging quantum parallelism and amplitude amplification, the algorithm enables efficient retrieval of information from unsorted databases and optimization of objective functions. Ongoing research focuses on optimizing the algorithm's performance and exploring its applications in diverse computational domains.

Quantum Simulation Algorithms

Quantum simulation algorithms play a crucial role in leveraging quantum computers to simulate quantum systems, offering insights into complex physical phenomena that are challenging to study using classical computational methods. These algorithms enable researchers to model the behavior of quantum systems with unprecedented accuracy and efficiency, paving the way for advances in materials science, chemistry, and physics.

Role of Quantum Computers in Simulating Quantum Systems

Role of Quantum Computers in Simulating Quantum Systems

Quantum computers excel at simulating quantum systems due to their inherent ability to manipulate quantum states and perform quantum operations. Unlike classical computers, which struggle to simulate large-scale quantum systems efficiently, quantum computers can

exploit quantum parallelism and entanglement to simulate complex quantum phenomena with exponential speedup.

Quantum simulation algorithms leverage these quantum properties to represent and evolve the quantum state of a simulated system, enabling researchers to study its dynamics, properties, and interactions. By accurately simulating quantum systems, researchers can explore novel materials, understand chemical reactions, and investigate fundamental physical phenomena with unprecedented precision.

Examples of Quantum Simulation Algorithms

Several quantum simulation algorithms have been proposed and developed to address specific classes of quantum systems and phenomena. These algorithms vary in complexity and applicability, depending on the nature of the simulated system and the desired level of accuracy. Some notable examples include:

Variational Quantum Eigensolver (VQE)

VQE is a hybrid quantum-classical algorithm used to approximate the ground state energy of a quantum system. By iteratively optimizing a parameterized quantum circuit and evaluating its energy, VQE can efficiently estimate the ground state energy, enabling researchers to study the properties of quantum systems and molecules.

Quantum Phase Estimation (QPE)

QPE is a quantum algorithm used to estimate the eigenvalues of a unitary operator, which encodes the energy levels of a quantum system. By applying QPE to the Hamiltonian operator of a quantum system, researchers can obtain accurate estimates of its energy spectrum, facilitating the study of its dynamics and properties.

Quantum Variational Simulation (QVS)

QVS is a quantum algorithm designed to simulate the time evolution of quantum systems by approximating the unitary time evolution operator using parameterized quantum circuits. By optimizing the parameters of the quantum circuit to minimize the error in

simulating the time evolution, QVS can efficiently simulate the dynamics of quantum systems and phenomena.

Potential Applications in Materials Science, Chemistry, and Physics

Quantum simulation algorithms hold immense promise for advancing research in materials science, chemistry, and physics, enabling researchers to explore new materials, understand chemical reactions, and investigate fundamental physical phenomena with unprecedented accuracy and efficiency. Some potential applications include:

Materials Discovery and Design

Quantum simulation algorithms can be used to predict the properties of novel materials, such as superconductors, catalysts, and semiconductors, accelerating the discovery and design of materials with desired properties for various applications.

Chemical Reaction Mechanisms

Quantum simulation algorithms can elucidate the mechanisms of chemical reactions, providing insights into reaction kinetics, reaction pathways, and reaction energetics. By accurately simulating chemical reactions, researchers can optimize reaction conditions and design more efficient chemical processes.

Quantum Many-Body Systems

Quantum simulation algorithms enable researchers to study the behavior of complex many-body systems, such as strongly correlated electron systems, quantum magnets, and quantum fluids. By accurately simulating the dynamics of these systems, researchers can explore emergent phenomena, phase transitions, and quantum criticality.

In summary, quantum simulation algorithms offer a powerful tool for simulating quantum systems with unprecedented accuracy and efficiency, enabling researchers to explore complex physical phenomena and advance scientific knowledge in materials science, chemistry, and physics. Ongoing research focuses on developing more efficient quantum simulation algorithms, improving their scalability and accuracy, and exploring their applications in diverse scientific domains.

QUANTUM MACHINE LEARNING

Quantum-Classical Hybrid Models

Quantum-classical hybrid models represent a fusion of classical machine learning techniques with quantum algorithms, leveraging the strengths of both paradigms to tackle complex computational problems efficiently. This integration harnesses the powerful computational capabilities of quantum computing while leveraging classical processing for tasks suited to conventional algorithms.

Integration of Quantum Algorithms with Classical Machine Learning Techniques

Hybrid quantum-classical models typically involve embedding quantum algorithms within classical machine learning frameworks. For instance, quantum algorithms, such as variational quantum eigensolvers (VQEs) or quantum approximate optimization algorithms (QAOAs), can be used as components within classical optimization or learning pipelines. In this approach, classical algorithms handle preprocessing, feature extraction, and post-processing, while quantum algorithms perform specific tasks, such as optimization or feature selection, within the overall learning process.

Advantages of Hybrid Quantum-Classical Approaches

The integration of quantum and classical techniques offers several advantages:

Enhanced Computational Power

By leveraging the strengths of quantum computing, hybrid models can tackle computationally intensive tasks more efficiently than purely classical approaches, particularly for optimization and sampling problems.

Flexibility and Scalability

Hybrid models provide a flexible framework for incorporating quantum algorithms into existing machine learning workflows, allowing for modular design and scalability to larger datasets or more complex problems.

Improved Performance

In many cases, hybrid quantum-classical models outperform purely classical algorithms, particularly for tasks where quantum algorithms offer a significant advantage, such as certain optimization problems or feature selection tasks.

Case Studies and Experimental Results

Several case studies and experimental results showcase the effectiveness of hybrid quantum-classical approaches:

Hybrid Quantum-Classical Optimization

Researchers have demonstrated the use of quantum optimization algorithms, such as QAOA, within classical optimization frameworks for solving combinatorial optimization problems, such as the traveling salesman problem or graph partitioning.

Quantum-Assisted Machine Learning

Hybrid models have been applied to various machine learning tasks, including classification, clustering, and regression. By incorporating quantum algorithms for feature selection or dimensionality reduction, researchers have achieved improved performance on benchmark datasets.

Chemistry and Materials Science

In fields like quantum chemistry and materials science, hybrid quantum-classical models have been used to simulate molecular structures, predict material properties, and optimize chemical reactions, demonstrating the potential for quantum-enhanced computational techniques in scientific research and discovery.

In conclusion, hybrid quantum-classical models represent a promising approach for leveraging the computational advantages of quantum computing within classical machine learning frameworks. By integrating quantum algorithms with classical techniques, these models offer enhanced computational power, flexibility, and performance across a wide range of applications.

Quantum Neural Networks

Quantum neural networks (QNNs) are a class of neural network architectures that leverage the principles of quantum mechanics to perform certain computational tasks more efficiently than classical neural networks. These models offer potential advantages for pattern recognition, data analysis, and optimization problems by harnessing the unique properties of quantum computation.

Overview of Quantum Neural Network Architectures

Quantum neural networks can be categorized into several architectures, including:

Quantum Perceptrons

Analogous to classical perceptrons, quantum perceptrons are the building blocks of quantum neural networks. They consist of quantum gates acting on qubits to perform simple computational tasks, such as classification or regression.

Quantum Convolutional Neural Networks (QCNNs)

QCNNs extend classical convolutional neural networks (CNNs) to operate on quantum data representations. They use quantum gates to perform convolutional operations and pooling operations on quantum feature maps, enabling efficient pattern recognition and image classification tasks.

Quantum Recurrent Neural Networks (QRNNs)

QRNNs leverage quantum gates to implement recurrent connections and memory units, enabling them to process sequential data and time-series information efficiently. They are well-suited for tasks such as natural language processing, speech recognition, and time-series prediction.

Training Algorithms and Optimization Techniques

Training quantum neural networks involves optimizing the parameters of the quantum circuits or gates to minimize a loss function, similar to classical neural networks. However,

due to the inherent complexity of quantum computation, training QNNs requires specialized optimization techniques and algorithms. Some common approaches include:

Variational Quantum Circuit Optimization

Variational quantum circuits, parameterized quantum circuits whose parameters are optimized to minimize a cost function, are commonly used to train QNNs. Quantum-classical hybrid optimization algorithms, such as the quantum approximate optimization algorithm (QAOA), can be used to optimize the parameters of variational quantum circuits efficiently. Quantum gradient descent algorithms adapt classical gradient descent techniques to the quantum domain, enabling the optimization of quantum neural network parameters using gradient-based methods. These algorithms leverage the quantum gradient information to update the parameters of the quantum circuits iteratively.

Quantum Simulated Annealing

Inspired by classical simulated annealing algorithms, quantum simulated annealing methods explore the energy landscape of quantum neural networks to find optimal parameter configurations. By gradually cooling the system to its ground state, these algorithms can effectively optimize the parameters of quantum circuits.

Applications in Pattern Recognition and Data Analysis

Quantum neural networks have applications in various domains, including:

Pattern Recognition

QNNs excel at pattern recognition tasks, such as image classification, object detection, and pattern matching. Their ability to process quantum data representations and exploit quantum parallelism makes them well-suited for recognizing complex patterns in high-dimensional data.

Data Analysis

Quantum neural networks can analyze and process large datasets efficiently, extracting meaningful insights and patterns from noisy or incomplete data. They have applications in data clustering, dimensionality reduction, and anomaly detection, enabling researchers to uncover hidden structures and relationships within complex datasets.

In summary, quantum neural networks offer a powerful framework for performing pattern recognition, data analysis, and optimization tasks using quantum computation techniques. By leveraging the principles of quantum mechanics, these models provide potential advantages

Quantum generative models represent a class of generative modeling techniques that leverage quantum computing principles to generate data distributions efficiently. Among these models, quantum generative adversarial networks (QGANs) have garnered significant attention for their potential applications in synthetic data generation, simulation, and quantum-enhanced machine learning tasks.

Introduction to Quantum Generative Adversarial Networks (QGANs)

QGANs extend the framework of classical generative adversarial networks (GANs) to the quantum domain, leveraging quantum circuits to generate data distributions. Similar to classical GANs, QGANs consist of two neural networks: a generator and a discriminator. The generator generates samples from a target data distribution, while the discriminator distinguishes between real and generated samples. By training the generator to fool the discriminator, QGANs learn to generate samples that closely resemble the target distribution.

Generation of Quantum Data Distributions

In QGANs, the generator and discriminator are implemented as parameterized quantum circuits, whose parameters are optimized to generate and discriminate quantum data samples, respectively. The generator circuit takes as input a set of random quantum states and transforms them into samples from the target distribution, while the discriminator circuit distinguishes between real and generated samples based on certain discriminative features.

During training, the generator and discriminator circuits are trained iteratively using a quantumclassical optimization algorithm, such as quantum gradient descent or variational quantum eigensolver (VQE), to minimize a characteristic that captures the discrepancy between the generated and actual facts distributions. By optimizing the parameters of the generator circuit to generate samples that fool the discriminator, QGANs learn to generate samples that closely resemble the target data distribution.

Potential Applications in Synthetic Data Generation and Simulation

QGANs have several potential applications in synthetic data generation, simulation, and quantumenhanced machine learning tasks:

Data Augmentation

QGANs can generate synthetic data samples to augment existing datasets, enabling researchers to train more robust machine learning models and improve their generalization performance.

Quantum Simulation

QGANs can simulate quantum systems and phenomena by generating samples from quantum data distributions, allowing researchers to study complex quantum phenomena, optimize quantum algorithms, and explore quantum materials efficiently.

Privacy-Preserving Machine Learning

QGANs can be used to generate privacy-preserving synthetic data samples that preserve the statistical properties of the original data distribution while concealing sensitive information, enabling secure and privacy-preserving machine learning tasks.

Quantum-Enhanced Machine Learning

By leveraging the computational advantages of quantum computing, QGANs offer potential enhancements to classical generative modeling techniques, enabling more efficient and accurate data generation and simulation in various machine learning tasks.

In summary, quantum generative models, particularly QGANs, represent a promising approach to generative modeling and data generation using quantum computing techniques. With applications ranging from synthetic data generation to quantum simulation and privacy-preserving machine learning, QGANs offer potential advantages over classical generative modeling techniques, paving the way for advancements in quantum-enhanced machine learning and data analysis.

APPLICATIONS AND CHALLENGES

Real-World Applications of Quantum Algorithms and Quantum Machine Learning

Quantum algorithms and quantum machine learning hold immense promise for a wide range of real-world applications, spanning various industries and scientific disciplines. Some notable applications include:

Cryptography and Security

Quantum algorithms, such as Shor's algorithm, pose a threat to classical cryptographic systems by efficiently factoring large integers. However, quantum cryptography offers potential solutions for secure communication protocols, such as quantum key distribution (QKD), which leverages quantum properties for secure key exchange.

Optimization and Operations Research

Quantum algorithms, such as the quantum approximate optimization algorithm (QAOA), offer potential solutions for optimization problems in logistics, supply chain management, and resource allocation. These algorithms can efficiently tackle combinatorial optimization problems, such as the traveling salesman problem or graph partitioning, enabling more efficient resource utilization and decision-making.

Drug Discovery and Materials Science

Quantum simulation algorithms enable researchers to simulate molecular structures, predict material properties, and optimize chemical reactions efficiently. These capabilities have applications in drug discovery, materials design, and catalyst optimization, accelerating the development of new pharmaceuticals, materials, and chemical processes.

Artificial Intelligence and Machine Learning

Quantum machine learning techniques, such as quantum neural networks and quantum generative models, offer potential enhancements to classical machine learning algorithms. These techniques can improve pattern recognition, data analysis, and optimization tasks, enabling more accurate predictions and insights from data.

Challenges and Limitations of Current Quantum Computing Technologies

Despite the promising applications of quantum algorithms and quantum machine learning, current quantum computing technologies face several challenges and limitations:

Qubit Coherence and Error Rates

Quantum computers are susceptible to noise and errors, which degrade the coherence of qubits and limit the accuracy of quantum computations. Improving qubit coherence times and reducing error rates are critical challenges for scaling up quantum computing technologies and achieving reliable quantum computation

Hardware Scalability

Building large-scale quantum computers with a sufficient number of qubits and connectivity poses significant engineering challenges. Current quantum hardware platforms, such as superconducting qubits and trapped ions, face limitations in scaling up to the thousands or millions of qubits required for practical applications.

Algorithmic Design and Error Correction

Developing efficient quantum algorithms and error correction techniques is essential for realizing the full potential of quantum computing. Designing quantum algorithms that exploit the strengths of quantum computation while mitigating the impact of noise and errors is a non-trivial task that requires interdisciplinary expertise and innovation.

Interfacing with Classical Systems

Integrating quantum computers with classical systems and infrastructure presents technical challenges in data transfer, communication protocols, and software compatibility. Developing efficient interfaces and protocols for exchanging information between quantum and classical systems is essential for integrating quantum computing technologies into existing workflows and applications.

Perspectives on Future Developments and Opportunities for Research

Despite the challenges and limitations, the future of quantum computing holds tremendous opportunities for research and innovation:

Hardware Advances

Continued advances in quantum hardware technologies, such as qubit coherence times, error correction codes, and fault-tolerant architectures, will enable the construction of larger and more reliable quantum computers. Emerging technologies, such as topological qubits and quantum error correction, offer potential solutions for improving qubit coherence and error rates.

Algorithmic Innovation

Innovations in quantum algorithm design, optimization techniques, and quantum error correction algorithms will drive progress in quantum computing. Developing hybrid quantum-classical algorithms, quantum machine learning techniques, and quantum simulation algorithms will unlock new capabilities and applications for quantum computing technologies.

Interdisciplinary Collaboration

Collaboration across disciplines, including physics, computer science, mathematics, and engineering, is essential for advancing quantum computing research. Interdisciplinary research teams can leverage diverse expertise and perspectives to tackle complex challenges and drive innovation in quantum computing technologies.

Industry Partnerships and Applications

Collaboration between academia, industry, and government agencies is essential for translating quantum computing research into practical applications and technologies. Industry partnerships can accelerate the development of quantum hardware, software, and applications, driving commercialization and adoption of quantum computing technologies.

In conclusion, quantum algorithms and quantum machine learning offer promising opportunities for solving real-world problems and advancing scientific knowledge. Despite the challenges and limitations of current quantum computing technologies, ongoing research and innovation hold the potential to overcome these obstacles and unlock the transformative capabilities of quantum computing for diverse applications and industries. Collaborative efforts across disciplines, industry partnerships, and continued investment in research and development are essential for realizing the full potential of quantum computing technologies in the years to come.

CONCLUSION

In this paper, we have explored the groundbreaking advancements in quantum computing and machine learning, delving into the intricacies of quantum algorithms, hybrid quantum-classical models, and the potential applications of quantum computing technologies in various domains. Our analysis has revealed both the immense promise and the significant challenges facing the field of quantum computing and machine learning.

Summary of Key Findings

Key findings from our exploration include:

Quantum Algorithms

We have examined seminal quantum algorithms such as Shor's algorithm for integer factorization and Grover's algorithm for unstructured search. These algorithms demonstrate the potential of quantum computing to solve computationally intensive problems exponentially faster than classical algorithms, with implications for cryptography, optimization, and simulation tasks.

Quantum Machine Learning

We have discussed the emergence of quantum machine learning techniques, including quantum neural networks and quantum generative models. These models leverage quantum computing principles to enhance pattern recognition, data analysis, and optimization tasks, offering potential advantages over classical machine learning approaches.

Real-World Applications

We have explored the real-world applications of quantum algorithms and quantum machine learning across various industries and scientific disciplines, including cryptography, drug discovery, materials science, and artificial intelligence. These applications highlight the transformative potential of quantum computing technologies for solving complex problems and driving innovation.

Challenges and Limitations

Despite the promising applications, we have identified challenges and limitations facing current quantum computing technologies, including qubit coherence, hardware scalability, algorithmic design, and interfacing with classical systems. Addressing these challenges is essential for realizing the full potential of quantum computing and machine learning.

Implications for the Future

The future of quantum computing and machine learning holds tremendous potential for innovation and discovery. Advancements in quantum hardware, algorithm design, and interdisciplinary collaboration will drive progress in the field, unlocking new capabilities and applications. Quantum computing technologies have the potential to revolutionize industries, transform scientific research, and address some of society's most pressing challenges.

Moreover, the integration of quantum computing with classical systems and infrastructure will pave the way for hybrid quantum-classical approaches, enabling more

efficient and powerful computational workflows. Quantum-enhanced machine learning techniques will augment classical machine learning algorithms, offering new insights and capabilities for data analysis, pattern recognition, and optimization tasks.

Call to Action

As we look towards the future, it is imperative to foster further exploration and collaboration in the field of quantum computing and machine learning. Researchers, industry partners, and policymakers must work together to overcome technical challenges, accelerate innovation, and realize the potential of quantum computing technologies.

We call upon researchers to continue pushing the boundaries of quantum computing and machine learning, exploring new algorithms, developing novel applications, and advancing quantum hardware technologies. Collaboration across disciplines, industry partnerships, and investment in research and development are essential for driving progress and realizing the transformative impact of quantum computing technologies.

Furthermore, we encourage policymakers and funding agencies to support and prioritize research in quantum computing and machine learning, recognizing the importance of these technologies for scientific advancement, economic competitiveness, and societal progress. By working together, we can harness the power of quantum computing and machine learning to address global challenges and shape a brighter future for humanity.

In conclusion, the journey towards realizing the full potential of quantum computing and machine learning is both challenging and exhilarating. By embracing collaboration, innovation, and perseverance, we can unlock new frontiers of knowledge and usher in a new era of computational discovery and exploration.

ABSTRACT

Cloud computing technology is one of the biggest milestones in leading us to next generation technology and booming up business and IT field. Cloud computing, the technology that makes it possible for computing resources to be provisioned to clients / subscribers over long distances, as well as its component technology – virtualization, which makes it possible for multiple guest systems to co-reside on a single host machine and share the computing resources of the host, have both become very popular technologies that have witnessed giant improvements in the 21st century.

cloud computing, virtualization, hypervisor, host machine.

INTRODUCTION

Cloud computing is one of the most useful technologies that is been widely used all over the world. It generally provides on demand IT services and products. Virtualization plays a major role in cloud computing as it provides a virtual storage and computing services to the cloud clients which is only possible through virtualization [1]. Cloud computing is an internet-based computing with the ability to share resources on-demand and dynamically, but most of the IT people do not pay attention to one point and is the evolution of cloud computing could not be possible without existing of other technologies like virtualization technology [3]. Virtualization is the technology that allows multiple Virtual Machines (also called guest machines) to run on a single physical machine (also called host machine) and share the resources of the physical machine [2].

CLOUD COMPUTING

Cloud computing is one of the most useful technology that is been widely used all over the world. It generally provides on demand IT services and products. Virtualization plays a major role in cloud computing as it provides a virtual storage and computing services to the cloud clients which is only possible through virtualization [1]. Cloud computing is an internet-based computing with the ability to share resources on-demand and dynamically, but most of the IT people do not pay attention to one point and is the evolution of cloud computing could not be possible without existing of other technologies like virtualization technology [3]. Virtualization is the technology that allows multiple Virtual Machines (also called guest machines) to run on a single physical machine (also called host machine) and share the resources of the physical machine [2].

In cloud computing space/ memory is virtually allocated to the users in the servers which requires a host(platform) on which hypervisor(software which interacts with the hardware) runs. The virtualization model is consisting of cloud users, service models, virtualized models and its host software and as well as their hardware. It is based on three service models that are SAAS (software as a service) , PAAS (platform as a service) and IAAS (infrastructure as a service). SAAS provides applications to the cloud users to full fill their needs and demands. PAAS provides the cloud users a common platform on which they can execute their applications and IAAS provides the security and hardware to maintain the cloud resources [3] Host : for virtualization the hypervisor software runs on a virtualization platform i.e. Is host. Hypervisor : the software program which handles the virtual machine to work under the virtually simulated environment is called hypervisor.

With the help of virtualization we can increase the use of resources available to us in many to get more benefits. We should virtualize because of the following reasons : a. Isolation among users: one user should be isolated from the other users so that he/she may not get information about the others user's data and usage and cannot even access other's data . b. Resource sharing : a big resource can be fragmented into multiple virtual resources so that it can be used by multiple users using virtualization technique. c. Dynamical resources : reallocation of resources such as storage and computational resources is very difficult but if they are virtualised then they can be easily re-allocated. d. Aggregation of

resources : the small resources available can be increased at a large extent with the help of virtualization.

Virtualization is a very fundamental technology that lies at the heart of the operations of modern Cloud Computing Infrastructure . This technology is important to cloud computing because it provides the abstraction that cloud computing enjoys by taking a physical resource such as a server and dividing it into virtual resources called virtual machines (multiple subscribers). In case of server consolidation, many small physical servers are replaced by one larger physical server, to increase the utilization of costly hardware resources such as CPU time.

BENIFITS OF VIRTUALIZATION TECHNOLOGY a. Virtualization is one of the cost-saving, hardware-reducing and energy-saving technique. b. It helped to make cloud computing more efficient and eco-friendlier. c. A big step towards new technology making life easier and better.

VIRTUALIZATION:

Virtualization is basically making a virtual image or “version” of something such as server, operating system, storage devices or network resources so that they can be used on multiple machines at the same time. The main aim of virtualization is to manage the workload by transforming traditional computing to make it more scalable, efficient and economical. Virtualization can be applied to a wide range such as operating system virtualization, hardware-level virtualization and server virtualization. Virtualization technology is hardware reducing cost saving and energy saving technology that is rapidly transforming the fundamental way of computing.[1]

Virtualization could occur in various forms. It could be server-based, system based, storage virtualization, desktop virtualization or network virtualization. It could also be hypervisor-based (if a piece of software known as a hypervisor or virtual machine monitor is used to achieve virtualization) or non-hypervisor-based [2]

Some of the prospects which to virtualization and CC have been revealed in researches by, and to include: more favourable policy enactments and implementations, ubiquity, centralized storage and accesson-demand, data portability across various cloud platforms, increased consumer-base for private and public clouds, less security concerns and more

standardization. An October 2014 survey carried out by Forrester Consulting on behalf of Infosys revealed by 81% of companies surveyed that cloud computing is no longer driven by cost savings anymore, but by agility, simplicity and a unified view of IT. This result is expected to increase exponentially within the next few years as more organizations are expected to turn to the cloud for these reasons.

Two additional factors that have significantly distinguished this new technology from its predecessors and greatly altered its market dynamics in recent years are the speed, dynamism and “far-reach” of the Internet, which makes it possible to transport and deliver computational resources at high speeds, across long distances, and at reduced cost; and the ubiquity of personal computers coupled with the tendency to own computers that satisfy “peak” against “average” need for computational power, directly leaving a good reserve of computational resources idle . Today, Cloud computing is gradually coming to bear in reality as the most formidable path to business and organizational growth and has gained rapid interest and prominence over the past decade. The reason for this rapid growth cannot be far-fetched. Cloud computing simply makes very efficient and flexible, the task of scaling different business services to meet very dynamic business needs; the shared infrastructure and services they provide make it a more prudent venture when compared with other traditional approaches of hosting each of these infrastructure and services locally.

PLACE OF VIRTUALIZATION IN CLOUD COMPUTING:

Virtualization is one of the major components of cloud computing that helps to emergence of cloud computing. To understand cloud computing it is important to understand the concepts like network virtualization or storage virtualization. The main components of virtualization in the cloud are virtual machines, because all of the operating systems and applications are inside them. They are like a container which isolated and separated from each other, even in the same physical host. Based on the basic role of cloud as-pay-you-go, the vendors give you that ability to access these provided virtual machines and in some cases they will make these virtual machines like an actual computer and you can purchase them for a limited time and take advantage of this ability without any worries about how they operate. That thing you are purchasing is the availability of these services.

Vendors in exchange promise to give you these services without any interrupt that make the availability in high level.

VIRTUAL MACHINE

“A virtual machine (VM) is an abstraction layer or the environment between hardware components and the end-user.” Virtual machines have an ability to run any operating systems on them and in special cases it referred to as virtual hosts. The interaction between the guest operating systems which are running in virtual machines (VM's) and resources which are available for sharing between virtual machines, provided in two ways. One is by using the host operating system, or another, a piece of software which called as the hypervisor and acts like mini operating system, can run many virtual machines. Hypervisor also call as virtual machine monitors (VMM). They are able to share system hardware components such as CPUs, controllers, disk, memory, and I/O among virtual servers[3].

HYPERVISOR

In virtualization technology, there is one piece of software that allows the physical servers can have multiple instances of virtual machines and it called as Hypervisor. These instances are virtual machines that create in virtualization environment and the hypervisor is responsible for supervising and controlling these machines communication, resource sharing and reallocating the virtual machines. This connection between virtual parts and physical parts is very important in a cloud computing environment and it is the only path to the dynamic data centers which was our solution for new data centers. There are two types of hypervisors. The first is called as “Bare Metal Hypervisor” and the second one is called as “Hosted Hypervisor”.

One of the principal questions in this concept is: “are virtualization and cloud computing same?” The answer for this question is “No”. The virtualization is the ace of the layers in cloud computing architecture, but it has a major role in most of the abilities of cloud systems. Virtualization is one of the technologies that given the ability to create the abstraction of computer with ability to perform all the behavior of the actual computer. With the aid of these concepts, we can create other new technologies and one of them is cloud computing technology. But we can say these two concepts are closely related to each other. The

virtualization is an overall concept that holds lots of abilities for creating a computers or computer groups virtually and make network of these virtual computers. The most important thing is the virtual computer completely acts like real computers and any problem we can visualize for physical computer, can be appears here. For example, if in network with the physical computers we have a serious problem with the attackers of open ports or even unauthorized users, the same problem also here appears itself. It implies that all the security risks and security issues are in physical network, we will face it in virtual network of virtual computers. With the help of all these facilities that virtualization provided for us, computer scientists took advantage of that and with few changes and controllers developed the cloud computing technology.

SCALABILITY OF CLOUD

Scalability of cloud also is one of the achievements which its existence because of virtualization. The dynamic attribute of the virtualization is helping the cloud providers that offer such an environment that any request can respond on-demand. In cloud computation process, if any of virtual machines need to increase one of the resources, it can be increased by the cloud management system. Even if a user needed to increase any of the resources, as service level agreement, the cloud management system can manage these resources and user environment can be expanded. This expansion and shrinking the available resources for active virtual machines is ability of dynamic virtualization technology. But now a days, most of the people who are talking about cloud computing, just talks about the scalability of cloud without mentioning anything about virtualization. This way of reviewing the abilities without reviewing the background of it, make it more difficult to understand and discuss.

In the old days the data center technicians need to go through in the hard work of cabling, but nowadays by help of virtualization the cables are gone (of course not entirely). Instead of physical connection between two physical computers, we can virtually connect two of virtual computers together. By help if virtualization even cables converted to the virtual cables and it reduced the time which the data center technicians spend on the cabling and maintaining the cables.

STORAGE VIRTUALIZATION

In data centers the data storage is little different. The physical storages are not directly connected to the servers; they are connected to the servers through the network. One of the most popular protocols use for storage virtualization is a storage area network (SAN) and network attached storage (NAS). For the fast interaction the use fiber channel and the protocol they are using is iSCSI (internet Small Computer System Interface). These protocols allow block storage to be accessible over the network by using a TCP/IP protocol. They use TCP for reliable communication.

The storage virtualization also relies on a Redundant Array of Independent Disk (RAID) technology to protect data from lost in any physical failure occurs. In new virtual storage systems, they use the latest technology which called as Redundant Array of Independent Node (RAIN) rather than RAID. This new technology helps availability of data even if several servers go down . The significant point of the storage virtualization is to hide geographical positions of the data over the cloud environment. For this significant point of the storage virtualization maps the logical storage to the physical storage as blocks of data . In storage virtualization still the management of the data which can be distributed among the network is the one of the important issues in cloud storage . Vendors promise to the scalability and on-demand of their cloud make the most important challenges for cloud providers. Performance and transfer rate became important issues not only for the cloud providers, but it will affect the user experience. To overcome this kind of problems, the bandwidth needs to be increased otherwise it can be a bottleneck for data transfer ; and it becomes a serious problem for the providers which affect the cost of services if they do not face the bandwidth limitation. Another key issue for the cloud storage is the data security. Because of the multi tenancy of the cloud, user's data may distribute among the different physical storage or even over other data centers. The management system should controls how own the data and should have access to the data. Transferring data over the network without proper protection may cause the security risk of user data .

CONCLUSION

In new computer technologies, we cannot push the one concept back and highlight the other one. All concepts in the computer world are intertwined together; we should not break them apart and discuss them individually. In this case by pushing the important concept of virtualization, we broke down the evolutionary chain between of technologies in the computer world and make the confusion. Without understanding the concept of virtualization, it is very difficult to realize the cloud computing concept.

ABSTRACT

The construction sector has almost universally embraced the critical role of collaboration in driving improved project outcomes and mitigating risk. In communication and information sharing between architects and designers, contractors, subcontractors and customers, technology delivers capabilities to enable and promote mutual understanding among the many parties involved in a project. Virtual Reality (VR) is one such technology. This paper discusses the value of VR as a visualisation tool which brings to the construction sector a deeper understanding of the anticipated outcomes of a project as it develops, and the potential problems it may present along the way. VR is no longer viewed as simply an 'addon' as designs near the finishing line, using visualisation just to show how wonderful the project will end up looking.

INTRODUCTION

As far back as 2018, VR was a rapidly emerging theme in construction. A GOV.UK announcement at the time, for example, attached transformational capabilities to the technology of VR: "Virtual Reality to revolutionise UK's construction sector". Since then, it has done so. Innovation, by definition, is about doing new things or doing old things differently and better. It is how successful businesses differentiate themselves and strengthen their competitive advantage; improving efficiencies and results, and challenging traditional routes to achieving them. The paper looks at perceived barriers to adoption, and outlines how any business can get started on a revolutionary, innovative, collaborative and,

above all, efficiency-enriching journey. The paper also includes a 'Top 10' checklist of the major benefits: The value of VR in design and construction.

Fig.1. Augmented reality (AR) and Virtual reality (VR): shaping the future of immersive experiences

THE TOP 10 BENEFITS OF VR IN DESIGN AND CONSTRUCTION

Virtual Reality turns up the dial on focus and attention. It sends environmental sense stimulation to the brain from the eyes. The optical systems manufacturer, Zeiss, states that:

“By far the most important organs of sense are our eyes. We perceive up to 80% of all impressions by means of our sight”.

Therefore, if you harness that 80% in a VR environment, you bring 100% attention to the project under review. This leads to saving time and money. It precludes misunderstandings. It prevents any key points being missed. If you have your meeting in VR with clients and stakeholders, their attention is 100% within the boundary of the VR immersion. They are focused, they concentrate and they appreciate what they are seeing more completely. With this overview in mind, here are my top 10 benefits of VR.

1. **Better Project Planning:** Viewing and testing in a virtual environment reveals valuable information at every stage of development. This insight helps identify areas to review in the early design stages and the pre-planning stages of construction. Construction order and supply availability becomes smoother and more precise since all teams will be involved at the earliest time, gaining the opportunity to contribute further to their area of involvement in the initial design stages.

2. Clash Detection in Visual Form: VR helps to identify conflicts between design and the requirements of engineering professionals and subcontractors.

3. Improving Safety Measures, Advising Actions in Case of Emergency, and Clearly Identifying Evacuation / Escape Routes: Final stages of design allow fire and emergency routes and procedures, for final building occupants as well as site operatives during the build, to be rigorously identified. This process can be used to design and form a virtual orientation programme, enabling familiarity with the building. Adding to this, Augmented Reality can be used to help during practice drills in fire escape situations; wearing the AR glasses and seeing the fire route overlaid in the real world.

4. Build Safer: Provide phased safety on site, pre-empting difficult areas during construction.

5. Improved Project Workflow: Smoother transition between design and construction as everyone gains a clear picture of how the finished project emerges as intended. This eliminates isolation between teams and phases.

6. Try Before You Build: Construction areas can be explored and practiced in VR. Equipment placement, temporary works, potential danger can be highlighted and factored into the phases

7. Demonstrate Compliance: VR can demonstrate that the model is built to specification and building regulations.

8. Collaboration is Quickly Effective: All interested parties can have important input. An example of more effective consultation with impacted stakeholders would be having doctors and nurses involve in spatial design in the design of a hospital. The public could also be offered the opportunity to view a development, smoothing the way towards more informed acceptability and greater understanding of the ultimate impact of a development on the community.

9. Superior Customer Experience: Customer experience is achieved to a depth and with clarity of understanding in a way not achievable with any other medium: "Try before you buy".

10. Line of Sight: A simple benefit I have seen many times in recent training sessions is that we have line of sight from any given point. Once again, a benefit unattainable with any other type of technology.

The role of augmented reality

Alongside VR, Augmented Reality (AR) is becoming an essential concept in design and presentation. The main function of AR is to overlay objects or features onto real visual content through either a headset or a device such as a smartphone or tablet.

What the eye can't see...AR is also extensively used in situations where a 3D model is projected at full scale in an environment. For example, whilst being on site or in an existing build, users can view new services behind walls.

As with VR, AR offers an instant feel for, and comprehension of, spatial impact on a project. Getting involved in these developments is crucial in our ever-increasing demand to satisfy the full creative design process. We literally see from all angles, potential reviews and changes. Thus, avoiding costly unforeseen mistakes.

BARRIERS TO ADAPTION

Construction is going digital

There are still companies who dismiss VR as superficial 'show business' in AEC; seeing it as just another way of presenting glossy marketing materials to clients. Although undeniably more engaging than a brochure, and more easily grasped by industry outsiders than a 2D drawing, or even a 3D model, VR is still considered by the unconvinced to be not much more than a tool for sales.

Once you strip away the 'showmanship perception' of VR, you find a rich source of insight which does far more than just improve the customer experience. You find a means of understanding spatial relationships in a building or a project that can enhance safety aspects, promote greater understanding of roles and directions, and support information sharing in a way that everybody involved in a project can understand and benefit from.

Building Information Modelling (BIM) has played a catalytic role in driving transformation in the industry, emphasising the importance of sharing information and the immeasurable value of collaboration. Covid-19 was a further catalyst in accelerating the adoption of remote working practices, as outlined earlier.

Understanding spatial relationships

To be able to collaborate, people depend on information. This was traditionally provided in the form of documents and spreadsheets, the sharing of which was accelerated through the advent of email, and has now expanded into real-time tools for collaboration, from

common data environments, to screen and model sharing, to video conferencing and mobility. This is where VR comes in, helping, alongside Augmented Reality, to transform design, construction and the operation of the built environment.

The origins of vr technology: dispelling the myth

Digital construction is driving resounding change in collaboration, and the sharing of information, to the betterment of project outcomes and the greater sustainability of the built environment. The question that companies across the construction sector value chain should be asking at this point in time is not why they should adopt VR, but how soon can they do so. I'd like to explain why they should be asking that question.

Playing the game, for real

The entertainment industry has often initiated technologies and ideas that have passed into industry by being harnessed for broader ranging technology deployment. A good example is what's known as the 'gamification of IT'. This is about picking out those nuggets of value from game playing that get round the complex aspects of using technology that can slow down or even prevent adoption.

When users are resistant, old ways persist and the inefficiencies, that the technology was designed to eliminate, continue to occur. The design of the 'intuitive' user interface using icons and simple signposting and reducing instructions to the minimum, is a direct descendant of game play.

Keep it simple VR

provides visual understanding of an environment by immersing those who use it into the three-dimensional world. This is the world we live in, work in, and build in. Collaboration in understanding this world, via a tool that faithfully reproduces and represents 3D reality, has logic on its side.

The concept is flawless. Anything less than a view that is as close to reality as it's possible to get is, the converse logic dictates, inherently flawed; open to varying interpretations and one step removed, if not more, from the object it represents. spatial awareness can never be a function of flat representation.

Prior to the advent of 3D models, traditional two dimensional drawings had long been the means used to describe design. The more complex the elements within a project, the greater the proliferation of drawings; reams of them being a daunting prospect to any project participant let alone those not of a technical bent.

It was a prerequisite of viewing and understanding a 2D design that anybody looking at the design would have an intrinsic familiarity with visualisation such that they could convert 2D data in their heads to imagine and envisage the 3D project.

It was a complex and instantaneous cognitive process of imagining what something could look like by taking in visual cues composed entirely of elements that it didn't look like. Interpretation was all important. Misinterpretation was thus an ever-present danger.

Assuredly, many Towers of London, Cathedrals, Palaces, Historic Places of Learning and Stately Homes have come to fruition enduringly enough. As they say, however, that was then, and this is now. We do things differently. Our duty as an industry and our responsibility to the future, is to do things better.

In a complex technological world, simplicity rules. The more that people understand something, the more warmly they respond to it, see its value, and start using it; comfortably and confidently

VR TECHNOLOGIES

Inclusive, Immersive, Persuasive

Virtual Reality is not a complex technology. It's a technology that strips out complexity and promotes faster understanding and easily comprehensible sharing of the proposed physical status of a construction and the constituent parts within it.

At its most basic it's about putting on a headset and seeing an all-round view of a building, a room, or any aspect of a construction project where clarity is required and understanding is important. That means every aspect of a project; every project.

User Friendly Technology

When 3D scaled models came into the mix in architecture and engineering, they significantly improved perceptions of space and volume. They also introduced another factor in making it possible to represent the aesthetic of the overall project. On your journey into adopting Virtual Reality, you will find that people are confident about being immersed into a new world.

Among construction professionals, initial apprehension and concerns are fading as it becomes increasingly evident that the visual immersive experience allows constructive design observations. For this reason, VR is increasingly becoming an essential tool in the design process.

While a 3D model on the desktop gives a visual understanding of the overall project, it is however, a 'bird's eye' view. Far more encompassing, VR allows the viewer to be in any position and scale within the design or outside the design. This flexibility offers significant design options to be considered. It introduces the ability to spot inaccuracies not fully apparent in the 2D drawing or the physical 3D model. Immersing in the VR world is the only way to fully absorb the spatial interpretation of a design.

Practical Matters

It may appear that a technology that improves the way we see and interpret things – itself a bold and transformative claim – might imply complex adoption and implementation. This is not the case. The process of transposing a CAD design into a VR experience is simple. A 3D view in Revit can quickly be converted into a VR visual through a number of solutions, allowing the geometry, together with textures, to be viewed through an interactive viewer either on screen (with navigation with a mouse and keyboard) or more impressively with a VR headset such as HTC Vive, Oculus Rift, and Varjo Aero.

The particular solution you select depends on the uses you have identified for VR, from the creation of large scale environments to make something like the campus experience come alive, through to specific uses, either for client sharing or for work-in-progress visibility.

The Bigger Picture

To create an inspiring overview there is a combination of three solutions which works in an integrated fashion; starting with the Revit model, then taking the model into 3ds Max to create detailed textures and finishes, and then taking the result into Unity or Unreal Engine 5 for full immersive VR visualisation. You can create rich scenarios to bring interactive experiences that engage viewers. In this case Autodesk are partnering with Unity, and Epic Games with Twinmotion.

There are some excellent applications for the process of getting the 3D model into a VR and AR situation. The following solutions are all supported by Autodesk for use in association with Revit:

There are five easy-to-work with solutions:

1.IrisVR:

The fastest way to start There is a solution that enables you to get going with VR almost instantly but does not link into BIM 360. In this regard it is more about bringing the 'wow' factor into play to demonstrate to clients where the project is going and how it can look,

giving them the chance to express meaningful input on finishes and other choices where choice is relevant. With IrisVR you simply load your 3D file and click launch, and you're in the VR world. This is a fast way to get going with VR, particularly where BIM is not of priority or concern on a project.

2. InsiteVR: Cloud-share the vision

The sharing of VR views between locations, even internationally, accelerates understanding and empowers decisions in a powerful way. InsiteVR's Resolve enables remote collaboration meetings in the Revit model, in the cloud, linking with BIM 360. Participants can annotate the view in real-time and see each other's annotations as they are made.

3. Enscape:

Create a live link from BIM to a virtual walkthrough For conceptual designs, Enscape enables operatives to move around the Revit model but is not appropriate for collaboration. This is more a work-in-progress tool. The user has the software installed on the system (not a cloud-based or Internet shareable solution) and simply opens it as required to do walkthroughs. It is a perfect tool for enabling designers to 'get' the final picture as the project develops. They can add textures and surface finishes to gain a sense of visual impression, and a sense of volume. The views can be shown to clients, but not remotely; they have to be at the designer's screen.

4. VisualLive:

Overlay services details onto real world geometry Augmented Reality (AR) is bringing a level of spatial understanding to the building services industry never before possible. With VisualLive you can overlay a model onto the natural (existing) view in a process known as 'mixed reality'. This provides a heads-up display (HUD) where, for example, you can look at real world walls via a HoloLens or even a tablet and then overlay the services pipes behind them to see exactly how they will lay out. Effectively, the overlay is a model and what it is overlaid onto is real world scenario

CONCLUSION

Build in sight before building on-site It is no bad thing that VR is considered by some as a sales tool. If that works for you and your purposes then long may it do so. Perhaps, however, its use can be qualified by referring to it as work-in-progress consultancy. If rooms

can be changed, entire projects can be changed. Buildings can be inserted into a campus, access and egress can be repositioned; orientation can swivel in any direction practicable. Any option can be explored, before any commitment is made. VR is immersive but, more than that, it is inclusive. VR invites and inspires collaboration. Its use demonstrates transparency. It serves as a customer-centric opportunity not just to achieve greater customer satisfaction through an inclusive customer experience, but also to gain thoughts and opinions, feedback and buy-in as a project develops. VR also invests the creative zone, the place in which designers and architects work, with a deep level of focus that extends beyond the VR world and back into reality. In my experience I have met with many professionals in this field who say they come back from the VR experience with a greater sense of clarity about how a project is unfolding. They have a faster understanding of how things will look. They see things clearer. I believe this is because they have had a glimpse of the future; they then understand better how to get there. The journey into a new vibrant, practical and relevant way of looking at the future you plan for the built environment can be faster than you may imagine. Once you arrive in the VR world you may then start to imagine faster than you ever have before.

ABSTRACT

This paper examines about the process parameters like electrolyte concentration, pulse on/off ratio, machining voltage, voltage frequency, tool vibration frequency on over cut and MRR (Material Removal Rate), Electrical discharge machining (EDM) is one of those nonconventional processes that is used frequently for shaping titanium alloys with their respective pros and cons. However, a good understanding of this process is very difficult to achieve as research results are not properly connected and presented. Therefore, this study investigates different types of EDM processes such as, wire EDM, die-sink EDM, EDM drill and hybrid EDM used to machine titanium alloys. Machining process suffer from lower material removal rate and high tool wear while applied on titanium alloys. Formation of recast layer, heat affected zone and tool wear is common in all types of EDM processes. Additional challenge in wire EDM of titanium alloys is wire breakage under severe machining conditions. The formation of TiC and TiO₂ are noticed in recast layer depending on the type of dielectrics, an experiment is also carried out in this project to examine and optimize the impact of variables for machining, such as spark on time, discharge current, and voltage based on the Taguchi strategy method. The Titanium work piece is being used to perform this experiment with a copper tool (electrode) with three different diameters, and EDM oil has also been selected as a dielectric medium. The experiment is conducted using Taguchi's L27 orthogonal array. S/N ratio is determined to examine the effect of input

factors precisely. For investigation and clarification, the curve is graphed between the mean S/N ratio also for the rate of material removal and tool wear rate with three machining parameters (current, spark on time, voltage)

INTRODUCTION

Electro Discharge Machining is a useful method because of its unique material removal process, improved precision and control, environmental friendliness, and the ability to machine any metallic substance, regardless of its hardness. The materials which are hard and difficult to machine using conventional methods are machined using this method. An Electro discharge machining is also known as the non-traditional machining in which the material is removed by an anodic dissolution during an electrolytic process.

Hence, non-traditional machining methods are applied to process titanium alloys. Amongst different non-traditional machining procedure, EDM is widespread owing to its adaptable ability to cut difficult-to-machine materials in complex shapes the work piece is dipped in dielectric liquid to create a encouraging surrounding for electric sparks to happen Spark erosion takes place in the vicinity of electrodes and forms expected three/two dimensional figures by melting/evaporating the work piece material.

It is a promising technique for various materials irrespective of its toughness and hardness, as long as those are conductive electrically. In this process, an electrode acts as a tool and the work piece material itself act as other electrode. The dielectric liquid acts as heat absorber and carries heat and debris away from the machining zone.

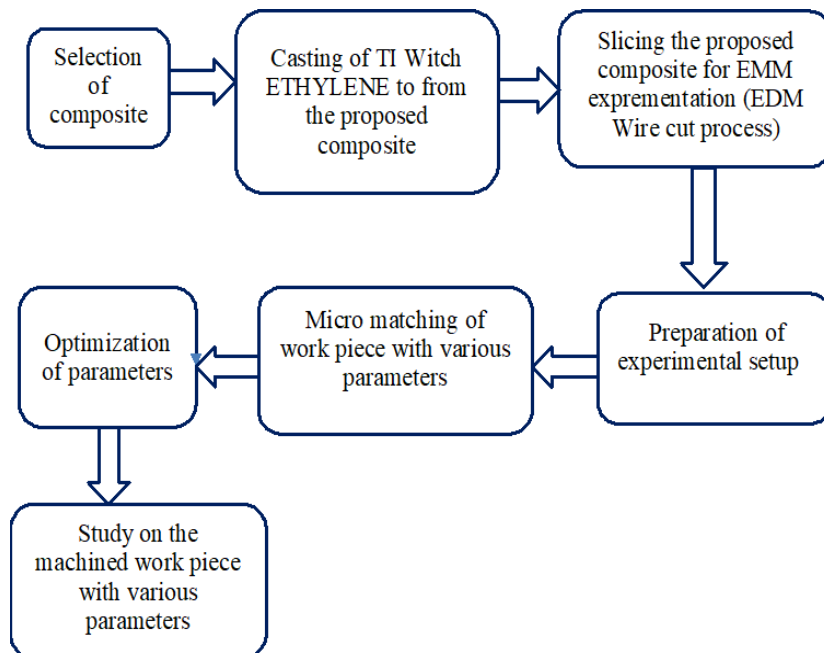

Specific heat and electric resistivity of titanium alloys or melt this material during EDM process. In addition, poor thermal expansion coefficient and thermal conductivity of titanium alloy makes the process more challenging in terms of heat transfer and cause localized discharges, arcing, short - circuiting and tool failure. These scenarios decrease the efficiency of the process, results in lower material removal rate (MRR) or even damaged machined surfaces.

Electrical discharge machining (EDM), also known as spark machining, spark eroding, die sinking, wire burning or wire erosion, is a metal fabrication process whereby a desired shape is obtained by using electrical discharges (sparks) Material is removed from the work piece by a series of rapidly recurring current discharges between two electrodes, separated

by a dielectric liquid and subject to an electric voltage. One of the electrodes is called the tool- electrode, or simply the tool or electrode, while the other is called the work piece-electrode, or work piece. The process depends upon the tool and work piece not making physical contact. Extremely hard materials like carbides, ceramics, titanium alloys and heat treated tool steels that are very difficult to machine using conventional machining can be precisely machined by EDM.

When the voltage between the two electrodes is increased, the intensity of the electric field in the volume between the electrodes becomes greater, causing dielectric break down of the liquid, and produces an electric arc. As a result, material is removed from the electrodes. Once the current stops (or is stopped, depending on the type of generator), new liquid dielectric is conveyed into the inter-electrode volume, enabling the solid particles (debris) to be carried away and the insulating properties of the dielectric to be restored. Adding new liquid dielectric in the inter-electrode volume is commonly referred to as flushing. After a current flow, the voltage between the electrodes is restored to what it was before the breakdown, so that a new liquid dielectric breakdown can occur to repeat the cycle.

METHODOLOGY

TITANIUM AND ITS PROPERTIES

It is a strong metal with low density that is quite ductile (especially in an oxygen- free environment), lustrous, and metallic-white in color. The relatively high melting point (1,668 °C or 3,034 °F) makes it useful as a refractory metal.

Titanium Material

Titanium can be alloyed with iron, aluminum, vanadium, and molybdenum, among other elements, to produce strong, lightweight alloys for aerospace (jet engines, missiles, and spacecraft), military, industrial processes (chemicals and petrochemicals, desalination plants, pulp, and paper), automotive, agriculture (farming), medical prostheses, orthopedic implants, dental and endodontic instruments and files, dental implants, sporting goods, jewelry, mobile phones, and other applications.

The two most useful properties of the metal are corrosion resistance and strength- to- density ratio, the highest of any metallic element. In its unalloyed condition, titanium is as strong as some steels, but less dense. There are two allotropic forms and five naturally occurring isotopes of this element, ^{46}Ti through ^{50}Ti , with ^{48}Ti being the most abundant (73.8%).

WORKING PROCEDURE

Electrical Discharge Machining

Electrical discharge machining (EDM), also known as spark machining, spark eroding, die sinking, wire burning or wire erosion, is a metal fabrication process whereby a desired shape is obtained by using electrical discharges (sparks). Material is removed from the work piece by a series of rapidly recurring current discharges between two electrodes, separated by a dielectric liquid and subject to an electric voltage. One of the electrodes is called the tool-electrode, or simply the tool or electrode, while the other is called the work piece - electrode, or work piece. The process depends upon the tool and an electrical discharge machining. When the voltage between the two electrodes is increased, the intensity of the electric field in the volume between the electrodes becomes greater, causing dielectric break down of the liquid, and produces an electric arc. As a result, material is removed from the electrodes. Once the current stops (or is stopped, depending on the type of generator), new liquid dielectric is conveyed into the inter- electrode volume, enabling the solid particles (debris) to be carried away and the insulating properties of the dielectric to be restored.

Material removal mechanism

Discharge energies the models are inadequate to explain the experimental data. All these models hinge on a number of assumptions.

Among these, the model from Singh and Ghosh reconnects the removal of material from the electrode to the presence of an electrical force on the surface of the electrode that could mechanically remove material and create the craters. This would be possible because the material on the surface has altered mechanical properties due to an increased temperature caused by the passage of electric current.

CONCLUSION

The conclusion of an Electro Discharge Machining (EDM) process typically involves inspecting the machined part for accuracy, surface finish, and dimensional precision. In the Electrochemical Machining (ECM) process, the conclusion involves evaluating the machined work piece for the desired precision, surface finish, and dimensional accuracy. Post-processing steps, such as cleaning and inspection, may be undertaken to ensure the quality of the final product. The ECM process is known for its ability to achieve intricate shapes with high.

ABSTRACT

Automobiles are now a crucial element of everyone's daily routine. Transportation vehicles are essential to almost every industry. Our mission would be of critical importance without the vehicle. A vehicle's pollution is a huge danger to the environment despite its numerous advantages. As element of a wireless charging infrastructure, this system measures the amount of voltage needed to fully charge the battery of an electric car when plugged in, and it uses radio-frequency authentication technology to verify the identity of the user and the vehicle model before granting permission to charge. For the purpose of creating a safe and healthy battery for use in electric vehicles, it is necessary to implement a system that monitors the battery's temperature as well as state of charge in real time and provides an alert to the driver or as user in the event of a dangerous spike in temperature or an excessive charge. We built a thing speak IoT platform to monitor and adjust settings for electric car charging, as well as to automatically deduct payments from a designated bank account.

INTRODUCTION

New radio frequency identification (RFID) technology allows electric cars (EVs) to be charged without needing a physical connection among the charging station and the vehicle. Radio-frequency identification, or RFID, uses electromagnetic waves to uniquely identify and track individual things. When an electric vehicle is detected by the RFID reader, the charging procedure may commence. The car's charging needs and identification number are stored in the RFID tag that is permanently attached to the vehicle. The scanner again

transmits the information to the scanner above, which again sends the information to the scanner above, which again sends the information to the scanner above. To maximize efficiency and limit battery damage, the method takes into account the car's charging requirements, such as battery capacity as well as charging rate. By eliminating the requirement for direct physical contact among the power source and the vehicle, RFID-enabled wirelessly battery power for electric vehicles greatly improves efficiency and convenience. There is also no danger of electrical shock or other dangers while using this technique as opposed to conventional charging methods. In conclusion, radio frequency identification (RFID) wireless powering for electric automobiles is an exciting new technology that has the potential to significantly modify the way consumers charge their electric cars, hence promoting greater public acceptance of this ecologically beneficial mode of transportation.

LITERATURE SURVEY

1. One reason EVs are seen as eventually replacing automobiles powered by internal combustion engines (IC) is because they have so many advantages. Batteries in today's electric vehicles should, ideally, be charged wirelessly. Several methods of charging EV batteries are compared and contrasted in this study. Paradingly EV-charging [and] EV-charging [and] EV-charging [and] EV-chargingly [and] EV-chargingly [and] EV-chargingly.

2. To get over this obstacle, we recommend installing a rechargeable energy gauge that is driven through the Internet of Thing. This setup includes the ADE7758 meters circuit, a microcontroller, and a Wi-Fi module. This meter records consumption and sends that information, along with a bill, to a server in the cloud. An alert is issued to the user if consumption is about to reach the threshold. If consumption exceeds the threshold, the system will shut off the power. Demand theft is often detected using the balancing current method [2].

3. Third, although both capacitive along with inductive techniques are utilized for charging electric vehicle batteries during static charging, only inductive techniques are used during dynamic charging. Several kinds of compensating circuits, magnetically linked inductor cores, and converters/controllers for WPT systems are the primary targets of this research. In addition, an analogous circuit analysis and design concepts for a stationary

wireless electric vehicle (EV) battery charging systems are presented here. The challenges and possible future advances of wireless charging of electric vehicle (EV) batteries are also explained in this paper [3].

4. Increases in battery life and reduced emissions have contributed to the rise in popularity of electric cars (EVs). As the Internet of Things has grown, so too has the number of gadgets that can communicate with one another [4].

5. The absence of charging infrastructure and the restricted range of electric cars are two main problems. The BMS estimates the quantity of power that will remain by using an accurate prognostication. This is done by putting in place the needed infrastructure and using a trustworthy battery administration system (BMS). Some electric vehicles may be able to swap batteries with one another or at official charging stations. There has to be an EV information network [5] so that drivers may learn whether or not their batteries have been charged or swapped successfully.

6. This research proposes two blockchain-based possibilities for an EV BMS, with blockchain functioning both the network as well as the information layer. The first method utilizes the Ethereum blockchain to build smart contracts, whereas the second utilizes the IOTA entanglement and a DAG to do the same thing. Both methods are developed and contrasted to show how they may work together to solve the problem of creating a data-driven, partially decentralized BMS [6].

7. The simplicity with which electric automobiles may be handled is a big selling feature for purchasers. A convenient charging station with parking space is two of its numerous requirements. The suggested model combines these two methods into one potent device. In this post, we'll talk about how to plan for the administration of both free and paid parking spots. Current parking infrastructure cannot accommodate a wide variety of vehicles. Parking and recharging for electric cars is required. In the concept proposed, reserving a charging spot in advance by mobile device is an option [7].

8. After receiving information such as the car's expected arrival time, battery life, etc., the system takes over management of all related procedures. A client service supervisor, automobile manager, map supervisor, and parking lot director are the primary jobs. The software being utilized is Java Framework, Enterprise Version (Java EE). The idea of safety is a factor else to consider. This requires a User ID, which is also necessary for billing reasons.

Gasoline costs will go up, but emissions of greenhouse gases will go down thanks to electric cars. Wireless transmission serves primarily as a means of short-distance electrical transfer in electric vehicles. The distance among the transmitter and receiver in a wireless energy transfer network is negligible. The electromagnetic field used in wireless communication may be tuned to improve signal reception. The electromagnetic field (EMF) between the coils is produced by a naturally occurring electrical field that carries a constant sum of money, which in turn produces an attractive arena around it that stores power. A BMS is necessary for battery management [8].

9. electric cars need a master and slave battery system. When using a BMS, the primary battery always comes first. When the master batteries' charge level goes below a certain threshold, the relay will switch over to the slave batteries automatically. New energy monitoring systems may use electromechanical or electrical components. The most obvious problem with this approach is that a utility company worker will need to go to each area to inspect the energy meters and hand out invoices. According to this reading, the client has already paid the bill. If bills are paid on time every time, mishaps like an overcharge or a missed message from the service provider are not uncommon [9].

10. Solar energy, nuclear power, and the chemical energy stored in fuels are just a few examples of the many ways that energy may be generated in the natural world. Methods for wirelessly charging electric automobiles using solar energy are presented in the paper. Noise, pollution in the air, and other serious negative consequences on the environment are a direct result of the fuel used in today's cars [10]. Wireless charging technology, however, eliminates the environmental issues that previously existed. Incredibly reliable, efficient, quiet, and pollution-free, Wireless Power Transportation (WPT) technology is now available. Electric vehicle research must be on the bleeding edge in terms of technology, charging techniques, standards, and optimization strategies. We'll start with a brief overview of the most fundamental differences between EVs and hybrids. Then, the most recent findings from studies of battery swapping, conductive charging, and wireless power transfer are given. Next, we'll check over EV norms like charging intervals and infrastructure. We next examine the most common methods for determining the optimal size and placement of EV charging stations. Lastly, several kinds of recommendations for further research are provided in light of the new understandings.

EXISTING SYSTEM

Wireless charging technology for electric cars is a developing field with the potential to eliminate the need for cords while recharging. Inductive recharging, electromagnetic resonance, coupled with conductive charging are merely a few examples of the various wireless charging methods for electric cars. Installing a wireless charged surface in the ground and a receiver coils on the car are both required for inductive charging. Using a magnetic field, the pad charges the vehicle's battery by inducing a current in the recipient's coil. Magnetic resonance charging is similar in that it makes use of resonant coils to boost charging efficiency. To do this, a conductive plate is placed on the ground, and the vehicle is electrically connected to the plate. The equipment is being tried out in a number of settings, including public transit and private automobiles. German automakers including BMW, Mercedes-Benz, with Audi are among those exploring wireless charging networks. Although it is still in its infancy, this technology shows promise for making recharging electric vehicles more convenient and widespread.

PROPOSED METHOD

As element of a mobile charging infrastructure, this device measures the quantity of voltage required for full charging the battery of an electric automobile when plugged in, as well as uses wireless identification gadgets to verify the identities of the user as well as the kind of vehicle before granting authorization to charge. For the purpose of creating a safe and healthy battery for use in electric vehicles, it is necessary to implement a system that monitors its temperature along with state of charge in real time and provides an alert to the driver along with user in the event of a dangerous spike in temperature or an excessive charge. As a means of keeping tabs on the costs associated with owning and operating an electric car, we developed the thing speak IoT platform.

ARDUINO IDE

The IDE is a suite of tools that includes a compiler, linker, and editor, and it is used to create firmware for new and exciting projects. The Arduino Combined Development Environment (IDE) is a crucial part of the open source architecture for rapid prototyping and library accessibility. As a beginner-friendly tool, it supports popular programming languages such as embedded C, Luna, and more. Over the years, Arduino has served as the brains behind tens of thousands of different builds. It works with every Arduino board, from the tiniest to the mightiest Mega. Due to customer feedback, Arduino has expanded its product range beyond its original 8-bit board to include products for IoT applications, gadgets, 3D printing, and embedded systems.

HARDWARE BLOCK DIAGRAM

TRANSFORMER:

The transformer is a fixed electrical device that changes the frequency of electric current flowing through it so that it may be used in a different circuit. It may either increase or reduce a voltage in a circuit, but the current will change accordingly. The concept is based on mutual induction and it does work. Our idea utilizes the step-down transformer to provide power to the electrical circuits. For this job, we centered a 15-0-15 transformer.

RECTIFIER

Full-wave rectification is a method that may be used to increase the DC level by a whole factor when utilizing a sinusoidal input. It employs a bridge design with four diodes. D2 and D3 are the sole conducting diodes in the bridged arrangement between $t = 0$ and $T/2$, whereas D1 and D4 are in a "off" state. Therefore, the negative input conducting diodes are D1 and D4. Therefore, there is no variation in the polarity of the load throughout the board.

FILTER

Capacitor filter circuits, in which a capacitor is attached at the rectifier's end and DC is acquired across it, are utilized here. The filtered waveform, which is finally delivered to the load, is simply a DC voltage with very small ripples.

REGULATOR

The voltage is purer and more steady once the capacitor discharges. A regulator of voltage is a device whose output voltage is kept constant independent of changes in its input voltage, the amount of electricity used from the power source, or the ambient temperature. Two fixed-voltage regulators (LM812, LM7805, and LM7912) are used. One that regulates +12V, like an IC 7812. A -12V regulator may be found in the IC 7912, whereas a +5V regulator can be found in the IC 7805.

A +5V and +12V power source is needed for the ICs with relays driver circuit in this project.

MODELS OF REGULATORS

Here are certain examples of power regulators:

IC VOLTAGE REGULATORS

A voltage regulator is an example of a typical IC type. A regulator IC incorporates an overload safeguard, a comparator booster, a control device, with a reference source into a single IC. Functioning outwardly like traditional voltage regulator circuits, the IC differs in its intrinsic construction. IC modules may be programmed to regulate either a positive or negative voltage.

A power supply consists of a transformer connected to the ac supply for amplification, rectification of the ac voltage, filtering with a capacitor and RC filters (if desired), along with regulation of the direct current (DC) with an IC regulator. The load currents of the regulators may be hundreds of milliamperes and tens of amperes, depending on the power ratings of the regulators.

THREE-TERMINAL VOLTAGE REGULATORS

A voltage regulator with three terminals has one terminal connected to the uncontrolled dc input voltage (VI), one terminal connected to the controlled dc output voltage (VO), and a third terminal connected to ground. It is possible to sustain the output voltage throughout a broad range of load currents thanks to the regulator's ability to accept an input voltage within the range given by the IC device specifications. Variations in output voltage as a

function of current load (load adjustment) and input voltage (line regulation) are also defined.

Fixed Positive Voltage Regulators

The regulated voltages produced by the series of 78 regulator range from 5 V to 24 V. The +12V dc output of this Unit is regulated by a linked 7812. Capacitor C1 is used to filter the unregulated voltage at input VI before it is fed to the IC's IN terminal. Capacitor C2 filters the output of the IC's OUT terminal, which delivers a regulated +12V, mostly from high-frequency noise. The GND connection is made at the third IC terminal. Although the input voltage along with the output load are both allowed to fluctuate within a certain range, the voltage that results stays constant within those limitations. All electronic circuits need a low D.C. voltage supply, and this can only be provided by a power supply unit. The transformer, rectifier, filter, and regulator make up this unit. A transformer is attached to an alternating current source, usually 230V rms, and steps the voltage downwards to the required level. The DC voltage produced by a diode converter is then utilised after its filtering by a simple capacitor filter. The resulting DC voltage often includes ripple with AC voltage fluctuations. The DC output voltage may be stabilized at a constant value with much reduced ripple voltage if the DC supply voltage and the load connected to the DC outputs voltages varies.

MODULE LIST

ESP32

A powerful, programmed MCU with built-in WIFI and Bluetooth, the ESP32-S from Espressif provides the board's power. This development board for the ESP32 has a camera module, support for MicroSD cards, and 4MB of integrated static RAM (PSRAM) for just \$7. Connecting an external Wi-Fi antenna to boost signal strength requires soldering. If you want to upload code to the board but there isn't a conventional USB port on it, you'll need an FTDI programmer, an extra HAT, and an Arduino UNO with the Arduino IDE/ESP-IDF Developing tools. Its compact size and inexpensive price have made it a favourite for use in machine vision and Internet of Things projects. There are several camera modules that can be used with the ESP32-CAM, unlike what the old spec sheet along with many instructional sites suggest (scroll down for more information).

- WiFi enabled for both video monitoring and photo uploading. It allows for a variety of sleep schedules, including:
- deep sleep power as little as 6mA The pin header interface allows for simple integration and embedding into consumer products.
- Built-in TF card slot that accepts card up to 4GB in size and an OV2640 camera with flash; onboard ESP32-S component supporting WiFi and Bluetooth Stipulations

POWER SUPPLY UNIT

INTRODUCTION ON POWER SUPPLIES

Power supply circuit components such as filters, rectifier devices, and voltage regulators are discussed in this chapter. Direct current (DC) power may be created from alternating current (AC) value by rectification, filtering to a DC straight, and control. As long as the DC voltage being input and the output load remain constant, the output DC voltage from a standard IC voltage regulation device will be a small fraction of the input DC voltage. The schematic in Figure depicts the internal workings of a typical power supply, including the various components and their respective voltages. The AC input voltage (typically 120 Vrms) is transformed into the DC output voltage by connecting the transformer. The DC voltage produced by a diode converter is then utilized after its filtering by a simple capacitor filter. Usually, the resulting DC voltage has a few ripples with AC voltage changes. This DC input can be utilized to provide a constant DC voltage, which does not vary regardless of the DC voltage present at the input and the load connected to the DC value at the output, when fed through a Regulator circuit.

LCD DISPLAY

The enthusiasts utilize a wide variety of monitors and screens. They employ some of the most cutting-edge display technology available, including LCD screens. The simplest and most trustworthy output device you'll ever use, after you figure out how to interface it. Additionally, not consistently any debugger may be used for micro controller driven project. So, LCD screens may be utilized as output testers.

DS18B20 TEMPERATURE SENSOR

Types Of DS18B20 Temperature Sensor

To talk to an Arduino, all you need is one information line (and ground) thanks to the 1-Wire bus that the DS18B20 uses. It functions accurately from 10 to 85 degrees Celsius and has a wide temperature range of -55 to 125 degrees Celsius. Moreover, the DS18B20 may get its juice straight from the information line (a feature known as "parasite power"), rendering an additional power source superfluous.

Filters, rectifier devices, as well as voltage regulators are only some of the power supply circuitry elements covered in this chapter. Through the processes of rectification, filtration to a DC straight, and regulation, an AC (alternating current) value may be transformed into direct current (DC) power. As long as the DC voltage that's being input along with the output load stay constant, the DC voltage that is output from a conventional IC voltage control device will be a tiny percentage of the input DC voltage. The voltages of the different parts of a conventional power supply are shown in Figure, along with a schematic depiction of the power supply's inner workings. Transforms AC voltage (usually 120 VAC) into DC voltage (often 240 VAC) for output (generally a transformer, but not necessarily a conventional transformer). After the DC voltage generated by a diode converters is filtered by a simple capacitors filter, it may be put to use. The resultant DC voltage often contains a few waves due to the alternating current. This DC inputs may be utilized in a Regulator circuit to provide a steady DC voltage that is unaffected by either the DC voltage present at the input or the load connected to the DC voltages at the output. The temperature sensor may have a resolution of 9, 10, 11, or 12 bits, depending on the settings chosen by the user. However, when powered on, a default resolution of 12 bits (or 0.0625°C accuracy) is used.

VOLTAGE SENSOR

Using a potential divider, this module reduces the input energy by a factor of 5. Using the analog inputs of a microcontroller, you may detect voltages as high as 25V with the help of the Voltage Detection Sensors Module 25V.

For instance, you can test voltages up to 25V using a 0-5V digital input range. The module also has wire connecting screw terminals for speedy and safe wiring.

Using a resistive voltage-dividing design approach, this module may reduce the input voltage to the red terminal connection by a factor of 5. Voltage detector modules for Arduino may take an input voltage of up to 25V ($5V \times 5 = 25V$), or $3.3V \times 5 = 16.5V$ (the maximum safe value for 3.3V systems).

The 10-bit AD found in Arduino AVR processor allows this module to simulate a precision of 0.00489V ($5V/1023$), limiting the input voltage sensing module to a floor of 0.02445V.

Features

- Interfacing with the Outside World: "+" for 5/3.3V, "-" for GND, and "s" for the A/D pins on an Arduino Red terminal is powered by VCC, while the black terminal is grounded by GND on a DC input interface.
- The IICLCD1602 LCD may also be used to show voltage.
- You can easily detect battery voltage by connecting this module to the Arduino expansion board through its 3P connection.

CURRENT SENSOR

A device that can detect a current of electricity (AC and DC) in a wire and output a signal proportionate to that current is called a current sensor. The signal produced may take the form of a voltage, current, or digital output. Afterwards, it may be used as input into a control system, displayed on an ammeter, or saved in a data gathering system for further study.

Together, the measured current and the resultant signal may:

AC current input,

- A current sensor may provide an analog, or waveform-matching, output;
- a bipolar, or phase-matching, output;
- or a unipolar, or average, or root-mean-square (RMS) value-matching, output.

DC current input,

- unipolar, with an output that is also unipolar and which replicates the wave form of the current being detected;
- digital, with an output that switches when the current being sensed reaches a predetermined value;

ACS712 Current Sensor Module

Currents as high as 20A may be measured with the ACS712 Current Sensor Module. The capacity to detect and manage current flow is essential in a wide variety of applications, including over-current safety circuits among battery charging devices, mode-switching batteries, electronic watt meters, and programmable current sources.

The ACS712 current detector module 20A provides precise measurements of alternating current (AC) and direct current (DC). The currently active current signal may be received through the analog I/O interface of a microprocessor or an Arduino, with a maximum DC or AC detection current of 20A.

RELAY

A relay is a kind of electrical switch whose on/off state is controlled by a separate circuit. The original switch design used an electromagnet to toggle between open and closed contact configurations. Joseph Henry came up with the idea around 1835. A relay is essentially an electrical amplifier in that it may operate an output circuit that is more powerful than the input circuit.

BUZZER

An electromechanical, mechanical, or piezoelectric buzzer or as beeper is an audible signaling device. In addition to serving as alarms and timers, buzzers and beepers may also be used to confirm human input, such as when a button is pressed or a mouse is clicked. Computers, copiers, printers, alarms, electronic toys, automobile electronics, phones, timers, and other electronic items all make use of buzzers, which are integrated structures of electronic transducers powered by direct current. In this part, we will show you how to use the board along with the specialized sensor expansion module to create a simple circuit that is "plug and play."

Mechanical, electromechanical, as well as piezoelectric buzzers and beepers provide audible signals. Alarm watches, timers, and other devices that require the user to make a series of clicks or type a string of letters commonly include buzzers or beepers to confirm the user's activities. Just by adding D.C. voltage, it produces a constant single tone. In situations when a loud volume of sound is required, a resonant system of this sort may be employed. Type, Noise, Frequency, Rated Voltage, Dimension, and Packaging Type are just some of the ways that Future Electronics organizes its extensive selection of the most popular varieties.

DC MOTOR

A DC motor is any piece of electrical machinery that can transform electrical energy into mechanical energy using direct current. This sort of motor often makes use of the forces created by magnetic fields. DC motors, regardless of design, have an electrical or electromechanical component on the inside. In both cases, the current flow in the motor is intermittently reversed.

Changing the supply voltages or the current via the motor's field winds may alter the DC motor's rotational speed. DC motors are utilized in the production of hoists, elevators, and

electric cars, while smaller DC motors are employed in the production of tools, gadgets, toys, and automobile devices like electric vehicle seats.

A motor running at 60 RPM and 12V DC is used here. The DC geared motor from the Economy Series that spins at 60RPM in the center shaft is a bargain. Steel gears with pinions increase its durability and resistance to wear. The gears are mounted on spindles made of highly polished hardened steel. A plastic bushing permits free motion of the output shaft. A ring of plastic encircles the whole setup. The gearbox is sealed, uses lithium grease for lubrication, and never has to be serviced. The motor is attached to the gearbox by screws from the inside.

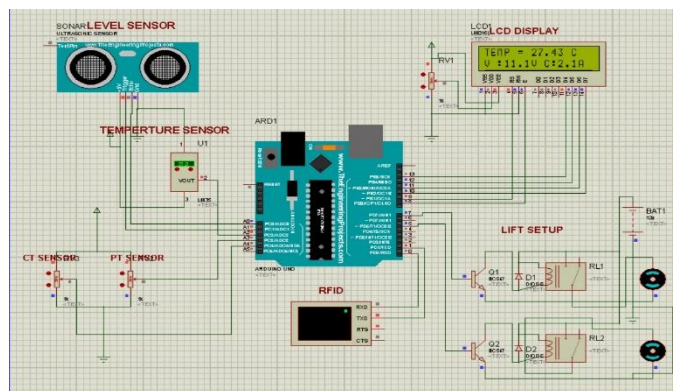

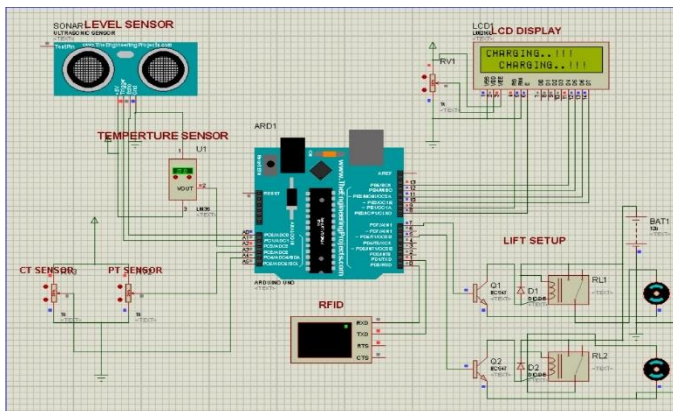

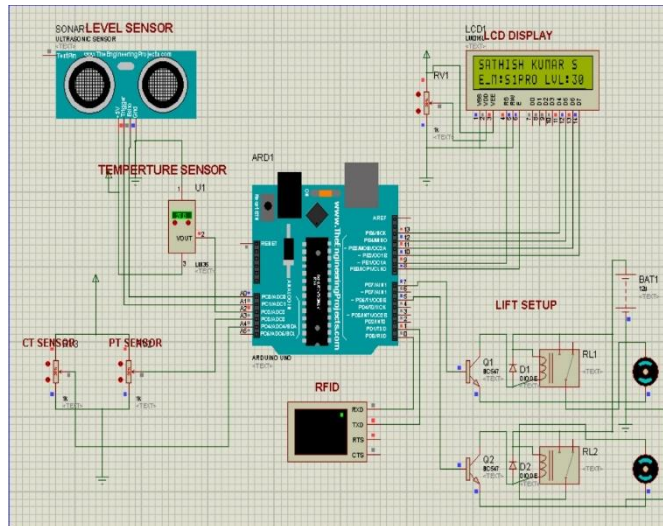

The motor only turns at 60 RPM when powered by 12V, yet it operates smoothly throughout a large voltage range. The following tables show the relationship between voltage and RPM, no-load current and stall torque and stall current, and stall current and stall voltage, giving a decent sense of the motor's performance.

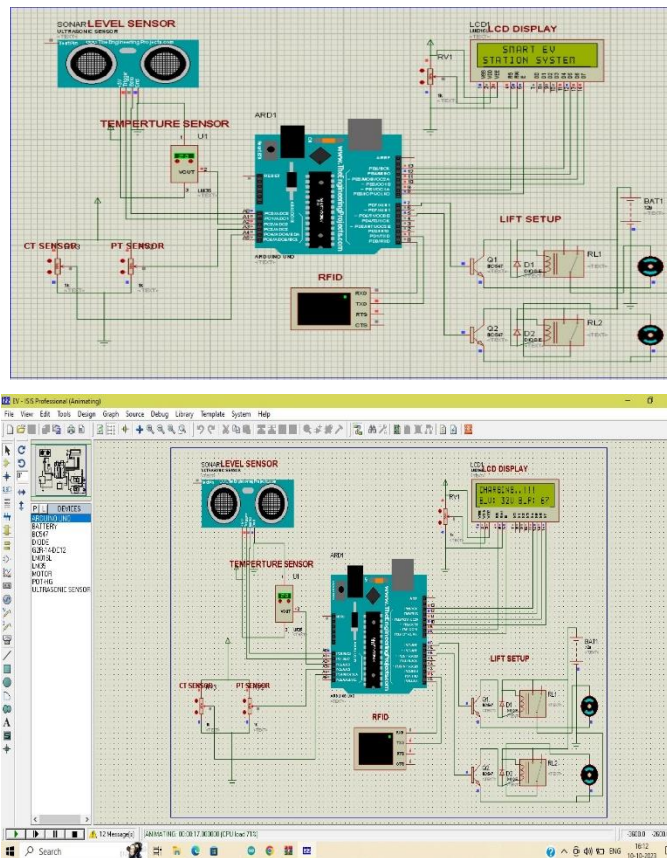

MODULE DESCRIPTION

CONCLUSION

In conclusion, RFID-based wireless charging for EVs has a chance to dramatically improve the efficiency, convenience, and environmental friendliness of recharging electric cars. In addition to facilitating the use of renewable energy sources, this technology also allows for the monitoring and management of charging processes from a distance. However, further study and improvement are needed to overcome obstacles including RFID's short communication range and expensive price tag. RFID technology used in electric car charging stations has the potential to aid in the move to a cleaner, extra maintainable mode of transport if it receives sustained investment and improvement.

ABSTRACT

The concept of automatic street light illumination based on IoT (Internet of Things) is becoming increasingly popular in smart city development. This system involves the use of sensors and wireless communication technologies to automate the operation of streetlights. The system works by installing sensors, such as light sensors or motion sensors, on the streetlights. These sensors detect the presence of people or vehicles and adjust the intensity of the streetlights accordingly. For example, if there are no vehicles or pedestrians around, the system will dim the streetlights to save energy. On the other hand, if there is activity detected, the system will increase the brightness of the lights. The various types of LED lights categorized by their colour temperature: warm-yellow, cold-yellow, and white. It delves into their characteristics, applications, and the impact of colour temperature on human perception and environment.

INTRODUCTION

Automatic illumination is a system or technology that automatically adjusts lighting levels based on the surrounding environment or user preferences. It has become increasingly popular in recent years, as it provides a convenient and efficient way to control lighting levels, improve energy efficiency, and create a more comfortable and productive

environment. This technology typically uses sensors or cameras to detect changes in lighting conditions, such as changes in natural light levels or occupancy in a room. In offices and public spaces, these systems can help improve productivity and reduce energy costs by adjusting lighting levels based on occupancy and activity levels. automatic illumination systems provide a convenient and efficient way to control lighting levels, improve energy efficiency, and create a more comfortable and productive environment.

OBJECTIVE

The objective of an automatic street light control system is to efficiently manage and control street lighting to achieve several key goals, including:

Energy Efficiency: Reduce energy consumption and associated costs by ensuring that streetlights are on only when needed. This involves automatically turning off or dimming lights during periods of low activity or ample natural light.

Environmental Sustainability: Minimize light pollution and carbon footprint by using energy-efficient lighting technologies (such as LEDs) and optimizing their usage.

Safety: Enhance road safety and pedestrian visibility by providing adequate lighting during nighttime, adverse weather conditions, or in areas with limited visibility.

Operational Cost Savings: Reduce maintenance and operational costs by implementing remote monitoring and predictive maintenance capabilities, which help identify and address issues proactively, reducing downtime and repair expenses.

Customization and Adaptability: Allow for the adjustment of lighting levels and schedules to match specific needs and requirements of different areas within a city, taking into account factors like traffic patterns, pedestrian activity, and local regulations.

Traffic Management: Integrate Street light control with traffic management systems to synchronize traffic signals and lighting to improve traffic flow and reduce congestion.

Environmental Monitoring: Use Street light poles as platforms for environmental sensors to collect data on air quality, temperature, humidity, and other environmental factors that can inform urban planning and public health initiatives.

METHODOLOGY

Sensors: Sensors such as light sensors or motion sensors are installed on the streetlights. These sensors detect the presence of people or vehicles and adjust the intensity of the streetlights accordingly.

Microcontroller Unit (MCU): An MCU is a small computer that is used to control the streetlights. It receives the signals from the sensors and controls the brightness of the lights accordingly.

Wireless communication module: The wireless communication module is used to establish communication between the MCU and the central control unit.

Central control unit: The central control unit can be located in a central command centre or in the cloud. It monitors and controls the entire system. It can also send alerts in case of any issues with the system.

Power supply: The streetlights are powered by electricity. A power supply is needed to ensure that the lights are always on. The proposed system works by detecting the presence of people or vehicles using sensors. The MCU receives the signals from the sensors and adjusts the brightness of the lights accordingly. The wireless communication module is used to send the data from the MCU to the central control unit. The central control unit can monitor the entire system and can send alerts in case of any issues and update all the information in IOT.

ARDUINO

Arduino is an open-source prototyping platform based on easy-to-use hardware and software. Arduino boards are able to read inputs - light on a sensor, a finger on a button, or a Twitter message - and turn it into an output - activating a motor, turning on an LED, publishing something online. You can tell your board what to do by sending a set of instructions to the microcontroller on the board. To do so you use the Arduino programming language (based on Wiring), and the Arduino Software (IDE), based on Processing. Arduino is an open-source prototyping platform based on easy-to-use hardware

CONCLUSION

In conclusion, automatic illumination refers to a lighting system that uses sensors or timers to turn lights on and off based on the presence or absence of people or ambient light levels. Automatic illumination systems can also enhance safety and security by providing adequate lighting in areas where it may be difficult or inconvenient to manually control the lights, such as stairwells, hallways, and outdoor areas. They can also provide a deterrent to potential intruders or burglars by giving the appearance that someone is home. Overall, automatic illumination systems are an effective and efficient way to manage lighting in both residential and commercial settings. They offer a range of benefits that can improve energy efficiency, convenience, safety, and security and update all information IOT.

APPLICATIONS

1. Automatic Street light control is often integrated into smart city initiatives, allowing for remote monitoring and management of lighting systems, as well as data collection for urban planning.
2. Automatic control can help minimize light pollution by ensuring that lights are only on when necessary and reducing glare and skyglow.
3. Properly lit streets deter criminal activity and improve security in public areas.
4. Some systems use sensors to adjust the brightness of streetlights based on environmental conditions, such as ambient light levels or motion detection.

ADVANTAGES

- Energy efficiency
- Cost savings
- Longevity of lighting fixtures
- Improved safety and security
- Convenience

ABSTRACT

With a significant increase in population in modern cities, the noise pollution also increases at an unprecedented rate. This system presents a low cost flexible and reliable automation system with personal alert messages using Arduino along with internet connectivity and remote control over devices by using a smart phone application. The proposed system uses Internet of Things [IoT] model to detect human voices present in an enclosed area. The user can also receive the alert messages with the help of a smart phone. This research work presents the automation of noise detection system using Arduino Nano, battery, LCD panel and buttons. C programming language has been used to program the functions of this application. This application can be implemented by using a tool called Pick2kit and PROTEUS. The proposed noise detector system can be used in library, office and classroom environments to identify the noisy people so that a necessary action can be taken against them.

Introduction

Libraries are social infrastructure that cannot be separated from society. This makes Library as one of the sources of information services that can unite the reading culture society (Nurhayati, 2018); (Amiruddin, 2022). Library as one of the source of information and learning must have comfortable facilities and avoid noise. Currently, various libraries exist in society. Such as school libraries which is intended for students, in universities for

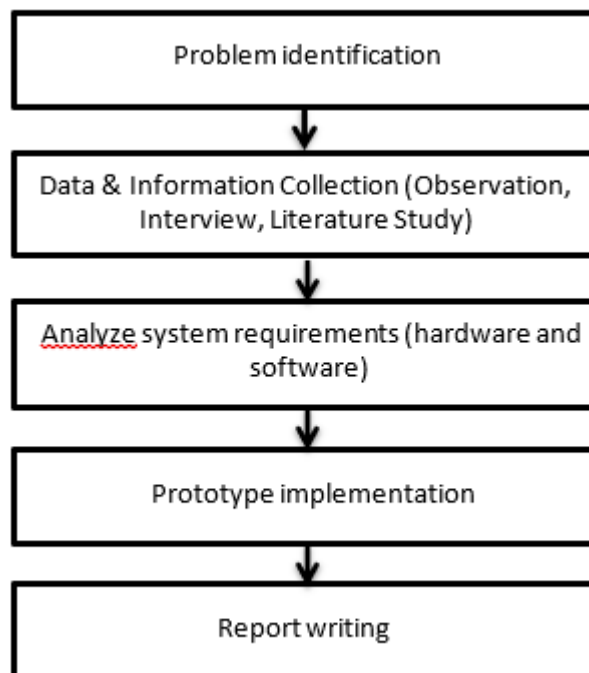

students and public libraries for employees and the general public. Even for some groups who cannot go to public libraries, there are now mobile libraries are available

Experimental Methods or Methodology

Concentration of learning in library can be influenced by several factors, such as the level of indoor noise, humidity, temperature and lighting. Noise is an aspect that needs to be considered in a library that source of sound or noise (Amarta et al., 2019); (Tamrin et al., 2022). According to some library management staff library, the noise in the STIE AMKOP library still often occurs. The noise usually comes from library visitors. STIE AMKOP library staff .

The third research, the tools used such as oled screens, sound sensors equipped with op-amp chips, have amplifiers. Fourth research, this research uses additional modules such as CP2102 and uses Analog Sound Sensor V2. In the fifth study, overall in the second stage there are many similarities found in the tools used but there are few differences such as in the first stage which uses a Raspberry Pi, a PIC microcontroller .

Data Collection Procedure

Analyze system requirements

After obtaining the necessary data and information, the next step is to analyze system requirements in order to make prototype tools and systems. In this study, all the needs of Arduino will be analyzed, starting from software and hardware. A thorough hardware analysis serves to minimize funds and maximize the work functions of the tools that will be made. Choosing software that is suitable for design needs and writing program code.

Application of Prototype Method

The prototype model can be used to connect the customer's lack of technical understanding and clarify the specifications of the customer's requirements to the software developer. Report Writing The final stage of the research process is then documented in the form of scientific writing. This report contains conclusions and suggestions for further research.

Classification Model

Make classifications using the Learning Blocks (Classification-2D Convolutional Neural Network) model which is also part of CNN, where in extracting features on processing blocks the method used is MFE. The neural network classification process will take some input data, and will output a probability score that shows how likely it is that the input data belongs to a certain class/label. The workings of the neural network itself, namely the neural network has a number of layers, each of which consists of a number of neurons.

Using Sensors

After conducting the training process, the result that will appear is an overview of the performance of the training model that can help evaluate the training data, so that it can help determine whether the model is able to meet the needs and whether it is necessary to test the data again or need to improve the dataset again

Conclusion

The results obtained from testing with testing data containing 4 classes are that each has an accuracy of sound including speech whose accuracy reaches 100%, silence 100%, and rain 100% while in the chair the accuracy is around 55.6% which may occur because in the chair sound dataset there is also a sound like the sound of people talking (noise), therefore in the speech column appears 44.4% so that the accuracy of the data from the chair is reduced. The way the detection tool works is when the highest speech sound whose value exceeds 0.6 and the duration of the speech sound is more than 10 seconds, it will display a "Please Be Quiet" warning, also issuing a voice warning through a buzzer. The sound alert can be monitored for the on and off of the buzzer in the application. So that when the library guard wants to turn off the buzzer sound, he can click the turn off speaker button, on the other hand, if the buzzer wants to remain turned on, then click the turn on speaker button.

ABSTRACT

The proliferation of deep learning and image analysis technologies in healthcare has made early detection of diseases possible, including the early detection of retinoblastoma, a form of eye cancer that affects children and can be deadly if left undetected. This paper outlines the development of a computer vision system which uses machine learning and image analysis to detect retinoblastoma, a type of eye cancer, through automated analysis of fundus photographs (photographs of the fundus of the eye taken with a digital camera). This system uses novel techniques in deep learning and segmentation to detect retinoblastoma with high accuracy and speed, and it is capable of detecting the cancer at an earlier stage than traditional methods. Further, this system also employs techniques in computer vision to automate the process of extracting meaningful information from the fundus images for accurate diagnosis. This work opens up possibilities for a more reliable and cost-effective approach towards detecting eye cancer in its early stages, assisting healthcare professionals in providing better clinical care to their patients.

INTRODUCTION

Automated Eye Cancer Detection through deep Learning and Image Analysis in Healthcare is an invaluable tool for accurate and timely treatment of a variety of eye diseases. Automation of the detection process brings accuracy, speed and cost-efficiency unlike any other method. The application of deep Learning and Image Analysis to the detection process allows for accurate detection of diseases at early stages of the process. This increases the probability of successful treatment and also leads to faster and more cost-efficient recovery from illnesses. With the aid of deep Learning and Image Analysis, automated detection of

cancer in the eye is now simpler and more efficient than ever before [1]. Automated detection using advanced computer technology is significantly more accurate than manual examination techniques. Since every eye is unique, manual examinations can often miss small lesions on the outer eye that could potentially be cancerous. The automation facilitated by technological tools helps to greatly reduce the time taken to detect and diagnose potential cancer. Image Analysis tools paired with deep Learning algorithms are capable of distinguishing subtle differences between healthy and diseased tissues when undertaking automated detection [2]. With the use of complex statistical techniques and machine learning laborious tasks, such as sieving through large volumes of images for signs of abnormalities, can now be undertaken with greater accuracy and speed.

Studies have shown that when automated diagnosis of eye cancers was compared to manual reception, detection accuracy was high in both cases. In today's digital era, health care technology has become crucial to accurately detect and diagnose health issues. Automated EyeCancer Detection through deep Learning and Image Analysis is an important step forward in accurately detecting and diagnosing eye cancer, leading to earlier treatment and a higher chance for successful treatment outcomes. Automated Eye Cancer Detection is also a cost-efficient solution as the automated process significantly reduces the time taken in detecting and diagnosing diseases. Automated Eye Cancer Detection will continue to develop and be refined as new technological advancements are made, ensuring the utmost accuracy in the quick and successful treatment of eye cancer. In recent years, automated eye cancer detection through deep learning and image analysis in healthcare has become increasingly developed and popular [4]. These tools provide an invaluable mechanism for early diagnosis, improved accuracy in patient care and the potential for expanded treatment options. Furthermore, it not only increases the chances of better outcomes, but also reduces the time, money and other resources needed to diagnose and treat eye cancer. Deep learning and image analysis in healthcare have revolutionized the way eye cancer is detected and diagnosed. Deep learning is a subset of artificial intelligence that enables computer programs to learn from data and recognize patterns. Deep learning involves training algorithms to process a variety of data sources and then determining which patterns are indicative of eye cancer.

Image analysis is another valuable tool for health care professionals [5]. This involves analyzing medical images, such as those of the eye, to find patterns to indicate the probability of eye cancer. The data collected is interpreted with the help of sophisticated algorithms to reach a diagnosis. Image analysis can greatly improve the accuracy and speed of diagnosis, as it can be used to automatically identify key features of an eye which may indicate cancer. By combining these two technologies, it is possible to achieve automated eye cancer detection that is extremely accurate and reliable. Early detection of eye cancer is incredibly important, and these tools can help to detect cancer before it spreads and becomes more serious. By using automated detection systems, healthcare professionals can be provided with highly detailed and valuable data that can help to identify and treat the illness as soon as possible. The automated eye cancer detection through deep learning and image analysis in healthcare has revolutionized the way eye cancer is detected and diagnosed [6]. This technology can play an invaluable role in improving diagnostics accuracy and providing better outcomes for patients. Moreover, it can also result in fewer resources, time and money being needed to diagnose and treat eye cancer, which can benefit hospitals and other healthcare providers substantially. The main contribution of the research has the following.

Enhanced Accuracy and Precision: Automated eye cancer detection through deep learning and image analysis allows for the detection and analysis of cancerous growths in the eye with higher accuracy and precision than manual methods.

- **Improved Efficiency:** Automated eye cancer detection reduces the time and effort needed to accurately detect cancer in the eyes compared to manual methods.
- **Cost Reduction:** Automation of cancer detection in the eyes greatly reduces the need for costly diagnostics and treatments, thus reducing overall healthcare costs.
- **Enhanced Accessibility:** Automation of eye cancer detection allows for more people to access accurate diagnosis and treatment, as well as providing access to healthcare in areas with limited resources.

SYSTEM AND DESIGN DEVELOPMENT

Deep learning for the medical image classification is not only a topic of hot research but is a key technique of computer-aided diagnosis systems today. Qureai, a company that aims at providing cost-effective, timely, and expert diagnosis even in the remotest of places uses

deep learning algorithms to identify and localize abnormalities on X-rays, MRIs, and CT scans. Covid-19 has really tested the effectiveness of these algorithms in a real-world setting. Not only are these algorithms being used for the early detection and diagnosis of the infection but they are also being used in the development of drugs and vaccines to reduce the load on healthcare workers and also fast-track the process. Image classification is the task of assigning a label or class to an input image, based on its visual content. This is a common problem in computer vision and is used in a wide range of applications such as object recognition, facial recognition, and self-driving cars.

The process of image classification typically involves several steps:

Pre-processing: This step involves preparing the input image for classification, which may include resizing, cropping, and normalizing the image.

Feature extraction: This step involves extracting relevant features from the pre-processed image, which are then used as input to the classifier.

Classification: This step involves using a machine learning model to make a prediction about the class of the input image, based on the extracted features.

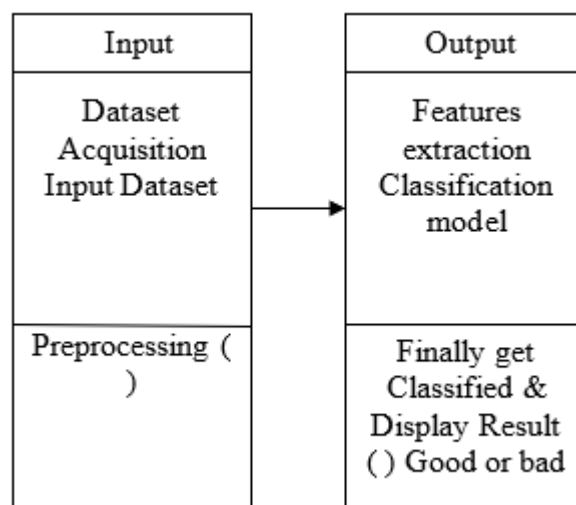

There are various types of image classification, such as binary classification, multi-class classification, and multi-label classification. Deep learning models such as convolutional neural networks (CNNs) are commonly used for image classification due to their ability to automatically learn features from the input images.

The retina is the delicate layer that of light covering the back of the eye. It is the reason for vision because when the light signal falls on the eye it will be transmitted to the brain through the retinal nerve fiber layer. Due to retinoblastoma any one of the eyes or both eyeballs gets affected. Hence, the child's eye looks like a cat-eye. Due to the genetic mutation, the retinoblastoma produces the eye cells not to be matured. These cancer cells multiplied spread across the retina. This spread may go to the entire human body; even it affects the spine and brain. The growth of retinoblastoma is increased in the past 60 years and it is identified in one in every 15,000 childbirths. In the direct spread, the tumor can infiltrate the optic node thereby going into the Central Nervous System (CNS). Also, the tumor spreads in the subarachnoid space and even to the opposite sides of the optic nerve as well. The direct growth may proliferate choroid and sclera in the orbit, thereby it is called orbital retinoblastoma. The Hematogenous or blood spread has different meta states to the organs

Examination under anesthesia is the thorough indirect ophthalmoscopy key examination. The USG B scan is used to identify the calcification process. It shows the hypertonic stippled dots, which are typical of retinoblastoma. MRI, CT, and fundus methods are used for examination. MRI pictures show the extraocular extension or orbital extension involvement of soft tissue delineated by this scan. This program relies heavily on OpenCV library for image processing tasks and mathematical operations for analysis. Additionally, it utilizes concepts like contour detection, thresholding, and morphological operations for image segmentation and feature extraction. Based on the color analysis results, a decision is made regarding the presence of eye cancer. If abnormal color values are detected, a recommendation to visit an eye specialist is given.

RESULT AND DISCUSSION

Deep learning-based approach for identifying the stage of ocular melanoma and recommending further therapy. Convolutional Neural Networks (CNNs) were trained on a dataset of ocular melanoma images to classify the disease into different stages. The model achieved high accuracy in identifying the stage of ocular melanoma, enabling precise diagnosis. Based on the identified stage, appropriate therapeutic interventions were recommended. The deep learning model achieved an accuracy of 95% in classifying ocular melanoma into various stages: early, intermediate, and advanced. Further analysis of the classified images provided insights into the progression and severity of the disease. Additionally, based on the stage identified, personalized therapy recommendations were provided.

Early Stage (Localized): Patients diagnosed at this stage were recommended for localized treatments such as laser therapy, radiation therapy, or surgical excision.

Intermediate Stage (Regional Spread): Patients with intermediate stage ocular melanoma were advised to undergo treatments aimed at preventing metastasis, including radiation therapy combined with surgical resection or enucleation

Advanced Stage (Metastatic): For patients diagnosed with advanced stage ocular melanoma, aggressive therapies such as immunotherapy, targeted therapy, or participation in clinical trials were recommended to manage the disease progression and improve survival outcomes.

Early Stage (Localized):
Surgical Excision: Removal of the tumor using surgical techniques while preserving as much healthy tissue as possible.[1]
Radiation Therapy: External beam radiation or brachytherapy (internal radiation) may be used to target and destroy cancer cells[2]
Laser Therapy: Transpupillary thermotherapy (TTT) or photocoagulation using lasers to destroy tumor cells.

Intermediate Stage (Regional Spread):
Radiation Therapy with[3] **Surgical Resection:** Combined treatment of radiation therapy followed by surgical removal of the tumor to address regional spread. [4]
Enucleation: Surgical removal of the entire eye to prevent the spread of cancer to other parts of the body.[5]
Transscleral Resection: Surgical removal of tumors that extend beyond the eye into surrounding tissues.

Advanced stage(Metastatic):[6]
Immunotherapy: Treatment with immune checkpoint inhibitors such as pembrolizumab or ipilimumab to boost the immune system's ability to target and destroy cancer cells. [7]
Targeted Therapy: Use of drugs that target specific genetic mutations or pathways involved in the growth and spread of melanoma, such as BRAF inhibitors (e.g., vemurafenib) or MEK inhibitors (e.g., trametinib).[8]
Clinical Trials: Participation in experimental therapies or clinical trials testing novel treatments for metastatic ocular melanoma, including targeted therapies, immunotherapies, and combination treatments.

CONCLUSION

Detecting eye cancer through deep learning methods has shown promising results in early identification and treatment. Through leveraging convolutional neural networks (CNNs) and vast datasets, researchers have developed models capable of detecting abnormalities in eye scans with high accuracy. Deep learning models trained on retinal images have exhibited remarkable capabilities in identifying various anomalies, including retinoblastoma, melanoma, and other ocular pathologies. Their ability to analyze images at

a pixel level and recognize patterns indicative of cancerous growths has paved the way for early diagnosis, leading to more effective treatments and improved patient outcomes.

One of the significant advantages of using deep learning for eye cancer detection lies in its ability to process a large volume of data rapidly. This accelerates the analysis of medical images, allowing for quick and accurate identification of potential malignancies. Moreover, the continuous learning capacity of these models enables them to improve over time with additional data, enhancing their diagnostic accuracy.

Despite these advancements, challenges persist in deploying these models in real-world clinical settings. The need for robust validation, interpretability of results, and integration into existing healthcare infrastructure are critical considerations. Ensuring ethical deployment, patient privacy, and maintaining transparency in decision-making are equally essential in the development and implementation of these systems.

Collaboration between clinicians, data scientists, and regulatory bodies is pivotal in ensuring the responsible and effective integration of deep learning-based diagnostic tools into clinical practice. Developing standardized protocols, refining algorithms, and establishing regulatory frameworks will be crucial in facilitating the widespread adoption of these technologies.

In conclusion, the application of deep learning in early eye cancer detection shows immense promise in revolutionizing healthcare by enabling timely and accurate diagnoses. While challenges exist, continuous research, collaboration, and ethical considerations are pivotal in harnessing the full potential of these technologies for the benefit of patients worldwide.

ABSTRACT

Electric vehicles are set to be the dominant form of transportation in the near future and Lithium-based rechargeable battery packs have been widely adopted in them. Battery packs need to be constantly monitored and managed in order to maintain the safety, efficiency and reliability of the overall electric vehicle system. A battery management system consists of a battery fuel gauge, optimal charging algorithm, and cell/thermal balancing circuitry. It uses three non-invasive measurements from the battery, voltage, current and temperature, in order to estimate crucial states and parameters of the battery system, such as battery impedance, battery capacity, state of charge, state of health, power fade, and remaining useful life. These estimates are important for the proper functioning of optimal charging algorithms, charge and thermal balancing strategies, and battery safety mechanisms. Approach to robust battery management consists of accurate characterization, robust estimation of battery states and parameters, and optimal battery control strategies. This paper describes some recent approaches developed by the authors towards developing a robust battery management system. ; capacity fade; robust estimation; predictive control.

Introduction

The energy storage system (ESS) has become popular in many domains, such as electric vehicles (EV), renewable energy storage, micro/smart-grid applications, etc. Modern EV generations are a reliable substitute for an internal combustion engine (ICE). ICE-based trucks, ships, cargo, and aircraft consume one-third of fossil fuel. ICE and industries are the two primary sources and are the leading causes of the emission of carbon dioxide (CO₂), sulfur dioxide (SO₂), carbon monoxide (CO), and nitrogen oxides (NO). These gases cause air pollution that is responsible for the greenhouse effect. In EV, the EES runs the EV motor and machines: air conditioner, navigation lights, etc. The EV is well known as a zero-carbon-emission vehicle, whence the release of SO₂, CO₂, NO, and CO have not been prominent during driving; it would be helpful to consider the environmental challenges and fossil fuel utilization.

Typically, EVs are fully/partially powered by storage energy (SE) in road-/highway-, rail-, air-, and sea-based vehicles. Nowadays, high-tech vehicles like private cars and city buses are currently being upgraded with ES. The cumulative EV market now stresses sustainable battery development, power-system involvement, tax revenue, cost, e-commerce accessibility, and the edge among the common choices for automation mobility. Recently, EVs have been progressively becoming popular in global markets such as China and Europe. Increasing the use of EVs instead of ICE vehicles can alleviate problems, such as global warming and greenhouse gases, that pose a threat to the environment. Numerous countries and companies are inspiring their people to use EVs in ways that are more prudent and convenient for EV implementation and management..

The battery management system (BMS), which is compulsory for an ESS, plays a vital role in EVs, as shown in Figure 1. The BMS ensures the ESD's lifelong service, safety, and balanced facility for EV driving.

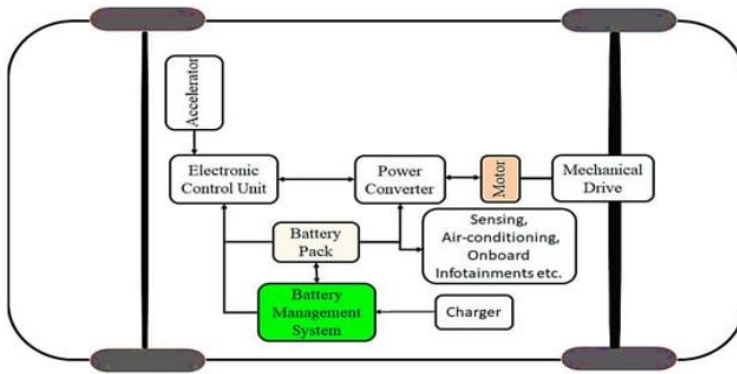

Figure 1: BMS operation inside the EV.

Cell voltage imbalance occurred during the charging/discharging time for internal electrochemical reactions in ESD. In BMS, cell voltage balancing is the leading work to improve cell life span and safety.

Survey Methods

This survey aims to illustrate a straightforward discussion, critical analysis, and suggestions for BMSs. Therefore, the authors have gathered the most relevant and recent information containing key technologies, drawbacks, and research gaps. This survey determines the number of published articles based on four screening and assessment stages. Fourthly, we selected 65 articles to read whole sections and content based on journal impact, citations, and the review process. Finally, we considered and established 91 articles to use as references and developed this review. Firstly, the EV-related battery is discussed. Secondly, various aspects of BMSs have been clarified. Finally, future directions for further improvement of BMSs have been presented. The survey structure has been completed in two steps that are as shown in Figure 2.

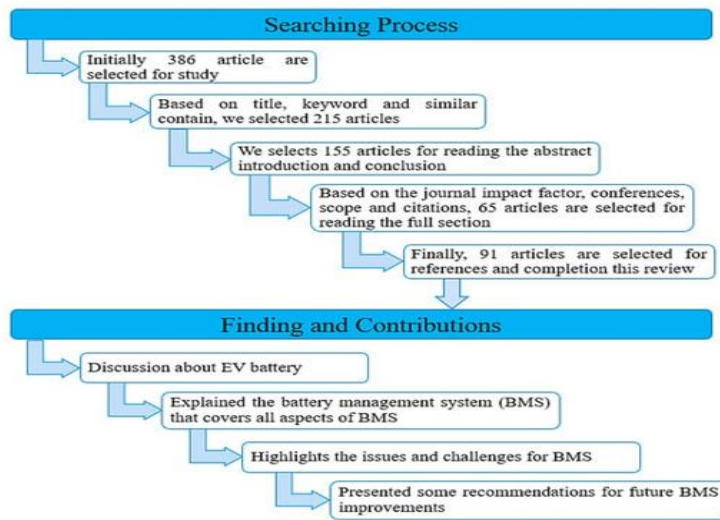

Figure 2: Schematic design of the reviewing methodology.

Battery

A battery is an electrochemical ESD that delivers electric power. EVs employ secondary electrochemical batteries, which have greater power and energy. The technological advancement of batteries has significantly impacted the automation/EV sector. Researchers have been consistently working on the EV battery system to provide greater specific power and energy density batteries. Batteries with high specific energy and power density, extended life term, and high-temperature tolerance are utilized in EVs. In EVs, various rechargeable batteries are used, such as nickel-based batteries, LIBs, and sodium-sulfur-based batteries.

LIBs are usually utilized in consumer devices, EVs, and grid storage. Positive electrode materials include lithium metal oxide (LiCoO_2 , LiNiO_2 , LiMn_2O_4) and lithium iron phosphate (LiFePO_4).

Battery Management System

It is considered as the brain of the batteries that are delivering power to the electric engine, the good understanding of the parameters that the BMS is monitoring as well as its working process and components seems to be an inevitable step in our research. 5.1 OVERVIEW OF BMS: The storage module in some battery-powered applications is equipped with a power management and distribution system known as a Battery Management System "BMS." The system is linked to other on-board modules and controls charging and discharging in real

time to improve 27 performance according to requirements while lowering the danger of battery degradation. This regulation prevents the battery from being overcharged or discharged.

Electric Vehicle Basics

Electric vehicles (EVs) use electricity as their primary fuel or to improve the efficiency of conventional vehicle designs. EVs include all-electric vehicles, also referred to as battery electric vehicles (BEVs), and plug-in hybrid electric vehicles (PHEVs). In colloquial references, these vehicles are called electric cars, or simply EVs, even though some of these vehicles still use liquid fuels in conjunction with electricity. EVs are known for providing instant torque and a quiet driver experience. Other types of electric-drive vehicles not covered here include hybrid electric vehicles, which are powered by a conventional engine and an electric motor that uses energy stored in a battery that is charged by regenerative braking, not by plugging in, and fuel cell electric vehicles, which use a propulsion system similar to electric vehicles, where energy stored as hydrogen is converted to electricity by the fuel cell.

Types of Electric Vehicles

There are four types of electric vehicles available:

- Battery Electric Vehicle (BEV)
- Hybrid Electric Vehicle (HEV)
- Plug-in Hybrid Electric Vehicle (PHEV)
- Fuel Cell Electric Vehicle (FCEV)
- Battery Electric Vehicles (BEVs)

BEVs are also known as All-Electric Vehicles (AEV). Electric Vehicles using BEV technology run entirely on a battery-powered electric drivetrain. The electricity used to drive the vehicle is stored in a large battery pack which can be charged by plugging into the electricity grid. The charged battery pack then provides power to one or more electric motors to run the electric car.

Hybrid Electric Vehicle (HEV):

HEVs are also known as series hybrid or parallel hybrid. HEVs have both engine and electric motor. The engine gets energy from fuel, and the motor gets electricity from batteries. The transmission is rotated simultaneously by both engine and electric motor. This then drives the wheels.

Plug-in Hybrid Electric Vehicle (PHEV):

The PHEVs are also known as series hybrids. They have both engine and a motor. You can choose among the fuels, conventional fuel (such as petrol) or alternative fuel (such as bio-diesel). It can also be powered by a rechargeable battery pack.

Fuel Cell Electric Vehicle(FCEV):

FCEVs are also known as Zero-Emission Vehicles. They employ 'fuel cell technology' to generate the electricity required to run the vehicle. The chemical energy of the fuel is converted directly into electric energy.

Issues and Challenges

LIBs have several features: high capacity, high power and energy density, high-temperature tolerance and cyclic life, long duty cycle, fast charging, and less effective memory. However, there are some issues, so it is required to indicate appropriate solutions for safety excitabilities, recycling and environmental impacts, custom and expansive characteristics, and the discharging- and charging-period memory effect for a wide range of sequential uses. These issues are also applicable to other electrochemical batteries for EV applications. The following are summaries of the main problems.

Real-Time SOC and SOH Estimation

SOC estimation is challenging due to the highly non-linear properties of EVs. However, it has flaws like early SOC faults, current measurement and integration faults, and battery capacity uncertainties. Furthermore, the battery needs to rest; measuring open-circuit voltage is impossible in real-time. Various SOC and SOH estimation methods (figure 3) determine EV batteries' SOC and SOH. However, real-time determining the SOC in practical situations is difficult with the present methods.

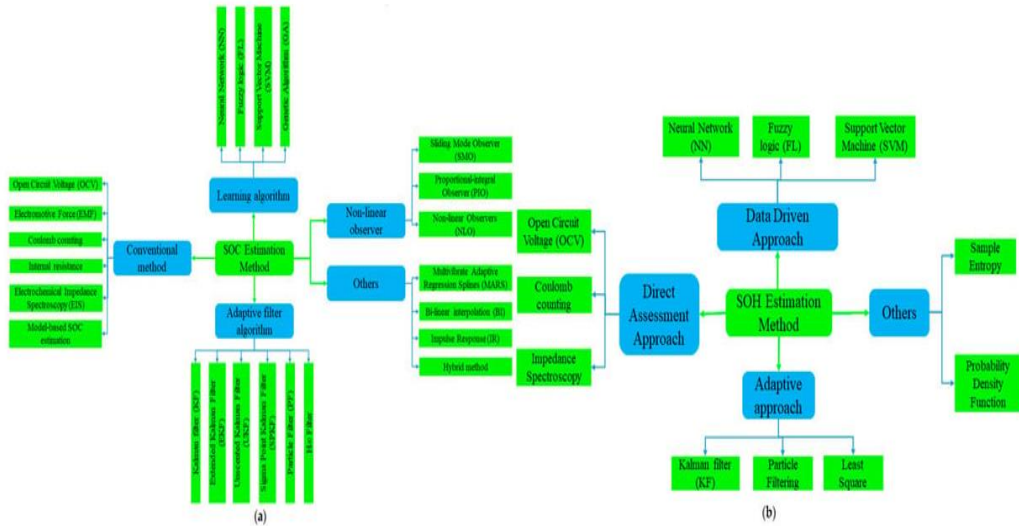

Figure 3: Taxonomy of SOC and SOH estimation method, (a) SOC estimation; (b) SOH estimation.

Optimal Charging Problem and Characterization

The current charging technique takes a long time to charge an EV's batteries with a battery pack, which is less efficient and less safe. Therefore, balancing the charging efficiency, heat, battery lifespan, and degradation is challenging. There are several concerns with the real-time estimations of SOC and SOH in a BMS since they are time-demanding and inaccurate. Simple OCV-SOC models for real-time SOC assessments are less accurate and accumulate errors from other estimated parameters.

Battery Models

BMS batteries are typically characterized using physical (equivalent, electrochemical) and data-driven (hybrid) techniques. Testing in different environments is impossible due to the need for precise conditions. Data-driven algorithms' performance and computational

complexity highly depend on test data and training procedures. It has resulted in several clever techniques/algorithms.

Battery Charger and Discharging Issue

Another problem for BMS is the lack of universal battery chargers. Custom battery chargers tend to be more compact and intended for domestic use, leading to increased electrical clutter and environmental waste. As a result of the wide variety of batteries in use, battery charger designers must handle this issue. Working with damaged or old batteries necessitates using safe-discharge batteries, which can be dangerous.

Conclusions

Battery management is a critical concern for EV adoption due to battery life cycle, safety, cost, and temperature difficulties. In contrast to other works that analyze only one or two aspects of battery management, this work examines all facets. This study discusses various BMS topologies, features/functions, requirements, and comparisons. For the BMS, six points were highlighted, especially focused on battery cell charge balancing techniques. BMS's main challenges are real-time SOC and SOH estimation, optimal charging problems, thermal management and runaway, and battery recycling and reuse.

Abstract

The conventional machining of AMCs is complex due to the presence of reinforcements that affects the cutting tool and surface quality of the machined components. To overcome these difficulties, non-conventional machining methods are utilized. Electrochemical machining (ECM) and chemical machining (CM) processes are thermal-free processes, but CM is applicable only for chemically conductive material. Electrochemical machining (ECM) processes play a significant role in the fabrication of micro components because of their advantages such as higher MRR (Material Removal Rate), no tool wear, good surface finish and better precision control. Electrochemical micromachining (ECMM) has been employed irrespective of difficult-to-cut materials, hard materials and tool wear; and it is one of the non-conventional non-contact machining techniques and hence, ECM is proposed for machining AMCs (Aluminium Metal Matrix Composites). The dominant parameters are selected for electro chemical machining for Al metal matrix. The parameters like voltage, current & electrolyte concentration, duty cycle are selected in order to achieve the good quality of profile cutting as well as minimum dimensional distortion.

INTRODUCTION

The manufacturing sector explores different materials in the present time for their products, which satisfy their specific requirements. In certain applications like aerospace, automobile and shipbuilding high strength-to weight ratio is the requirement for the components. This initiated the development of newer materials with higher strength combined with lighter weight. The developments of composite materials satisfy the above requirement. The shaping of the composite materials posed a challenge, and requirements of special type of machining are inevitable. Unconventional machining solved the above problem to the larger extent. However, the quality of the machined components is mainly based on the output parameters such as Metal removal rate (MRR) and Surface Roughness (SR). Further, the above parameters are optimized to reduce the cost of the quality components.

The present study plays an imperative character in determining the optimum parameters of machining processes with respect to output parameters. The systematic method of analyzing and optimizing process parameters when composites or any material processed in unconventional machining process are explored through Design of Experiments, formation of single-objective optimization using have been illustrated in the present thesis.

LITERATURE REVIEW

The published literatures have been collected and reviewed carefully for exploring the status in machining process optimization of MMCs with different machining process. The collected literatures are classified into various categories such as literatures based on aluminum matrix composites, electro chemical machining, modeling and optimization highlighting the methodology adopted and the outcome of the research. The research gap has been identified after careful review of literatures, and the objectives for the present work have been derived and highlighted at the end of this chapter.

Senthilkumar et al. [1] developed the linear regression mathematical model by means of XLSTAT software. Taguchi L27 orthogonal array method with 54 trials was employed in the design of experiments. The samples were prepared in the composition of an aluminium alloy reinforced with varying SiC proportion of 5, 10, and 15 wt %. These composites were prepared by the stir casting method. NaCl was used as the electrolyte solution. While

machining the composites of the cast aluminum alloy A356-SiC particles via ECM, the influence of the process parameters such as applied voltage, tool feed rate, electrolyte concentration, and percentage of reinforcement on the MRR was studied.

Pramanik et al. [2] reported that the MRR increases with higher such process parameters as applied voltage, tool feed rate, electrolyte concentration, and electrolyte flow rate. A higher machining current in the inter-electrode gap results from an increase in voltage and electrolyte concentration. When the gap between the tool and workpiece is reduced, the tool feed rate increases leading to a higher current density.

Senthilkumar et al. [3] studied the electrochemical machining performance of Al-10 wt % SiC composites. The composites were prepared by the stir casting technique. They revealed that at low voltage applied in ECM, a high SR and a low MRR resulted. But an increased electrolyte flow rate resulted in the acceleration of the chemical reactions, accordingly increasing the MRR. When the applied voltage exceeds a certain limit and the electrolyte flow rate is constant, then more heat is produced that subsequently deteriorates the surface of the machined workpiece.

Hihara et al. [4] used ECM for machining Al-SiC composites using calomel as the tool material and aqueous NaNO_3 as the electrolyte solution. During the anodic dissolution, the matrix material was removed, whereas the inert SiC reinforced particles were removed by the electrolyte flow. The reduction in applied voltage and tool feed rate caused a high SR due to unsteady and nonhomogeneous anodic dissolution. Moreover, as a result of a high current density caused by a higher tool feed rate and the existence of SiC particles in Al matrix, the pits on the workpiece surface were formed. In this process, hydrogen bubbles were produced, which obstructs the anodic dissolution, which, in turn, leads to the formation of the nodular work surface profile. A high electrolyte flow rate that aids in the removal of the hydrogen bubbles and rotation of the tool at a particular speed, could prevent the nodular work surface profile.

Toptan et al. [5] reported on experimentation of ECM of aluminium reinforced with (2.5, 5.0, and 7.5 wt %) B_4C and studied the MRR. They developed a mathematical model for the MRR and applied ANOVA for the analysis. In that model, the mathematical relationship was established in between the input parameters such as applied voltage, tool feed rate,

electrolyte concentration and percentage of reinforcement and the response parameter such as the MRR.

Sankar et al. [6] studied the performance of ECM of AA7075-B4C composites and optimized the responses of the MRR and SR by the response surface methodology, and then the result was analyzed by ANOVA. NaNO_3 was used as the electrolyte in this process. In that study, they considered current, voltage, and tool feed rate as input parameters. It was observed that such process parameters as voltage and tool feed rate highly influenced the MRR and SR. Therefore, the maximal MRR and the minimal SR was achieved at: 8 V applied voltage, 217 A current, and 0.3 mm/min tool feed rate.

Solaiyappan et al. [7] studied the performance of machining of AA6061 alloy with 10 wt % Al_2O_3 and 5 wt % SiC hybrid composites using straight ECM and that optimized by using hybrid fuzzy-artificial bee colony algorithm. They examined the influences of such process parameters as applied voltage, current, tool feed rate, electrolyte concentration, electrolyte flow rate and interelectrode gap on such performance parameters as the MRR, SR, and ROC.

EXPERIMENTAL SETUP

Electro Chemical Micro Machining (ECM) is one of the advanced machining processes where material removal takes place through electrolysis phenomena. It is best suited for materials which are difficult to be machined by mechanical machining process. The process is started in the presence of an electrolyte flow that is circulated with the help of special pump filling the gap between anode (work piece) and cathode (tool). Electrolyte flow is adjusted by flow control valve. The machining is achieved by sinking of tool forming its replica. During the operation sophisticated control panel takes care of any damage to the machine by overload and short circuit protections. After desired time interval hooter gives an indication of completion of the time / process. The small machining area with given power supply can be machined within 30 minutes to one hour.

Figure 1: ECMM Setup

Working principle of ECMM

It works according to the principle of electrolysis. When electric pulses are passed between anode and cathode, the electrons cross the gap and material from the work piece dissolved and desired shape of material is obtained. The voltage is changed along with the duty cycle is analyzed. Electrochemical machining works inverse as electroplating process. Metal is removed from anode into electrolyte and convert into slag form by reacting opposite ions available in electrolyte. In ECM, the electrolyte is so chosen that there is no plating on tool and shape of tool remain unchanged. Generally, NaCl into water takes as electrolyte. The tool is connected to negative terminal and work is connected to positive terminal. When the current passes through electrode, reaction occur at anode or work piece and at the cathode or tool.

COMPONENTS OF ECM

Servo motor

A servomotor is a rotary actuator or linear actuator that allows for precise control of angular or linear position, velocity, and acceleration. It consists of a suitable motor coupled to a sensor for position feedback. It also requires a relatively sophisticated controller, often a dedicated module designed specifically for use with servomotor

Figure 2: Servo Motor

DC Pump

A pump is a device that moves fluids (liquids or gases), or sometimes slurries, by mechanical action. Pumps can be classified into three major groups according to the method they use to move the fluid: direct lift, displacement, and gravity pumps.

Pumps operate by some mechanism (typically reciprocating and rotary) and consume to perform moving the fluid. Pumps operate via many energy sources, including manual operation, electricity, engines, or wind power come in many sizes, from microscopic for use in medical applications to large industrial pumps.

Figure 3: DC Pump

Pulsed rectifier

The device which operates at above 30V is called an electrical device and the device which operates with less than 30V is called electronic voltage. Even though the electronic devices like transistors are used to amplify the analog signals, they eventually need DC voltage biasing to perform that task. Likewise, so many electronic devices operate on only DC which cannot sustain any voltage changes.

Reservoir Tank

Reservoir is fixed on the base of the experimental set up. It contains the electrolyte and it holds the workpiece table. The capacity of the tank is to carry up to 1.5 liter of electrolyte.

ECM MACHINE PARAMETERS

Tool Feed Rate

In ECM procedure gap around 0.01 to 0.07 mm is maintained between the tool and work piece. The electrical resistance is small for small gap between the tool and work and maximum current and therefore maximum material will be removed. Depending on how quickly the metal has to be removed, tool is fed towards work.

Material Removal Rate

Electrolysis is the basis of material evacuation. Faraday proposed two laws for this, initial one is "the chemical change created by an electric current, which is the measure of any material dissolved or deposited, is directly proportional to amount of current supplied". Second is "The amount of different constituents dissolved by the same amount of electricity are proportional to their chemical equivalent weights ". MRR is a function of feed rate. A steady spacing between the tool and the work is in this manner established. The real advantages of the metal removal rate procedure are that they don't bring about certain undesirable surface impacts which emerged in traditional machining processes. The main advantages are that they are stress free machining, burr free surfaces, reduced tool wear and cancelation of thermal damage to the work-piece. These methodologies have no impact on mechanical properties, for example, yield strength, ultimate strength, hardness, ductility etc.

Overcut

ECM can deliver surface finish of $0.45\text{ }\mu\text{m}$ by turning of tool or work. Any imperfection on tool face produce replica on work piece. Tool surface therefore in this manner be polished. The finish is better in harder material. For ideal surface finish, careful electrode design, maximum feed rate, and surface improving additives in electrolyte are chosen. Low voltage reduces the equilibrium inter electrode gap and result in better surface finish and tolerance control. Low electrolyte concentration results in reduced machining gap and better surface finish. Low electrolytic temperature additionally improves surface finish.

Electrolyte and its concentration

The electrolyte solution is essential for the electrolysis process to work. An electrolyte in ECM performs three basic functions, which are as follows;

- Completing the electrical circuit and allowing the large current to pass.
- Sustaining the required electrochemical reactions.
- Takes away the heat generated and the sludge.

Electrical conductivity of the electrolytes must be high, toxicity and corrosiveness should be low.

Tool design

Any good conductor can be satisfactorily used as tool material because there is negligible tool wear in ECM process. But it must have sufficient strength to withstand the hydrostatic force, brought on by electrolyte when it is discharged at high velocity through the hole in the middle of tool and work. In order to allow electrolyte to pass along the bore in the tool the tool is made hollow for drilling holes. Most commonly used tool material is copper. Some materials like graphite, brass and copper tungsten are used since they have capability of Machining and non-corrosive properties.

Current

In ECM, current plays a vital role. The material removal rate is directly proportional to the current (i.e. higher is current, more will be material removal rate). Generally, this increase is observed up to a certain value and when current exceed beyond this level it negatively affects finishing and accuracy of work piece.

OPTICAL MICROSCOPE IMAGES

The optical microscope, often referred to as the light microscope, is a type of microscope that commonly uses visible light and a system of lenses to magnify images of small objects.

The microscope has a digital camera and is attached to a computer image analysis covers a range of techniques to gather quantitative analysis or measurements from images using sophisticated software. It is also used to calculate the front and back hole diameter. It is helpful to determine the material removal rate and overcut.

FIELD EMISSION SCANNING ELECTRON

MICROSCOPE IMAGES

Field emission scanning electron microscopy (FESEM) provides topographical and elemental information at magnifications of 10x to 300,000x, with virtually unlimited depth of field. Compared with conventional scanning electron microscopy (SEM), field emission SEM (FESEM) produces clearer, less electrostatically distorted images with spatial resolution down to 1 1/2 nano meters – three to six times better.

Principle of Operation

A field-emission cathode in the electron gun of a scanning electron microscope provides narrower probing beams at low as well as high electron energy, resulting in both improved spatial resolution and minimized sample charging and damage.

Figure 6: Field Emission Scanning Electron Microscope (FESEM)

PROBLEM IDENTIFICATION

Aluminium metal matrix composites (AMMCs) are widely used in the applications of industries such as aerospace, automobile, defense, etc., because of certain significant properties like high strength-to-weight ratio, high stiffness, and high hardness, low wear rate and low coefficient of thermal expansion. Generally, AMMCs are reinforced with some ceramic abrasive particles, which leads to abrasive action during machining. When machining of AMMCs is done with conventional techniques, then high tool wear is reported resulting in the decline of the surface integrity of the material. Machinability of composites

is reduced while performing the traditional machine operations such as turning, milling, threading, etc. because those are hard-to-machine materials. In the traditional method, heat is generated during machining at the interface of tool and chip, which influences the surface integrity of the workpiece. Machining cost also, increases in the conventional machine to process hard particles reinforced AMMCs. Many researchers reported the machining of metal matrix composites by unconventional machining processes. Laser beam machining and electrical discharge machining (EDM) provide more sub-surface damage to the workpiece than electrochemical machining (ECM). Among the unconventional techniques, ECM is the most significant one that could be employed for machining hard or difficult to cut materials. In this process, metal is removed from the electrically conductive workpiece by controlled dissolution. Here, tool and workpiece are considered as cathode and anode, respectively; both are separated by an electrolyte solution. It is mainly used for the manufacturing the complex shape components for automotive, aerospace, defence, medical and electronics industries such as engine castings, non-circular holes, bearing cages, forging dies and moulds, turbine blades, artillery projectiles, and surgical implants, etc.. Besides, there are some important merits of ECM such as no stress, no burrs, longer tool life, damage-free machined surface.

METHODOLOGY

DESIGN OF EXPERIMENT&TAGHUCHI APPROACH

Taguchi's Approach to Parameter Design Taguchi's approach to parameter design provides the design engineer with a systematic and efficient method for Determining near optimum design parameters for performance and cost. The objective is to select the best combination of control parameters so that the product or process is most robust with respect to noise factors. A brief overview of Taguchi's approach for parameter design.

Determine the Quality Characteristic and to be optimized the first step in the Taguchi method is to determine the quality characteristic to be optimized. The quality characteristic is a parameter whose variation has a critical effect on product quality. It is the output or the response variable to be observed. Examples are weight, cost, corrosion, target thickness, strength of a structure, and electromagnetic radiation.

Identify the Noise Factors and Test Conditions to identify the noise factors to produce a negative impact on system performance and quality. Noise factors is a parameter which may either uncontrollable or are too expensive to control. Noise factors consist of variations in deterioration of components with usage, environmental operating conditions and variation in response between products of similar design with the similar input.

Identify the Control Parameters and Their Alternative Levels to identify the control parameters thought to have significant effects on the quality characteristic. Control (test) parameters are those design factors that can be set and maintained. The levels (test values) for each test parameter must be chosen at this point. The numbers of levels, with related test values, for each test parameter was defining the experimental region.²⁹

Design the Matrix Experiment and Define the Data Analysis Procedure A specific study is required to get proper orthogonal arrays for the noise and control. Taguchi gives many standard orthogonal arrays and corresponding linear graphs for this function. After selecting the appropriate orthogonal arrays, a process to simulate the variation in the quality characteristic due to the noise factors wants to be defined. A general approach is the use of Monte Carlo simulation. However, for an precise estimation of the mean and variance, Monte Carlo simulation requires a huge number of testing conditions which can be expensive and time consuming. As a substitute, Taguchi proposes orthogonal array-based simulation to assess the mean and the variance of a product's response ensuing from variations in noise factors. Using this approach, orthogonal arrays are used to sample the domain of noise factors. The experimental results for each combination of control and noise array experiment are denoted by Y_{ij}

Conduct the Matrix Experiment the Taguchi method may be used in any condition wherever there is a controllable process. The controllable process can be a real hardware experiment, computer models or systems of mathematical equations that can be effectively model for the response of many products and processes.

Analyze the Data and Determine the Optimum Levels The optimal test parameter pattern within the experiment design must be determined, after the experiments have been conducted. For analysis of the results, the Taguchi method uses a statistical measure of performance called signal to noise (S/N) ratio borrowed from electrical control theory. The S/N ratio produced by Dr. Taguchi is a performance measure to select control levels that

most excellent cope with noise. The S/N ratio takes both the mean and the variability into relation.

CONCLUSION

The result showed that the machining rate for heat treated tool is 2 times better than the non-heat-treated tool. Field emission scanning electron microscope (FESEM) images show much difference in surface structure for heat treated tool and non-heat-treated tool. The findings provide valuable understandings on heat the tool to improve the performance of EMM systems.

Abstract

A simple manually operated hand grain suction machine made of locally available materials using local manufacturing technology was designed, fabricated, and tested for collecting and bagging of grains (paddy) dried on concrete pavement. The invention belongs to the technical field of agricultural machines, and relates to a tool applied when grains are collected after being aired, in particular to a manual grain bagging machine. Grains are automatically loaded into a dustpan by pushing the manual grain bagging machine with hands, a hand wheel of a drive assembly is rotated so that a gear can push a rack to move upwards at first and then move horizontally, and a stop bar on the dustpan is blocked by a left arc baffle and a right arc baffle so that the dustpan can tilt to pour the grains into an opening bag. A simple manually operated grain collector and bagging had the following major components: frame, wheel, long pipe, vertical stand frame (bars), horizontal bars, collector, and bag. Radial flat bladed type base plate, slot bar, sweeping box, bagging area, frame and the conveyance system. Results showed significant differences on the collecting capacity, and noise level. Other parameters such as collecting efficiency, air velocity, augmented cracked grain percentage.

Abisha M V, Bavanya S, Deenadayalan V (2015) A simple mobile vacuum engine-driven pneumatic paddy collector made of locally available materials using local manufacturing technology was designed, fabricated, and tested for collecting and bagging of paddy dried on concrete pavement. The project "Vacuum collector for bagging of paddy" is designed at the aim of time consumption, low man power and with simple vacuum mechanism. ICE farming in the Philippines took a complete turn when modern technologies were introduced which include the adoption of high yielding varieties, application of inorganic fertilizer, better crop pest control, water management, and other improved farming practices. Paddy is collected in the cylinder at a certain suction pressure by using vacuum. This principle is based on industrial vacuum cleaners.

Emmanuel. B (2009) before designing the CAD model, it was essential to consider various components necessary for the designing such as; threshing drum size and speed, power required for threshing and frame design. Among the threshing methods, the threshing of grain through impact force at an average speed (350 to 500 rpm) provide minimum seed damage. Therefore, threshing of rice paddies is based on the principle of impact force generated by beating action of the spikes. The machine has the five main components that have to be designed and be fabricated accurately for its efficient working. These are: the threshing unit, power transmission system, screening unit and a collecting unit.

Helen Gavano. F (2006) said that this is a mechanical device specifically designed to efficiently store rotational energy. It smoothens the power output of an energy source. It consists of 4 sprockets and two shafts. The first shafts carry one smaller sprocket and a larger sprocket, the smaller sprocket is connected to the larger sprocket on the bicycle and the larger sprocket transfer motion to the smaller sprocket on the second shaft. The second sprocket on shaft is connected to the sprocket at the drum hence transfer motion to the drum.

OBJECTIVE OF THIS WORK

Enhancing Efficiency: Develop a machine capable of efficiently suctioning grains from fields or storage areas, reducing manual labour and increasing overall productivity.

Improving Ergonomics: Design the machine with ergonomic features to ensure ease of use and reduce operator fatigue during prolonged operation.

Optimizing Suction Performance: Achieve optimal suction power and efficiency to effectively handle a variety of grain types, including different sizes and moisture levels.

Ensuring Safety: Implement safety features to minimize the risk of accidents or injuries during machine operation, both for the user and surrounding personnel.

Minimizing Grain Loss: Develop mechanisms to minimize grain loss during suctioning and transportation, ensuring maximum yield retention.

Customizability and Adaptability: Design the machine to be adaptable to various field conditions and grain types, with options for customization based on specific user requirements.

Durability and Reliability: Utilize robust materials and construction techniques to ensure the machine's durability and reliability under challenging agricultural environments.

Ease of Maintenance: Design the machine with easy-to-access components and straightforward maintenance procedures to minimize downtime and prolong its operational lifespan.

Energy Efficiency: Incorporate energy-efficient components and design principles to reduce power consumption and environmental impact.

Cost-Effectiveness: Develop a machine that offers a balance between performance and cost, ensuring affordability for farmers and agricultural businesses.

Compatibility with Existing Equipment: Ensure compatibility with existing grain handling and processing equipment commonly used in agricultural operations, facilitating seamless integration into existing workflows

Compliance with Regulatory Standards: Ensure that the design and operation of the machine comply with relevant safety and regulatory standards governing agricultural machinery.

User Training and Support: Provide comprehensive user manuals, training materials, and ongoing support to ensure proper usage and maintenance of the machine by operators.

Feedback Incorporation: Establish mechanisms for gathering user feedback and incorporating suggestions for continuous improvement and refinement of the machine's design and functionality.

Contribution to Sustainable Agriculture: Contribute to the promotion of sustainable agricultural practices by developing a machine that improves efficiency, reduces resource consumption, and minimizes environmental impact in grain handling operations.

HAND GRAIN SUCTION MACHINE:

AC Motor:

AC Motor centrifugal fan, filter are three important design items to take care of to improve the performance of the grain aspiratory machine. Friction, noise, power, consumption, suction pressure are the design variables that govern the aerodynamics and mechanical device factors. The nozzle and narrow compartment geometry play important role in maintaining the pressure and grain flow pattern. A motor is the heart of any machine so does the paddy bagging machine. Its attached to a fan which forces air over the exhausted unit. The suction pressure and performance depends on the motor power only. High power motor offers more sucking capabilities eventually but you should look other factors as well to determine the best performance of the paddy bagging machine. It is also suitable to drive agitators independently of the main motor.

**AC MOTOR****Bearings:**

Bearing are Mechanical assemblies that consists of rolling elements & assist object rotation. Bearing support, the rotating shafts of the Wheels & allow them to rotate more smoothly. The main function of bearing of a rotating shaft is to transmit power from one end to the other i.e. it plays a vital role between two rotary moving parts.

**BEARING****The Cylinder:**

A hollow cylinder pipe is a cylindrical tube with an empty space inside, allowing for the passage of fluids or gases. It's commonly used in plumbing systems for water distribution, drainage, and sewage conveyance.. In construction, hollow cylinder pipes are utilized for structural support, particularly in columns and beams. Engineering applications often employ hollow cylinder pipes for conveying materials such as oil, gas, or chemicals in industrial processes.

CYLINDER

Spur Gear:

The theory of spur gears revolves around the principles governing cylindrical gears with straight teeth. These gears transmit motion and power between parallel shafts. Key concepts include gear ratio, tooth profile, and contact pattern. Spur gears are known for their simplicity, efficiency, and widespread use in various mechanical systems.

SPUR GEAR

Frame and Screw Conveyor:

The frame is an important part of the equipment. It must provide flexibility which is equivalent of suspension to give good grip. So, the proposed mode equipment does not consist of any suspensions. It is made up of mild steel L- section having a cross section of 31mm X 31mm. It consists of 4 channels, which are cut into the length, of 610 mm and other 2 Pieces are cut into 550 mm length. And also, it can be arranged according to the need as

shown in the figure. The arranged pieces are welded at the joining section to form the base frame of the equipment.

Learnings from the project.

- Day to day engineering concept will solve many industrial problems.
- Designing and making of prototype.
- Field study of other competitive equipment's.
- Dealing with associates Communication.
- Discipline, Punctuality, Dedication, Commitment and Time management.

This project work has provided us an excellent opportunity and experience, to use our limited knowledge. We gained a lot of practical knowledge regarding, planning, purchasing, assembling and machining while doing this project work. We feel that the project work is a good solution to bridge the gates between institution and industries. We are proud that we have completed the work with the limited time successfully. The Paddy collecting and bagging machine using vacuum is designed with satisfactory conditions. We are able to understand the difficulties in maintaining the tolerances and also quality. We have done to our ability and skill making maximum use of available facilities.

SCOPE FOR FUTURE WORKS

The present work may be extended in one of the following ways.

- Grain collector can be further implemented to fixing the motors to lift the grains. The system can be easily configured to require one.
- It can be further implemented by using solar panels with battery operated to run the vehicle.
- The developed mini grain collector is larger in size and there is a scope for making it more compact and light in weight.

CONCLUSION

Paddy collecting and bagging machine using vacuum is useful for collecting grains from the floor and a conceptual model was designed successfully. It has considerable potential to greatly increase the efficiency of collecting grain with comparison of other traditional available techniques. The main task now is to promote this technology and have available to

users at an affordable price. The grain collector is made up of local components in workshop. This can be sourced at an inexpensive price from local traders. By using local materials, collecting of grains can be achieved.

A manual paddy bagging machine that collects grains from the concrete pavement floor through the collecting bin and made to fall into the bag placed adjacent to it. This machine has vast application in India due to lack of electricity and investment for the poor farmers. This became the main motivation to fabricate this manual bagging machine. This machine reduces the grain collecting time and labour cost. As the main goal to reduce the usage of electricity we don't suggest the future scope with motors rather the belt drive mechanism can be designed to reduce the time and mechanical force of labour or operator

ABSTRACT

The abstract delves into the technical intricacies of the design, outlining the synchronization of treadmill and bicycle components. Special attention is given to the efficiency of the DC power generator, exploring its capacity to harness and convert the energy produced during exercise. The project's innovative approach is underscored by its potential to contribute to clean energy initiatives and promote eco-friendly fitness solutions. Consideration is also given to the health benefits of this hybrid exercise device. By combining the cardiovascular advantages of cycling and walking, users can experience a comprehensive workout that targets various muscle groups. The abstract emphasizes the potential impact on personal fitness routines and the broader fitness industry. Moreover, the abstract discusses the applications of the Treadmill Bicycle beyond individual use. The generated DC power could find applications in powering small electronic devices or feeding into local energy grids. The project's interdisciplinary nature, bridging fitness and renewable energy, is highlighted as a key strength. This Treadmill Bicycle with a DC power generator represents an innovative convergence of exercise and sustainable technology. The abstract encapsulates the project's technical aspects, health benefits, and potential societal contributions, positioning it as a pioneering solution at the intersection of fitness and renewable energy.

Keywords

DC power generator, roller, shaft, Treadmill belt, free wheel.

INTRODUCTION

The treadmill bicycle is completely a new way of moving which is designed mostly for runners. Basically, using a treadmill is similar to running, hiking or walking. Think about the last time you were riding a bike over a few obstacles such as train tracks, potholes, speed bumps etc. The possibilities are you stood up on the pedals to improve your balance when crossing the obstacle. Basically, the treadmill bicycle will provide the rider a well-balanced position the entire time. Since it uses no fuel it a very conventional option for people in their busy schedule to take care of their health completely. People with a busy schedule will also be able to take care of their health and physical fitness. Above all, it is not a conventional treadmill to make use of only in closed rooms, people using treadmill bicycles can roam around freely on roads as well. This project overcomes the drawback of the conventional treadmill which is stationary and moreover the jogger gets exposed to the natural atmosphere too. So this proposed methodology provides an ultimate solution by making use of the wheels and making the treadmill bicycle a walking cycle. The walking cycle has a simple mechanism, operated with free wheels, gear chain, bearing shaft and links arrangement. The conversion of the linear motion into rotary motion is done by the gear chain and free wheel mechanisms of the linkages, which involves very simple movements. The rotary motion is again converted into linear motion of the cycle through mechanical linkages (gear chain and free wheels) arrangement. The conveyor system is either a continuous movement or intermittent which depends on the person's usage. So a basic free wheel mechanism with bearings is designed with time delay which can be used to halt the movement when necessary. This invention relates to improvements in transport bike or a cycle. The Walking Bicycle is the one, which combines walking and cycling into one activity. The Walking Bicycle combines the two activities into a linear motion, allowing you to propel yourself forward at desired speed, simply by walking on the belt provided. Usually, the operation of the walking cycle machine is controlled by the user itself by simply walking on the treadmill belt and also balancing the cycle. The operating speed of the walking cycle differs on the amount of force applied by the user.

LITERATURE REVIEW

Manish Debnath et al, Generation of electricity by running on a leg powered treadmill [2015].

Manish Debnath et al (2015) proposed an eco-friendly method of generating electricity. They proposed the feasibility of this method for the remote areas where the electricity is beyond the reach of common people. Their suggested treadmill can be easily operated by anyone as the small connected DC generators require very small torque. Their method can reduce a significant portion of our consumption of fossil fuel, spent for generating electricity.

Gopinath et al (2018) proposed a technique that can produce electricity with the assistance of electricity components that create use of the energy of human footsteps and storing of the charge by converter employed in the circuit for future applications. They suggested the need of constant increase of power to be met by putting in the systems in heavily packed places to overcome the energy crises however conjointly build up a healthy encompassing.

Ravindra Burkul et al, Treadmill Bike [2018].

Ravindra Burkul et al (2018) developed a branch and bound approach to optimize the 'Treadmill Electric Bicycle' serving the purpose of exercise and to reduce the use of non renewable energy resources. They created a platform in which mechanical energy is converted into linear motion. Their proposed prototype can be a good promoted area to use the energy being wasted on treadmills in fitness centres, devices, and it relates particularly to devices for transferring people, small in number like that of a

not only to save energy but also to create a new idea of energy distribution in electrical field which is a common need for everyone in future.

V.R. Gandhewar et al, Utility and Application of Treadmill Bicycle [2017].

Gandhewar et al (2017) proposed a project creating a platform in which mechanical energy is converted into linear motion. Their highly fuel-saving technology based prototype was promised to utilise the energy being wasted on treadmills in fitness centres. They investigated its application as an indoor locomotive device infrastructure with large roof span i.e. malls, warehouse, open markets, large office spaces, etc.

Abhiram et al (2017) proposed a new model of tricycle which is combination of treadmill and tricycle. They investigated that the treadmill tricycle can be used in place of regular bike at reduced initial and running cost. They suggested it as a future vehicle and it does not emit any pollutants, it is an eco-friendly vehicle.

Kunal Titare et al, Design and Fabrication of Power Generating Manual Treadmill [2018].

Kunal Titare et al (2018) observed during the test run of the project that the current was obtained at some specific speed. They further calculated the current output, taken out from the motor to battery and investigated that the assembly of treadmill so obtained is free from any failure and deformation.

WORK METHODOLOGY

The fabrication of the treadmill traveller is very advantageous because of its simple construction and easy working principle. To say in a one line, this machine follows the action of the user. That is, when the driver walks forward, the machine moves forward and when he walks backward, the machine moves backward. A treadmill setup is made so that the operator can walk on the belt. A handle is placed in the front for the controlling of the vehicle. The rollers above which the conveyor belt (treadmill belt), held in tension are coupled to the wheels of the machine, usually rear wheels. The rollers are connected by a suitable arrangement for efficient transmission of motion thus having minimal losses during the transmission of motion. The frame of the machine is designed in such a way that it is balanced and the operator doesn't put any effort in balancing the machine. Now when the operator walks forward, the conveyor belt moves in one direction which makes the wheels of the machine to rotate so that the machine moves front. When he walks backwards, the motion direction of the belt is reversed and thus the vehicle moves backwards.

LIST OF COMPONENTS:

- Rectangular pipe for frame
- Hollow circular pipe for roller
- Bearings

- Shafts
- Treadmill belt
- Bicycle fork
- Bicycle handlebar
- Bicycle wheels
- Bicycle sprockets
- Bicycle chain
- Dynamo
- Inverter

RECTANGULAR PIPE FOR FRAME:

- A Rectangular pipe is used to make a frame structure.
- A frame is often a structural system that supports other components of a physical construction and/or steel frame that limits the construction's extent.

HOLLOW CIRCULAR PIPE FOR ROLLER:

Hollow circular pipes are also known as round steel tubes. They are a common type of steel section used in many industries. Circular hollow sections are rolled from slit coil or steel sheet.

A treadmill roller is a hollow tube product. When buying a hollow circular pipe for a treadmill roller, you can consider these factors:

- Size: The size of the roller.
- Construction: Whether the roller is solid or hollow.
- Thickness: The size of the rolls goes up with the square of the increase in thickness.

BEARING:

The main purpose of bearings is to prevent direct metal-to-metal contact between two elements that are in relative motion. This prevents friction, heat generation and ultimately, the wear and tear of parts. It also reduces energy consumption as sliding motion is replaced with low-friction rolling.

A ball bearing is a type of rolling-element bearing that serves three main functions while it facilitates motion: it carries loads, reduces friction and positions moving machine parts.

Ball bearings use balls to separate two “races,” or bearing rings, to reduce surface contact and friction across moving planes.

SHAFTS:

Shafts are used in treadmills to transmit power between the source and the machine absorbing power.

For example, in a treadmill bicycle, a sun gear attached to the treadmill roller drives a gear on a shaft. This shaft is then transmitted to another shaft by increasing the gear ratio by 2.5 times. This shaft is then coupled with the gear fitted on the wheel.

Other uses of shafts in treadmills include:

Roller shaft: Extends through the treadmill rollers.

TREADMILL BELT:

A conveyor belt is the carrying medium of a belt conveyor system (often shortened to belt conveyor). A belt conveyor system is one of many types of conveyor systems. A belt conveyor system consists of two or more pulleys (sometimes referred to as drums), with an endless loop of carrying medium-the conveyor belt-that rotates about them. One or both of the pulleys are powered, moving the belt and the material on the belt forward. The powered pulley is called the drive pulley while the unpowered pulley is called the idler pulley. Today there are different types of conveyor belts that have been created for conveying different kinds of material available in PVC and rubber materials. The belt consists of one or more layers of material. Many belts in general material handling have two layers. An under layer of material to provide linear strength and shape called a carcass and an over layer called the cover.

BICYCLE SPROCKET:

Sprockets are sturdy wheels with teeth that lock onto a chain. As the sprocket spins, the teeth grab onto the chain and move other parts that interlock with the chain. This sequential series of operations allows for simple and controlled rotational movement of larger equipment and machinery.

DYNAMO:

In a bicycle generator, a small dc generator is attached to one of the wheel of the bicycle. When the bicycle runs, the rotor which is attached to the cycle wheel also rotates and emf

will be generated across the output terminals of the generator. This emf is then generally used for lighting the head-light of the bicycle and stored in battery.

BICYCLE CHAIN:

A bicycle chain is a roller chain that transfers power from the pedals to the drive-wheel of a bicycle, propelling it. A bicycle chain is made up of a series of links, comprised primarily of side plates, pins, and rollers. A chain is designed to mesh with the chainrings and cassette on the bike's drivetrain, to transfer your power through the pedals into forward propulsion.

Most bicycle chains are made from plain carbon or alloy steel, but some are nickel-plated to prevent rust, or simply for aesthetics.

INVERTER:

An electrical inverter is a device that converts Direct current (DC) to Alternating current (AC).

In this project we use a inverter that will step up the DC power from 12V to 27V. this inverter has an inbuilt battery with 12V 1.2Ah capacity this inverter will stores an energy with help of inbuilt lead acid battery . this inverter has a capability to run three 9V CFL bulbs for 3 hours.

It is commonly used to power AC devices like appliances, from dc source such as battery.

ADVANTAGES:

- The components used for the fabrication are simple and easily available.
- The cost of the system is less.
- No need of separate time for exercising.
- No need of skilled operators to operate this machine.
- Less maintenance is needed.
- Compact in size.
- Less weight.
- Easily portable.
- Inverter charges the battery automatically.
- Simple in construction.

APPLICATION:

- Exercise: Treadmill bicycles can help maintain a proper physique. They can also help burn fat, and can be used outdoors or on the way to work.
- Reduce non-renewable energy sources: Treadmill bicycles can be used to reduce the use of non-renewable energy sources.
- Connect with nature: Treadmill bicycles can allow people to connect with nature while running on a treadmill.
- Save time: Treadmill bicycles can save time for exercising.
- Travel: Treadmill bicycles can be used to travel from one place to another.

3D CAD MODEL

CONCLUSION

- Exercise Treadmill bicycle helps in maintaining proper physique. Physical fitness is of utmost importance in day to day life.
- People often get bored while exercising in a closed room such as gym. By using treadmill bicycle one can exercise outdoors in fresh air.
- Fuel saving People often use vehicle for travelling over short distance. This causes unnecessary wastage of fuel.
- Due to use of treadmill bicycle over short distance a large amount of fuel can be saved.
- Travelling Treadmill bicycle can be used for travelling over short distances. One can also exercise while travelling over short distance.

- Eco- friendly Treadmill bicycle does not require any fuel. Therefore it does not emit any pollutants. So it is an eco-friendly vehicle.

ABSTRACT

Agriculture is the major sector in the world that plays a vital role in developing the economy of a nation. Agro technology is the process of implementing the recent technologies to develop the crops that are being produced. The use of agro technology not only helps in improving the efficiency of the crop that are being produced but also helps in developing devices that are suitable for doing mechanical works in the fields. This results in minimization of the total cost of production, saving of time and reduction in the effort involved in the process. The new technology should also be economically feasible and hence the behaviour of the technology and its role in the society is an important consideration before developing a new product or process. In this work a seed sowing machine has been developed that help the farmers in harvesting the best crop with least efforts. A mechanical device that helps in sowing operation and controlled using IOT (Internet of Things) has been developed.

Index Terms

Drilling, Sowing, Ball bearings, Shaft, hopper, Battery.

INTRODUCTION

In current world, every process is getting automated and people are getting used to adopt smart techniques to get their work done. It can be seen that with flow of time, how seed sowing techniques and equipment's have kept on progressing. Proper seed sowing is very important part of agricultural process and for the same purpose hand operated seed sowing machine have been designed and developed. Despite agriculture being one of the most important fields for determining the growth of a country, it is lagging in terms of smart working. One of the biggest irony is agriculture being the main occupation in many countries still it lags in using the smart techniques in this field. If technology is introduced in farming techniques there are chances that ever-growing populating in the coming future might be fed adequately. To suffice such a large amount, agricultural yield must also be increased rapidly. Due to poor seed quality & inefficient farming practices, and lack of cold storage and harvest spoilage, nearly 30% of the farmer's produce is wasted. Not in just theory practically we can see how automation helps in increasing output of farming, in US, where automation techniques in agricultural farming have already been implemented the cereal yield is nearly 6600 Kg/Hectare which is three times more than in India whose cereal yield is just 2600 Kg/Hectare approximately. During the years, the machine is subjected to different design modifications with the focus on mechanical system design, to realize the objective of improving the performance in the fields. The automation of different processes involved in the seed sowing machine were also investigated, like solar powered systems, utilization of seed metering systems, use of sensors with Bluetooth modules etc., With all these information and thoughts, automation of seed sowing machine using ESP8266 wifi module, relay and step down module has been developed in this research work. The fabricated machine is very convenient and the technology used to feed command to machine is IoT which lets the user to command the machine from anywhere. This will reduce the human effort and time taken to sow same area with better and constant spacing between seeds. But these machines or attachments should be cost effective and be affordable to the farmers. Hence a less expensive, distinct machine or attachment has to be designed and developed so that it can be used for different crops and in different seasons.

LITERATURE REVIEW

This study was conducted to develop a push- type double-row carrot seeder. Specifically, the study investigated the performance of the carrot seeder at different operating speeds in terms of field efficiency, field capacity, germination, and uniformity of seed discharge. In addition, the study aimed to establish optimum operating speeds and compare the use of the device and manual sowing of carrot seeds. The device consists of a hopper, seed metering disc, soil opener, and seed coverer, grip handle, ground wheel, and power transmission; all attached to the frame. The metering disc is synchronized with the ground wheel as a source of power during operation. The design of the carrot seeder was prepared using AutoCAD software. It was fabricated using locally available materials. Three operating speeds (0.75, 1.0, and 1.25 m/s) were used during the evaluation. An area of 225 sq. m was used. It was divided into 9 plots with dimension of 50 cm by 500 cm.(T. Valentin, Published online 31 December 2016.)

Is a major vegetable crop which is a good source for human diet? Carrot planting, conventionally done by manual dibbling, is a labor intensive and thus, costly operation. The mechanization of carrot planting aims to reduce the operational costs, minimizing human drudgery and enhance the production. The appropriate crop machine and operational parameters were identified. Tractor operated prototype mechanical carrot planter was designed and evaluated for its field performance 4 using treatments viz. uncoated carrot seeds (S1), biogas slurry coated seeds (S2) and Thira me coated seeds (S3). (2018 - Indra Mani2)

To meet future food demands, it is essential to provide new technologies to the farmers. There are several processes, viz. excavation, planting, irrigation, etc. for which the farmers are still worried. Mechanization reduces the cost of labor and improves overall productivity without any effect on the quality of the soil. Hence, it is necessary to provide them with some useful economic solutions for these problems. In the present work, the problem of seed sowing has been addressed. The conventional method of seed sowing is not efficient and is time- consuming. In the present work, a multifunctional seed sowing machine has been designed, which can sow the seed and can discharge the fertilizer simultaneously. The design of the machine has been done using SolidWorks, and the analysis has been done with the help ANSYS workbench 15.0 (Gaurav Kumar-2020, 595-602, 2021)

The present review provides brief information about the various types of automatic seed sowing equipment. Agriculture forms an integral part of the Indian economy. The methodology implemented in carrying out agricultural activities as many constraints such as non-availability of labour low productivity rate, regularity due to whether constant and fatigue. To overcome this problem, we need to automate and mechanize the agriculture sector. During the Sowing operation we can carry out the other operations simultaneously so the cost will reduce and also saves time. By using the seed sowing cum fertilizer sowing and pesticides sowing machine we can do this all the operation simultaneously (Smite N Solanki)

DC MOTOR

The DC motor is the motor which converts the direct current into the mechanical work.

HOPPER

It stores the seeds to be sown in the soil. Higher the capacity less the need to refill the hopper during process.

BATTERY

A battery is a device that converts chemical energy contained within its active materials directly into electric energy by means of an electrochemical oxidation reduction reaction.

SHAFT

The term shaft usually refers to a component of circular cross section that rotates and transmits power from a driving device, such as a motor or engine, through a machine.

SEED DISTRIBUTOR

It consists of fluted rollers which are driven by rear wheel with the help of belt and pulley.

BEARING

Bearings perform the function of preventing damage from being done by this force to the part that supports the rotation, and also of maintaining the correct position of the rotating shaft.

METALFRAME

Steel framing provides excellent design flexibility due to the high strength-to-weight ratio of steel, which allows it to span over long distances.

FIXING BATTERY UNDER THE SEAT

In this figure we can see the both the fuel engine and battery coil which is perfectly assembled and clamped to the bike and fuel engine is perfectly aligned straight to back wheel.

The coil of the batteries perfectly engine mountain at the top of the rear wheel body frame which help us to rotate back wheel with the help four 12volts battery to rotate the front wheel with the support of battery charging

CHARGING OF BATTERIES

When driving a vehicle on electric motor, the stored energy in the batteries gets used up quickly. Batteries of a HEV can be charged either by solar charging or through regenerative braking.

OBJECTIVE OF THIS WORK

Automation: The primary goal is to automate the process of seed sowing to reduce the dependency on manual labour and improve overall efficiency.

Precision: The machine will incorporate advanced sensors and actuators to ensure precise seed placement, spacing, and depth, thereby optimizing seed germination and crop yield.

IoT Integration: By leveraging IoT technology, the machine will be capable of real-time monitoring, data collection, and remote-control functionalities. This will enable farmers to monitor the sowing process, receive alerts for any anomalies, and adjust settings remotely using a smartphone or computer.

Sustainability: The design will emphasize sustainable agriculture practices by minimizing seed wastage, optimizing resource utilization, and reducing environmental impact through precise seed placement and controlled seed distribution.

User-Friendly Interface: The machine will feature an intuitive user interface to simplify operation and configuration, making it accessible to farmers with varying levels of technological expertise.

Scalability and Adaptability: The system will be designed with scalability and adaptability in mind, allowing for easy integration with existing agricultural machinery and compatibility with different crop types and farming practices.

Cost-Effectiveness: The project aims to develop a cost-effective solution that offers significant benefits in terms of labour savings, crop yield improvement, and overall farm productivity, ensuring a favourable return on investment for farmers.

CONCLUSION

Hence in this project we are done the process of assembling the machines. We are done literature survey from the various journals based on the IOT and seed sowing machine right we done the normal seed sowing machine and we are going to work on electrical components of IOT with this seed sowing machine. As per the verification form the literature survey, we are collected method using for the connection of IOT with the seed sowing machine right now there is only in remote control seed machine are there but we are investigating the method for the IOT based seed sowing machine

Abstract This paper presents the concept of Multi-Function Operating Machine mainly carried out for production based industries. Industries are basically meant for Production of useful goods and services at low production cost, machinery cost and low inventory cost. Today in this world every task have been made quicker and fast due to technology advancement but this advancement also demands huge investments and expenditure, every industry desires to make high productivity rate maintaining the quality and standard of the product at low average cost. We have developed a conceptual model of a machine which would be capable of performing different operation simultaneously, and it should be economically efficient. In this machine we are actually giving drive to the main shaft to which scotch yoke mechanism is directly attached, scotch yoke mechanism is used for sawing operation. On the main shaft we have use bevel gear system for power transmission at two locations. Through bevel gear we will give drive to drilling centre and grinding centre. The model facilitate us to get the operation performed at different working centre simultaneously as it is getting drive from single power source. Objective of this model are conservation of electricity (power supply), reduction in cost associated with power usage, increase in productivity, reduced floor space.

INTRODUCTION

Bench saw also known as Table Saw is a wood working tool consisting of a circular saw blade mounted on an arbor that is driven by an electric motor either directly or by belt or gears. We use direct connection from motor to the battery push button as a medium. Although the majority of table saws are used for cutting wood, table saw can also be used for cutting sheet plastic, iron rod, aluminium sheet etc. Depth of the cut in bench saw can be varied using hand pressure applied on an aim.

In most modern table saws, the depth of the cut is varied by moving the blade up and down: the higher the blade protrudes above the table, the deeper the cut that is made in the material. In some early table saws, the blade and arbour were fixed, and the table was moved up and down to expose more or less of the blade. The angle of the cut is controlled by adjusting the angle of the blade. Some earlier saws angled the table to control the cut angle.

LITERATURE REVIEW

In this Research paper the table saw machine consists of circular saw blade. In 1977 the first patent was issued for this machine to English man, named Samuel Miller. Varying the depth of cut, and it is done by adjusting the blade Up and Down. On the top surface support is provided for the wood being cut and blades comes through table top surface. Before table saws has arbor and blade fixed in such way that depth of cut is adjusted of the blade was done by moving the table Up and Down. when the angle of blade is been adjusted it controls and full-scale production.

Adaptability to Changing Designs:

A multifunctional table saw machine's adaptability to changing designs involves modular construction, compatibility with various accessories, adjustability in settings, upgradability for future enhancements, potential software integration, user-friendly interfaces, versatility in material handling, and scalability for different project scales.

Standard features include:

Table Saw Functionality: The machine should include a standard table saw setup, which consists of a flat, level surface with a blade mounted beneath it. This allows for cutting various types of wood and other materials.

Adjustable Fence: A fence is a guide that helps to ensure straight and accurate cuts. A multifunctional table saw should have an adjustable fence that can be easily moved and locked into place at different distances from the blade.

Miter Gauge: A miter gauge helps in making angled cuts accurately. It should be included as a standard feature and should be adjustable to different angles.

Blade Guard and Riving Knife: Safety features such as a blade guard and riving knife should be included to protect the user from accidental contact with the spinning blade.

Dust Collection System: Many modern table saws include a dust collection system to minimize sawdust and debris, keeping the work area cleaner and reducing health hazards.

On/Off Switch: A convenient on/off switch should be easily accessible, allowing the user to start and stop the machine quickly and safely.

Motor: A powerful motor is essential for cutting through various materials with ease. The horsepower and voltage of the motor may vary depending on the size and intended use of the table saw.

Safety Features: Emergency stop buttons, overload protection, and blade brake mechanisms are additional safety features that may be included in a multifunctional table saw.

Versatility: Beyond basic table saw functions, a multifunctional table saw may also include features for other woodworking tasks such as routing, sanding, or shaping. These additional functions can greatly expand the capabilities of the machine.

Sturdy Construction: The table saw should be built with durable materials and designed to withstand the environment rigors of regular use in a workshop.

These are some of the standard features you might expect to find in a multifunctional table saw machine. However, specific features may vary depending on the manufacturer and model. It's always a good idea to review the specifications of a particular machine to ensure it meets your needs and expectations.

OBJECTIVE OF THIS WORK

Versatility: To offer a single machine capable of performing multiple functions such as ripping, cross-cutting, beveling, dado cutting, joinery, and possibly other operations like routing or sanding.

Precision: To enable accurate and consistent cuts, ensuring high-quality results in woodworking projects.

Efficiency: To streamline workflow and increase productivity by allowing users to perform a wide range of tasks without the need for multiple specialized tools.

Safety: To prioritize user safety through the inclusion of safety features such as blade guards, riving knives, emergency stop buttons, and ergonomic designs.

Ease of Use: To design the machine with intuitive controls, ergonomic features, and user-friendly interfaces to simplify operation and reduce the learning curve for users of all skill levels.

Adaptability: To accommodate changes in project requirements, materials, and cutting techniques by offering adjustability in settings, compatibility with various accessories, and potential for future upgrades.

Durability: To construct the machine with high-quality materials and components that can withstand the rigors of regular use in a workshop environment, ensuring longevity and reliability.

Cost-effectiveness: To provide a cost-effective solution for woodworkers by consolidating multiple functions into a single machine, thereby reducing the need for additional equipment purchases.

By fulfilling these objectives, a multifunctional table saw machine aims to enhance the capabilities and efficiency of woodworking operations while prioritizing safety, precision, and user satisfaction.

Breakout Multifunctional Table Saw Machine

Table Saw Functionality: At its core, the machine operates as a table saw, featuring a flat surface with an integrated saw blade that can be adjusted in height and angle. This allows for precise rip cuts, crosscuts, bevel cuts, and more.

Miter Saw Capability: Many multifunctional table saw machines include a miter gauge or miter saw attachment. This enables the user to make angled cuts accurately, typically up to 45 degrees.

Router Table Attachment: Some models come with a router table attachment or the ability to convert into a router table. This allows for tasks such as edge profiling, slot cutting, and dadoing.

Planer Attachment: Certain multifunctional table saw machines may offer a planer attachment, allowing users to flatten and smooth wood surfaces to a desired thickness.

Jointer Attachment: For woodworking tasks requiring edge jointing, some models feature a jointer attachment. This enables users to create straight and true edges for joining wood pieces together.

Drill Press Functionality: Some multifunctional table saw machines can also function as a drill press. This adds versatility to the machine, allowing for precise drilling of holes in wood pieces.

Dust Collection System: Many modern machines come equipped with a dust collection system to keep the work area clean and minimize airborne dust particles.

Safety Features: Safety is paramount when working with power tools. Multifunctional table saw machines often include safety features such as blade guards, riving knives, and emergency stop switches to prevent accidents.

Portability and Space-saving Design: Depending on the model, some machines are designed to be portable or feature a compact design, making them suitable for smaller workshops or job sites where space is limited.

Customization and Add-on Compatibility: Users may have the option to customize their machine with various add-ons and accessories, enhancing its functionality for specific woodworking tasks.

Overall, a breakout multifunctional table saw machine offers woodworkers a comprehensive tool for a wide range of cutting, shaping, and woodworking tasks, consolidating multiple tools into a single, space-saving unit. However, it's essential to carefully review the features and specifications of different models to ensure they meet your specific woodworking needs and preferences.

CONCLUSION

In conclusion, the multifunctional table saw machine represents a versatile and efficient solution for woodworkers of all skill levels. By integrating multiple functions into a single unit, these machines offer a space-saving and cost-effective alternative to purchasing individual tools for each woodworking task.

With features such as table saw functionality for precise cuts, miter saw capability for angled cuts, router table attachments for shaping edges, and various other functionalities like planing, jointing, and drilling, these machines empower users to tackle a wide range of woodworking projects with ease and precision.

Furthermore, modern multifunctional table saw machines prioritize safety with built-in features such as blade guards, riving knives, and emergency stop switches, ensuring a secure working environment for users.

Whether you're a hobbyist working in a small workshop or a professional on a job site, a multifunctional table saw machine offers the flexibility, convenience, and performance needed to bring your woodworking projects to life efficiently and effectively.

Abstract

The automotive industry faces significant hurdles due to dwindling fossil fuel resources and increasing pollution levels. To overcome these challenges, there's a pressing need for alternative fuel sources. While electric vehicles offer a promising solution, transitioning existing heavy vehicles poses a significant challenge. This project aims to address these obstacles by introducing a novel supporting fuel with minimal emissions. Hydroxy (HHO) Gas, derived from electrolyzing water with a catalyst like KOH, offers three times the potency of petrol. It serves as a complementary fuel for diesel engines, promoting complete combustion and reducing fuel consumption.

INTRODUCTION

As humanity's reliance on energy grows, there's an ongoing pursuit for more efficient energy conversion methods. Traditionally, power generation has heavily relied on wood, coal, and petroleum, but their finite nature demands exploration into alternative sources. Enter renewable energy, a burgeoning field driven by the need for sustainable solutions. While natural gas and coal have been touted as interim alternatives, their classification as fossil fuels underscores their limited sustainability. Consequently, the quest for renewable energy sources intensifies, urging researchers to delve deeper into nature's offerings to meet future energy demands.

Among the array of alternative energy sources lie solar energy, hydroelectric power, and biomass energy. Hydrogen energy stands out as a particularly promising avenue due to

hydrogen's abundant presence, albeit in compound form, on Earth. Hydrogen's versatility allows it to seamlessly replace hydrocarbon fuels without necessitating extensive alterations to existing machinery, while its combustion results in minimal emissions. To harness hydrogen as a fuel, electrolysis emerges as a pivotal process, facilitated by an electrolyzer or hydrogen generator. This machine splits water molecules into hydrogen and oxygen, yielding brown gas, also known as HHO gas. Electrolysis, a method of breaking molecules into their elemental components through electrical current, transforms water molecules back to their base elements. The use of a base solution like KOH in electrolysis initiates an alkaline reaction, prompting the reduction of water molecules into hydrogen gas and OH⁻ anions at the cathode. The resulting hydrogen gas, colorless and highly flammable, exhibits properties conducive to efficient energy production. However, HHO gas typically requires an external ignition source to ignite. Enhancing the efficiency of electrolysis equipment involves optimizing electrode surface area to minimize electrical current requirements. In this research, stainless steel 316 L electrodes and KOH solution serve as the electrode and electrolyte, respectively, contributing to the advancement of electrolysis technology.

When preparing electrolysis equipment, careful attention must be paid to the surface area of the electrodes to prevent excessive current flow, which could lead to overheating. Flow meter measurements will be utilized to quantify the gas output produced by the generator, while gas chromatography will be employed to analyze its composition. These measurements serve to determine the volume of HHO gas generated and assess the efficiency of the electrical current utilized in the equipment.

BROWN'S GAS (HHO GAS)

Brown's gas, also known as HHO gas, comprises a combination of hydrogen and oxygen gases in a 2:1 atomic ratio, mirroring the composition of water. When heated to its auto-ignition temperature of around 570°C (1065°F), oxy-hydrogen undergoes combustion, generating energy and transforming into water vapor. This energy sustains the reaction, facilitating continuous combustion. Under standard temperature and pressure conditions, oxyhydrogen can ignite and burn effectively when its hydrogen content ranges between approximately 4% and 95% by volume.

Through the process of water electrolysis, a perfectly balanced stoichiometric mixture can be achieved by utilizing an electric current to split water molecules:

Electrolysis: $2 \text{H}_2\text{O} \rightarrow 2 \text{H}_2 + \text{O}_2$

Combustion: $2 \text{H}_2 + \text{O}_2 \rightarrow 2 \text{H}_2\text{O}$

William Nicholson pioneered the technique of decomposing water in this fashion back in 1800. However, it's important to note that the energy needed to produce oxy-hydrogen through this method always surpasses the energy yielded from its combustion.

DIFFERENCE BETWEEN HHO GAS AND HYDROGEN

HHO gas, unlike pure hydrogen, contains an optimal ratio of one part oxygen to two parts hydrogen, making it significantly more combustible. Its economic advantage lies in its ease of production from water, making it a cost-effective option. This has led to its recognition as a potent combustion enhancer, with some researchers exploring the possibility of developing vehicles that run entirely on HHO gas generated onboard from water. While this prospect holds promise for environmental benefits, it poses a potential threat to the dominance of oil companies, as widespread adoption of nearly free and clean energy could shift global economic power significantly. The efficiency of HHO gas production is highlighted by the fact that one kilowatt-hour of electricity yields approximately 340 liters of gas, with the production volume easily scalable. Moreover, upon ignition, HHO gas undergoes implosion, resulting in a vacuum effect that further emphasizes its energy efficiency. With one unit of water yielding 1,860 units of gas, the potential for efficient energy utilization is evident. Comparatively, Brown's Gas, with its higher atomic form, requires less energy to burn than the $\text{H}_2:\text{O}_2$ gas mixture, resulting in lower combustion temperatures and increased vehicle efficiency.

METHODOLOGY

In previous research, researchers used the HHO calculator program as shown, published by David Biggs to collect information about how to decide cell configuration and how much gas can be produced.

FUNCTIONAL DESIGN APPROACH

This hydrogen generator operates through a series of chambers and components, each serving a specific function. Firstly, there's the Feed Chamber, acting as a reservoir for the electrolyte feed water, capable of holding up to 5 liters. Beneath it, a safety valve ensures

precautions in case of feed water issues or overload situations. The core of the generator is the reactor where electrolysis occurs. Here, electrodes facilitate the decomposition of water molecules into hydrogen (H_2) and oxygen (O_2), with one electrode functioning as a cathode (+) and the other as an anode (-). During electrolysis, positive ions migrate towards the anode while negative ions move towards the cathode. To regulate the flow of HHO gas optimally, a check valve is incorporated into the equipment, allowing or blocking gas flow as necessary. Initially closed for a minute during startup, the valve is later opened to discharge the gas. A power supply provides the necessary electricity through the electrodes, with a PWM (Pulse Width Modulation) module ensuring synchronized electric current from the source. The gas produced from electrolysis is then directed into a Bubbler Tube, where it undergoes purification using water as the medium. This tube includes a one-way valve to prevent reverse gas flow. After purification, the gas passes through a safety arrestor to prevent explosions during gas burning. Additionally, a Flow rate Transmitter measures the speed and volume of the resulting HHO gas flow. Finally, the purified gas is directed through a nozzle for direct burning, allowing it to be used as an alternative energy source.

STRUCTURAL DESIGN APPROACH

The electrolysis reactor, a crucial component of the hydrogen generator, is meticulously crafted for efficient hydrogen production. Constructed from an acrylic tube measuring 40 cm in height and 20 cm in diameter, it boasts auxiliary chambers, including a 5-liter feed chamber positioned atop the hydrogen reactor. This feed chamber serves as a reservoir for electrolyte feed water and is intricately designed to fit snugly within the reactor's casing. Within the reactor, 42 cathodes and anodes, crafted from stainless steel, are strategically placed. Each electrode measures 6 cm in width and 11 cm in length, contributing to the electrolysis process. The electrode configuration, determined using an HHO calculator, comprises six stacks of stainless-steel plates with seven cathodes and anodes connected in parallel. Notably, type 316 L stainless steel is chosen for its durability and effectiveness in this research endeavor. At the gas output, a hose facilitates the seamless connection to the Bubbler Tube, also fashioned from acrylic material and matching the dimensions of the reactor. Equipped with a flow rate transmitter and check valve, the Bubbler Tube ensures the efficient purification of generated gas. A closure, affixed to the upper part of the tube, is

connected to a hose and furnished with a bypass valve, allowing precise control over gas flow, whether directed to the flow rate transmitter or the Arrestor-Nozzle. Safety remains paramount, with the hose outfitted with a safety arrestor to mitigate the risk of flashback incidents. To further fortify safety measures, an 80 cm wide and 60 cm high Fiber Board Buffer is ingeniously designed to serve as a protective buffer frame for the integrated hydrogen generator.

CONSTRUCTION

The automotive industry has recently embraced Brown's gas (HHO) as a promising alternative energy source. This study proposes the design and integration of a compact HHO-generating device within the engine compartment of gasoline engines. Through meticulous design, construction, integration, and testing, this auxiliary device aims to significantly enhance engine performance. The optimal surface area of the electrolyte required for HHO generation is determined to be twenty times that of the piston surface area, while the water volume in the cell should be about one and a half times the engine capacity. The primary objectives of this integration are to achieve a substantial reduction in fuel consumption (around 20–30%), lower exhaust temperatures, and subsequently mitigate pollution emissions. By injecting Brown's gas into the air intake manifold as a supplemental fuel, the combustion process is expedited, promoting more efficient utilization of vaporized fuel during the power stroke. Notably, HHO gas exhibits rapid and clean combustion within internal combustion engines, yielding water as the sole byproduct, thereby curbing emissions, and reducing environmental impact. Safety measures, including water bubbler bottle systems and pressure valves, ensure the safe operation of the HHO system, minimizing the risk of explosions. Moreover, the convenience of on-demand HHO production eliminates the need for dedicated filling stations or extensive infrastructures, requiring only water as a resource. While the concept behind the HHO generator aims to enhance engine efficiency by increasing the speed of the flame front through hydrogen concentration, it's crucial to recognize that without altering the fixed compression ratio of the engine, efficiency gains may be limited.

COMPONENTS

WARESERVOIROIER

An oxy-hydrogen generator, known by various names such as brown gas generator, acrylic polishing machine, water welding machine, or HHO gas generator, operates by electrolyzing clean, soft water (H_2O) to produce hydrogen and oxygen gases using minimal electric power. These generators are designed to be user-friendly and safe, offering a range of gas flows and flame powers to suit different needs, from individual users to factory-level operations. Applications for the generated gases are diverse, including acrylic polishing, glass tube sealing, ampoule sealing, mold repair, solar wafer processing, IC packaging, various metal welding tasks (platinum, gold, silver, copper, stainless steel), electric motor brazing, LED wafer treatment, circuit board welding, dentistry (mending sand holes, etc.), and welding storage battery tinplate, among others. Hydrogen is hailed as one of the cleanest and most environmentally friendly fuel gases available, positioning it as a crucial component in the shift towards environmentally sustainable energy solutions in the 21st century.

BUBBLER

The bubbler is purely a special one-way valve device to help prevent any possible damage to the HHO generator or other components in case of an engine backfire causing back-flash. There is no reaction between the water and the HHO gas passing through it. Keep the bubbler lower than the reservoir and lower than the gas entry point to the air intake. This

way, the liquid remains in the bubbler and cannot reenter the reservoir or be sucked into the air intake. It also remains in the bubbler itself, therefore fulfilling its function.

CALL

An electrolyzer serves as a vital scientific apparatus utilized to break down polarized molecules into their constituent ions. Specifically, in the context of water electrolysis, an electrolyzer facilitates the separation of water molecules into hydrogen and oxygen gas through an electrochemical process. Two common types of electrolyzers exist: dry cells and wet cell. The dry cell electrolyzer is fully enclosed, ensuring the separation of gases occurs within a controlled environment. On the other hand, the wet cell electrolyzer typically involves two metal plates submerged in a bowl of water, allowing for the electrolysis process to take place in an open system. While the equipment itself may appear straightforward, comprehending the underlying theoretical principles governing electrolysis can be more complex.

The electrolyzer functions by leveraging the distinct ionic charges present within the molecules to effectively split them into their corresponding charged atoms or molecules. For instance, in the case of water molecule dissociation, the slightly positive charge on the hydrogen atoms and the slightly negative charge on the oxygen atom facilitate their separation. These charges, albeit very subtle, typically amount to around +1 electron volt (eV) for each hydrogen atom and -2 eV for each oxygen atom. To put this into perspective, 1 eV equates to approximately 1.6×10^{-19} Coulombs (C), with 1 Coulomb representing the charge transported by a steady current of one ampere in one second. As a result of these charges, hydrogen ions are attracted to the negatively charged cathode, while oxygen ions are drawn towards the positively charged anodes. At the anodes, oxygen ions release an electron and bond to form oxygen gas, whereas at the cathodes, hydrogen ions gain an electron from the cathode and bond to form hydrogen gas. This electron transfer to and from the electrodes completes the circuit, facilitating the flow of current. Employing a catalyst can enhance the efficiency of the electrolysis process by reducing the energy required to initiate it. In this context, sodium hydroxide serves as a catalyst, typically mixed in a ratio of 1 to 40 with deionized water. While deionized water isn't strictly necessary, its use extends the lifespan of the unit by preventing mineral buildup and other deposits on the electrodes.

HHO IN IC ENGINE

FUNCTION

To address the limitations of hydrogen produced through conventional electrolysis methods, Brown developed a specialized electrolysis technique implemented in the Brown Gas Generator. This generator utilizes a parallel plate electrolyzer where the process parameters such as temperature, pressure, and duration are carefully controlled based on extensive research findings, ensuring optimal performance. During electrolysis, water molecules are split into oxygen and hydrogen, resulting in the formation of a milky white solution. This solution is then directed to a separator unit where Brown Gas is separated from water. The water is subsequently recycled back into the electrolysis device for further use. Brown Gas, distinct from a mere mixture of hydrogen and oxygen, with a fixed 2:1 ratio respectively, is channeled into the engine through the intake manifold without disrupting fuel injection systems. This innovative approach allows vehicles to utilize water as well as petroleum, depending on demand, with Brown Gas proving to be a sufficient fuel source for engine operation. The specialized electrolysis technique employed in the Brown Gas Generator represents a significant advancement in gas production, offering an efficient and reliable method for generating this unique gas mixture.

EFFICIENCY

Water electrolysis, despite its potential for generating hydrogen as a clean energy source, faces inherent inefficiencies. Notably, the process does not achieve 100% conversion of electrical energy into the chemical energy of hydrogen due to various forms of overpotential.

This excess potential, primarily attributed to the reaction at the anode involving the oxidation of water to oxygen, results in energy loss primarily in the form of heat. One of the critical challenges lies in the lack of an effective electrocatalyst to facilitate this reaction efficiently. Additionally, the reverse reaction, involving the reduction of oxygen to water at the cathode, contributes significantly to efficiency loss, particularly in fuel cells. The development of cost-effective and efficient electrocatalysts for these reactions represents a significant area for advancement. The energy efficiency of water electrolysis varies considerably, with reported values ranging from 50% to 80% efficiency in converting electrical energy into hydrogen's chemical energy. However, it's important to note that these figures typically exclude the energy lost in generating the electricity itself. For instance, in scenarios like power plants utilizing nuclear reactions to generate heat for electrolysis, the overall efficiency may be closer to 30–45%, highlighting the complexity and challenges associated with achieving high-efficiency hydrogen production.

COMBUSTION AND AIR/FUEL RATIO

Gasoline from the fuel tank undergoes a process where it's atomized into tiny droplets, mingling with atmospheric oxygen, before being drawn into the engine cylinders via vacuum or fuel injection systems. Inside the cylinder, the piston compresses this mixture, and upon ignition by the spark plug, combustion occurs, supplying power to propel the vehicle. An essential factor influencing the efficiency of this combustion process is the air/fuel ratio, dictating the balance between fuel and air. A lean mixture, with too much air or too little fuel, may lead to reduced power output due to insufficient fuel for combustion. Conversely, a rich mixture, with excessive fuel or inadequate air, can also result in power loss as there's insufficient oxygen to burn all the fuel effectively. Additionally, a rich condition leads to fuel wastage, as unburned fuel is expelled through the exhaust. Historically, car manufacturers have tuned the air/fuel ratio to optimize power while leaning towards the rich side to accommodate fluctuations in atmospheric conditions. This practice ensures a smooth and consistent power delivery across various operating conditions. However, the unburned fuel resulting from this rich ratio setting is still disposed of through exhaust-mandated emission controls like catalytic converters, highlighting the significant amount of fuel wasted as a precaution against power loss due to environmental changes during travel.

FUEL CONFIGURATION

The configuration of fuel plays a significant role in combustion efficiency, influencing how effectively the fuel is utilized during the combustion process. Fuel configuration refers to the size of fuel units, with smaller units resulting in faster and more complete combustion reactions. When the fuel-air mixture ignites in the cylinder, the resulting exothermic reaction spreads outwards from the spark plug in the form of a flame front or wave. Each droplet of gasoline ignites sequentially, with the heat generated by neighboring droplets sustaining the reaction if oxygen is available. However, only the surface of the droplet burns initially, as it's in direct contact with the oxygen in the cylinder. The interior of the droplet must wait for the reaction to reach it, like a charcoal briquette burning from the outside. Meanwhile, as the reaction progresses around the sides of the droplet where oxygen is present, neighboring droplets are heated and ignited, propagating the flame front. The size of the droplet ultimately determines whether it burns completely or not, with larger droplets requiring more time to burn due to their increased volume.

The size of fuel units not only affects combustion efficiency but also impacts the velocity of the flame front. Larger fuel units result in slower flame propagation due to the increased time required for neighboring droplets to reach their ignition points, known as ignition propagation delay. To illustrate this concept, consider the analogy of throwing a piece of coal onto a campfire versus tossing crushed coal powder into the flames. The piece of coal takes longer to ignite and burn completely, whereas the crushed powder ignites almost instantaneously due to its increased surface area, exposing more fuel to oxygen for combustion. This rapid ignition and burning of the powder demonstrate how fuel configuration influences combustion dynamics. Smaller fuel units burn faster, collectively generating higher temperatures, and accelerating flame propagation. While gasoline droplets in engine cylinders function differently from coal, they adhere to the same principles of combustion. Larger droplets take longer to burn completely, whereas smaller droplets burn more rapidly and thoroughly, contributing to enhanced combustion efficiency.

ENTER HHO

HHO, or Brown's gas, exhibits remarkable efficiency in terms of fuel configuration. This unique gas mixture consists of hydrogen and oxygen atoms arranged in tiny, independent

clusters, with each cluster containing no more than two atoms, forming diatomic molecules of H_2 and O_2 . This configuration enhances the combustion properties of HHO, as the small and discrete clusters facilitate rapid and thorough combustion when introduced into the engine's combustion chamber. The presence of these tiny clusters ensures that the fuel is readily available for combustion, maximizing energy release and contributing to improved overall combustion efficiency. Thus, HHO emerges as a promising fuel option due to its highly efficient fuel configuration, offering potential benefits in various applications requiring clean and efficient energy sources.

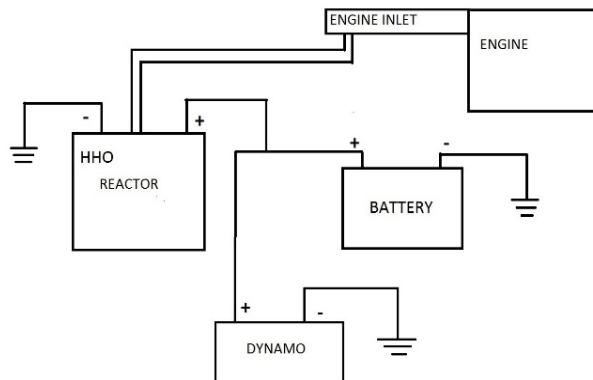

In contrast to the small and discrete clusters of hydrogen and oxygen atoms found in HHO, a gasoline droplet is considerably larger, consisting of many thousands of large hydrocarbon molecules. This difference in configuration highlights the efficiency of HHO combustion. The diatomic configuration of HHO enables direct interaction between hydrogen (H_2) and oxygen (O_2) molecules, eliminating any ignition propagation delays caused by surface travel time of the reaction. This direct interaction ensures swift and efficient combustion, as each H_2 molecule reacts immediately with an O_2 molecule, leading to rapid energy release. As a result, HHO combustion offers distinct advantages over gasoline combustion, presenting a highly efficient and effective fuel option for various applications.

The combustion dynamics of HHO differ significantly from those of a gasoline/air-fuel mixture. Unlike gasoline droplets, which can form large globes that burn slowly from one side to the other, HHO's ignition propagation is immediate and direct, occurring atom to atom. When HHO is combined with the gasoline/air fuel mixture, its hydrogen surrounds the gasoline droplets. Upon ignition, the flame front of HHO travels through the cylinder at a much higher velocity compared to ordinary gasoline/air combustion. This intense heat and pressure wave generated by HHO crushes and fragments the gasoline droplets, exposing fuel from their interior to oxygen and the combustion reaction. Consequently, this process effectively enriches the air/fuel ratio, as more fuel becomes available for combustion. Additionally, the HHO flame front ignites the crushed fragments rapidly, releasing more energy from the fuel in a shorter period. Like crushed coal powder liberating its energy faster than a single large piece, the dispersion of HHO throughout the cylinder accelerates the combustion process. As a result, the gasoline/air mixture no longer

undergoes a slow, sequential droplet-to-droplet ignition process. Instead, HHO detonates all the "crushed" fuel virtually simultaneously, acting as an explosive primer. This leads to increased pressure on the piston within a shorter time interval, contributing to enhanced engine performance and efficiency.

A critical advantage of the combustion process facilitated by HHO is its ability to extract power from fuel that would have otherwise been wasted and expelled with the exhaust. Specifically, the fragmentation of droplets induced by HHO results in a greater availability of gasoline or diesel fuel for combustion, effectively maximizing the conversion of fuel into power without requiring additional fuel from the gas tank. This means that the engine can derive more energy from the existing fuel supply, enhancing fuel efficiency and overall performance. By utilizing HHO, engines can optimize the utilization of fuel resources, minimizing waste and maximizing power output without increasing fuel consumption.

As a result of its combustion-enhancing properties, HHO significantly improves gas mileage by promoting more efficient and complete burning of gasoline in the engine, thereby extracting more work from each gallon of fuel consumed. The presence of HHO in the cylinders leads to increased droplet fragmentation, resulting in higher combustion efficiency. It's recommended to utilize volume generators operating below 20 amps, as generators exceeding this threshold may begin to produce steam instead of HHO gas. Installing an HHO system in a vehicle with generators exceeding 20 amps can strain the alternator, compromising the quality of the generated HHO gas and subsequently affecting fuel mileage. The process of extracting HHO gas from water is greatly enhanced with the use of electrolytes, further optimizing the efficiency of the electrolysis process. By employing HHO technology, vehicles can achieve improved fuel economy and enhanced engine performance, contributing to overall cost savings and reduced environmental impact.

WATER USED IN HHO SYSTEM

If we drive an average of about 3,000 miles a month is enough for 1 liter of distilled water. Which is Very little? And water is a free source of Hydrogen, so it is cheaper than any other.

CONCLUSION

In conclusion, the implementation of HHO technology results in a more thorough combustion process while simultaneously reducing the combustion speed. This leads to minimized heat loss through the engine and cylinders, ultimately translating into improved fuel economy with significantly reduced emissions. By utilizing HHO gas, engines require less fuel to generate equivalent power output, contributing to overall efficiency gains. Furthermore, the combustion facilitated by HHO leads to reductions in hydrocarbon (HC) and carbon dioxide emissions, while a larger percentage of particulate matter is effectively consumed and converted into energy. As a result, emissions are decreased, and engine efficiency is enhanced, underscoring the potential of HHO technology to drive cleaner and more sustainable transportation solutions.

ABSTRACT

Need of new materials is always important in industries, better mechanical properties and lower in cost are the main parameters which attracts everyone to develop a new material. This need arises in the form of composite materials. This paper reviews about the composites, their existence, fabrication and testing of metal matrix and the characterization of metal matrix composites. Different fabrication techniques were mentioned which can be used for the manufacturing of metal matrix composites but specially focused on stir casting.

KEYWORDS

MMC – Metal Matrix Composites

AMC – Aluminium Matrix Composites

INTRODUCTION

In a stir casting process, the reinforcing phases are distributed into molten matrix by mechanical stirring. Stir casting of metal matrix composites was initiated in 1968, when S. Ray introduced alumina particles into an aluminium melt by stirring molten aluminium alloys containing the ceramic powders. Mechanical stirring in the furnace is a key element of this process. The resultant molten alloy, with ceramic particles, can then be used for die casting, permanent mould casting, or sand casting.

An interesting recent development in stir casting is a two-step mixing process. In this process, the matrix material is heated to above its liquids temperature so that the metal is totally melted. The melt is then cooled down to a temperature between the liquids and

solidus points and kept in a semi-solid state. For making the frame we have used nut and bolt join so that we can easily change the dimensions as per the requirement so we did drilling as per the dimension. The cast composites are sometimes further extruded to reduce porosity, refine the microstructure, and homogenize the distribution of the reinforcement. A major concern associated with the stir casting process is the segregation of reinforcing particles which is caused by the surfacing or settling of the reinforcement particles during the melting and casting processes. The final distribution of the particles in the solid depends on material properties and process parameters such as the wet condition of the particles with the melt, strength of mixing, relative density, and rate of solidification.

There are different routes by which MMCs may be manufactured, and among all the liquid-state processes, stir casting technology is considered to have the most potential for engineering applications in terms of production capacity and cost efficiency. Casting techniques are economical, easier to apply and more convenient for mass production. In preparing metal matrix composites by stir casting method some of the factors that need considerable attention are as follows,

- To achieve uniform distribution of the reinforcement material.
- To achieve wettability between the two main substances.
- To minimize porosity in the cast metal matrix composite.

LITERATURE REVIEW

This review aims to explore the fundamental mechanical and tribological behavior, Aluminum matrix composites (AMCs) reinforced with different reinforcements. Aluminum matrix composites are considered to be the new emerging class of materials which are having the tailored properties for specific applications. AMCs are the advanced engineering materials having superior properties as comparison to other conventional aluminum alloys. AMCs exhibits attractive properties such as high hardness, better yield strength, strength to weight ratio, high thermal conductivity, low coefficient of thermal expansion, superior wear and corrosion resistance. In recent times, because of these properties they have revealed keen interest for various potential applications in aerospace, automotive and various other structural applications. Extensive research and development has been made in the Al-based

MMCs with every possible alloy and different reinforcements so as to get the material of desired properties.

PROBLEM SOLVING

Generally, stir casting process plays major role in case of Metal Matrix Composites (MMC) for attaining better mechanical properties. So, the aim is to find a solution to the above problem by Fabrication and Testing of MMC (Metal Matrix Composites) made by casting done on our previously designed and fabricated experimental setup of Stir Casting Machine.

EXPERIMENTAL SETUP

STIR CASTING METHOD

Stir design is very important parameter in stir casting process which is required for vortex formation. The blade angle and number of blades decides the flow pattern of the liquid metal. The stirrer is immersed till two third depth of molten metal. All these are required for uniform distribution of reinforcement in liquid metal, perfect interface bonding and to avoid clustering. Stirring speed is an important parameter to promote binding between matrix and Reinforcement i.e. wettability. Stirring speed decides formation of vortex which is responsible for dispersion of particulates in liquid metal. In our project stirring speed is around 300 rpm. Aluminium melts around 650°C , at this temperature semisolid stage of melt is present. Particle distribution depends on change in viscosity. The viscosity of matrix is mainly influenced by the processing temperature. The viscosity of liquid is decreased by increasing processing temperature with increasing holding time for stirring which also promote binding between matrix and reinforcement. Good wettability is obtained by keeping temperature at 800°C . As stirring promote uniform distribution of reinforcement particles and interface bond between matrix and reinforcement, stirring time plays a vital role in stir casting method. Less stirring leads to non-uniform distribution of particles and excess stirring forms clustering of particles at some places. Stirring time is 5 minutes in our case.

Casting process of MMC's is difficult due to very low wettability of alumina particles and agglomeration phenomenon which results in non-uniform distribution and poor mechanical properties. Reinforcement is heated to 500°C for 40 minutes. It removes moisture as well as

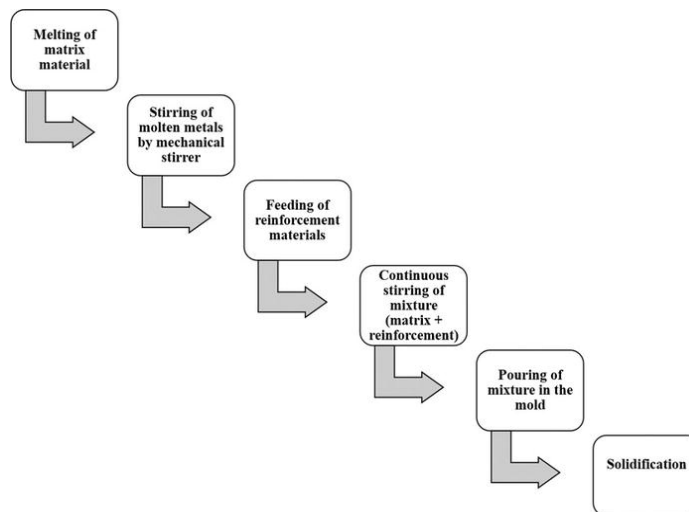

gases present in - 10 - reinforcement. The flow rate of reinforcements should be 0.5 gram per second. Pouring rate and pouring temperature plays rate of slurry must be uniform to avoid entrapping of gases. At this stage the melt is 800°C. The distance between mould and crucible casting must be less. In this paper we briefly explain preparation of the stir casting setup for alloy and composite specimen preparation. Since stir casting being economical, simple, time saving and it is having more significance than other casting process. With the help of stir casting process it is proved to manufacture castings in large quantities which is not quite possible in other casting process which are used to produce MMCs.

OPERATION

An induction furnace consists of a nonconductive crucible holding the charge of metal to be melted, surrounded by a coil of copper wire. A powerful alternating current flows through the wire. The coil creates a rapidly reversing magnetic field that penetrates the metal. The magnetic field induces eddy currents, circular electric currents, inside the metal, by electromagnetic induction. The eddy currents, flowing through the electrical resistance of the bulk metal, heat it by Joule heating. In ferromagnetic materials like iron, the material may also be heated by magnetic hysteresis, the reversal of the molecular magnetic dipoles in the metal. Once melted, the eddy currents cause vigorous stirring of the melt, assuring good mixing.

FABRICATON

Machine fabrication is a value-added process that involves the construction of machines and structures from various raw materials. The process of fabrication started in the machine shop on the basis of engineering drawings and the availabilities of the shop with respect to machining (facing, drilling, knurling, plain and step turning, welding, etc.).

ASSEMBLY OF COMPONENTS

Assembly of components is the process of combining the part or subassemblies to form the final product. Individual parts or subassemblies act as a single unit. For example, a single-part base plate and a multipart air cylinder subassembly are both components when placed in an assembly. The behaviour and characteristics of a component depend on how it was created. The principles of assembly are as follows:

- Place the pulley and stirrer rod in sequence of operation such that the mixing take place at required rpm.
- Fix the rod by using Plummer block bearings to minimize the vibration and fluctuation.
- Fix the Motor in the base frame and balance it with respect to pulley and belt.

ALUMINIUM 8011

8011 aluminum alloy is a non-heat-treatable, common aluminum foil alloy with iron and silicon as the main alloying elements. It is widely used in the packaging industry due to its excellent deep drawing performance, low earing rate, good corrosion resistance, high reflectivity, and good heat and light insulation properties. Alloys in the 8000 series having industrial applications are –

- Grade 8006 (1.5% Fe, 0.5% Mn)
- Grade 8009 (8.6% Fe, 1.8% Si, 1.3% V)
- Grade 8011 (0.7% Fe, 0.6% Si)
- Grade 8014 (1.4% Fe, 0.4% Mn)
- Grade 8019 (8.3% Fe, 4.0% Ce, 0.2% O)
- Grade 8030 (0.5% Fe, 0.2% Cu)
- Grade 8176 (0.6% Fe, 0.1% Si)

Iron (Fe), Silicon (Si), and Manganese (Mn) are the major impurities for most compositions. Some alloys have Vanadium (V), Cerium (Ce), and Copper (Cu) as the major impurities. Minor impurities are also present in some of the less-used grade 8xxx alloys. Titanium (Ti), Magnesium (Mg), Chromium (Cr), Lithium (Li), Zinc (Zn), and Zirconium (Zr) can be found.

TESTING METHODS

Among the hundreds of test methods Touchstone has used to characterized metal matrix composites, TRL has performed virtually all the tests under the Consortium Testing Specification (CTS) for the NASP (National Aero Space Plane) Materials & Structures Augmentation Program. Publication of these test methods is restricted so they are not described here. The following is a list of the NASP standard tests with which Touchstone has experience.

MECHANICAL AND PHYSICAL TESTING

The characterization of composites for mechanical properties is very important from a design and analysis as well as a life prediction point of view. The mechanical and physical testing of polymers and their composites is vital to determine the material properties for use in the design and analysis of the product, quality control, application performance requirements, and production process. The mechanical and physical testing ensure the material complies with performance requirements. Mechanical testing of composites includes tensile (tension), flexural, impact, shear, and compression, and physical testing includes water absorption, density, void content, hardness, and scratch resistance. Besides these, many other standardized bearing strength tests as per ASTM D 5961 and interlaminar fracture toughness tests to ASTM D 5538 are reported as mechanical tests on composites.

Tensile test:

Tensile testing is a destructive test process that provides information about the tensile strength, yield strength, and ductility of the metallic material. It measures the force required to break a composite or plastic specimen and the extent to which the specimen stretches or elongates to that breaking point. Tensile testing of composites is generally in the form of basic tension or flat-sandwich tension testing in accordance with standards such as ISO 527-4, ISO 527-5, ASTM D 638, ASTM D 3039, and ASTM C 297. The test specimen is prepared in accordance with standards applicable for the testing (Specimen shown below in images A and B) and subjected to tensile load with the help of a Universal testing machine. Such tests produce stress-strain diagrams used to determine tensile modulus. Tensile testing also provides tensile strength (at yield and at break), tensile modulus, tensile strain, elongation, and percent elongation at yield, elongation, and elongation at break in percentage.

Impact test:

The impact test is designed to determine how a specimen of a known material such as polymers, ceramics, and composites will respond to a suddenly applied stress. The impact test is explicitly used for evaluating the toughness, brittleness, notch sensitivity, and impact strength of engineering materials to resist high-rate loading. The ability to quantify the impact property is a great advantage in product liability and safety. Impact test specimen types include notch configurations such as V-notch and U-notch. Impact testing most commonly consists of Charpy and Izod specimen configurations.

The Izod impact test differs from the Charpy impact test in the way that the notch is positioned facing the striker. ASTM D256, ISO 180, and ASTM D are some of the standards for pendulum impact testing. In this test, a specimen is machined to a square or round section, with either one, two, or three notches. The Izod impact test consists of a pendulum with a determined weight at the end of its arm swinging down and striking the specimen while it is held securely in a vertical position. The impact strength is determined by the loss of energy of the pendulum as determined by precisely measuring the loss of height in the pendulum's swing. Also, the impact strength is defined as the tendency of polymer composites to endure high-energy impact without breaking or fracturing. It is being reported that in fiber-reinforced polymer composites and hybrid composites the impact properties are governed by the properties of the individual fibers used for hybridization, interlaminar, and interfacial adhesion between the fiber and the matrix.

Hardness test:

A hardness test is Performed on materials to check resistance to indentation. Different Hardness testing practices are used on composite materials like:

- Rockwell hardness
- Shore hardness
- Barcol hardness

Apart from the above described mechanical properties, some physical properties are also evaluated to understand the behavior of composite material. 1.Water/ moisture absorption test: To evaluate the percentage of moisture or water absorbed by the material. ASTM D 570 is the standard practice for this test. 2.Resin content or fiber content: To evaluate the Percentage of Fiber/Reinforcement or Percentage of Matrix in composite product. 3.Density Measurement: Density and specific gravity of material is evaluated as per ASTM D 792

CONCLUSION

In our paper we mainly concentrate on Testing and analysis the strength of the metal from the the casting of Metal Matrix Composites for composite materials manufacturing. SiC reinforced Al MMCs have higher.. wear resistance than Al₂O₃ reinforced MMC. The optimum conditions for fabricating Al₂O₃ reinforced Al MMC as pouring temperature-700

C, pre- heated mould temperature-550 C, the stirring speed-900 rev/min, particle addition rate-5g/min, the stirring time - 5 min and the applied pressure was 6 MPa.

Abstract

Additive manufacturing, particularly through 3D printing, has revolutionized the production of lightweight components with a variety of materials. Among these, Polylactic Acid (PLA) stands out as a widely used thermoplastic due to its biodegradability, affordability, and ease of use. However, achieving desired mechanical properties, such as hardness, in 3D printed PLA remains a challenge, often due to surface irregularities and layer adhesion issues inherent in the printing process. This study investigates the influence of surface treatments on the hardness properties of 3D printed lightweight PLA components. Through a series of experiments, specimens with different surface finishes, including as-printed, polished, sandblasted, and chemical treated surfaces, are fabricated and evaluated using standardized hardness tests. The results reveal significant variations in hardness values corresponding to different surface treatments. While the as-printed surfaces exhibit relatively lower hardness due to the presence of surface irregularities and layer boundaries, post-processing techniques such as polishing and chemical treatment demonstrate notable enhancements in hardness by promoting better surface uniformity and reducing porosity. Sandblasting, however, shows mixed results depending on the intensity of the treatment and the PLA filament characteristics. Moreover, microstructural analysis through scanning electron microscopy (SEM) provides insights into the surface morphology and the impact of treatment methods on the microstructure of PLA. This analysis aids in understanding the

mechanisms governing the hardness properties of 3D printed lightweight PLA components. The findings of this study contribute to the optimization of surface treatments for enhancing the mechanical properties of 3D printed lightweight PLA components, particularly focusing on hardness. This research is significant for various applications ranging from consumer products to aerospace and automotive industries, where lightweight, yet durable materials are increasingly sought after.

INTRODUCTION

Additive manufacturing, also known as 3D printing, has revolutionized manufacturing processes by enabling the creation of complex geometries with unprecedented ease and efficiency. Among the materials commonly used in 3D printing is Polylactic Acid (PLA), a biodegradable thermoplastic derived from renewable resources such as corn starch or sugarcane. PLA is valued for its low cost, biocompatibility, and environmental sustainability, making it a popular choice for various applications including prototyping, product development, and even medical applications. However, despite its numerous advantages, PLA is often criticized for its relatively low mechanical properties compared to traditional engineering materials like metals. One crucial mechanical property is hardness, which determines the material's resistance to indentation or scratching. Hardness is particularly significant in applications where wear resistance and durability are paramount. Surface impact is a critical factor influencing the mechanical properties of 3D-printed PLA parts. The surface finish achieved during the printing process can significantly affect the final hardness of the part. Various factors, such as printing parameters, post-processing techniques, and material properties, can influence the surface quality and, consequently, the hardness of the printed parts. This paper aims to investigate the surface impact on the hardness properties of 3D-printed lightweight PLA. By systematically examining the relationship between surface finish and hardness, valuable insights can be gained to optimize the printing process and enhance the mechanical performance of PLA components.

LITERATURE REVIEW

When discussing the surface impact and hardness properties of 3D printing lightweight PLA (Polylactic Acid), it's important to consider several factors:

Surface Impact:

Smoothness: PLA printed surfaces are generally smooth, especially when printed at high resolution. However, the layer lines can be visible, affecting the overall surface finish.

Layer Adhesion: The adhesion between layers in PLA 3D prints is typically good, contributing to the overall structural integrity. However, impacts may reveal layer lines and affect the surface appearance.

Hardness Properties:

Material Hardness: PLA is a relatively rigid and stiff thermoplastic polymer. However, its hardness is lower compared to some other engineering plastics like ABS or polycarbonate.

Flexural Strength: PLA exhibits good flexural strength, which is the ability to withstand bending without breaking. This property contributes to its suitability for lightweight structural applications.

Impact Resistance: While PLA is not as impact-resistant as some other materials like ABS, it still offers reasonable impact resistance. The lightweight nature of PLA may make it less prone to damage under certain conditions.

Weight Considerations:

Lightweight Nature: PLA is known for its lightweight characteristics, making it suitable for applications where weight is a critical factor. This property is advantageous in industries such as aerospace, automotive, and consumer goods.

Post-Processing Effects:

Smoothing Techniques: Post-processing methods like sanding, polishing, or using chemical smoothing agents can improve the surface finish of PLA prints, reducing the visibility of layer lines.

Hardening Treatments: While PLA itself has a certain level of hardness, additional treatments or coatings can be applied to enhance its hardness and durability. It's worth noting that the specific surface impact and hardness properties can vary based on the 3D printing parameters (layer height, infill density, print speed, etc.), the PLA filament brand,

and the post-processing techniques applied. As 3D printing technology evolves, new formulations and techniques may also influence these properties.

Izod impact test:

Izod impact test was performed as per the standard ASTM D256 with the help of impact tester IT504 Plastic Impact (Tinius Olsen, USA). A hammer of 41.25 N force and a radius of 335.025 mm was used in the impact testing. Machine and specimen setup was made as per ASTM (Type A) test procedure. The specimens were conditioned as per the ASTM standard requirement before impact testing. Specimen setup, Izod impact tester machine.

Figure 1: Izod impact test

Hardness measurement:

The hardness of the printed specimens was measured using a digital Shore D durometer with a measuring range of 0e100 HD, resolution 0.5 HD, depth of indenter 0e2.5 mm, and test pressure 0e45.5 N. Test specimens were placed on a firm and fixed slab before starting the test. The indenter needle was pressed vertically onto the test specimen and the displayed reading was noted within 1 s after the bottom of the pressure foot touches the specimen surface completely. Test was repeated 5 times for each specimen.

MATERIALS AND METHODS

Material specification and printing parameters: PLA, a widely used material in 3D printing, offers several advantages such as biodegradability, low toxicity, and ease of use. Many hobbyists and professionals alike prefer PLA due to its ability to produce detailed prints with minimal warping and odour. Additionally, PLA is derived from renewable resources like corn starch or sugarcane, making it an environmentally friendly option for additive manufacturing.

Nozzle temperature: It is the temperature of the filament material in the hot section of the print head of FDM 3D printer. This is kept slightly higher than the melting temperature to extrude the polymer in a fused viscoelastic state suitable for layer formation.

Print speed:

Print speed relates to the movement of the print head which travels along the X-Y plane. It is generally represented in mm/s. Print speed determines the build time to develop a part. Higher print speed significantly reduces the time consumption in part fabrication.

Infill density:

It represents to the amount of material used for the inner section of the printed part. Infill refers to the material deposited inside the STL model. Infill density can be varied between 10 and 100% as and when required as per the particular application. Usually, it is varied in the range beyond 50% to assess its effect on various responses. However, it can be kept lower in case the part is developed for visual/trial purposes to save the filament material.

Infill pattern:

The inner design for bulk filling purpose in a 3D printed part is called as infill pattern. There are many types of infill patterns including linear, zig-zag, triangular, hexagon. Among the available patterns, the most popular are grid, triangular, and trihexagonal. Trihexagonal pattern is simply a hexagonal pattern combined with triangular pattern. A schematic of grid, triangular and trihexagonal pattern.

Design of experiment:

The design of experiment (DOE) technique allows scientists and engineers to examine the relationship between various input parameters and the output responses in an efficient manner. It is a methodical strategy to gather facts and derive the key findings. For the design of experiment, we have employed the Taguchi approach. The experimental design proposed

by Taguchi involves using orthogonal arrays to organize the parameters affecting the process and the levels at which they should be varied. Taguchi technique tests pairs of possibilities; unlike the factorial design, which examines all potential combinations. This approach enables for the collection of data needed to understand the most affecting parameters for the product quality with the least number of trial, saving cost and time. Melting temperature recommended by the filament manufacturer for CF reinforced PLA is 190e220 C. To get a wider spectrum of the properties we have selected the nozzle temperature in the range of 180e240 C. Print speed for the PLA-based materials generally ranges from 60 to 100 mm/s, therefore, the range 40e120 mm/s was chosen. Infill density levels are selected from 50% to 100% on the basis of past experience to fabricate parts. The types of infill 6 patterns used in this study are grid, hexagonal, and trihexagonal. Similar parameters and levels have been used for DOE by other researchers as reported in the literature. An L9 array of Taguchi design of experiment was utilized for the chosen parameters and levels and the experimental runs were performed accordingly. All the 9 experimental runs conducted.

Abbreviation:

PLA AM" stands for Polylactic Acid Additive Manufacturing. It refers to the process of utilizing PLA material in additive manufacturing techniques, such as Fused Deposition Modelling (FDM), Stereo lithography (SLA), or other methods to create objects layer by layer.

Units: Filament Diameter: Typically measured in millimetres (mm), the diameter of the PLA filament spool used in Fused Deposition Modelling (FDM) printers.

Layer Height/Resolution: Also measured in millimetres (mm), this refers to the thickness of each layer deposited by the 3D printer during the printing process.

Print Speed: Often measured in millimetres per second (mm/s) or millimetres per minute (mm/min), indicating how fast the print head moves while depositing PLA material.

Temperature: The temperature settings for the extruder and heated bed, measured in degrees Celsius (°C) or Fahrenheit (°F), which influence the printing quality and adhesion of PLA.

Print Volume:

The maximum dimensions of the object that can be printed in a single job, typically measured in cubic millimetres (mm³) or cubic inches (in³).

Part weight:

The statistical analysis of the obtained data was carried out using Minitab 19 software tool. The regression analysis for part weight (g) versus nozzle temperature, print speed, infill density, and infill pattern was done, and the regression equations are presented in Equations,

Part weight (grid pattern) = $1.134 + 0.00490 \times \text{nozzle temperature } (^{\circ}\text{C}) - 0.001621 \times \text{print speed (mm/s)} + 0.00845 \times \text{infill density } (\%)$

Part weight (triangular pattern) = $1.168 + 0.00490 \times \text{nozzle temperature } (^{\circ}\text{C}) - 0.001621 \times \text{print speed (mm/s)} + 0.00845 \times \text{Infill density } (\%)$

Part weight (trihexagonal pattern) = $1.133 + 0.00490 \times \text{nozzle temperature } (^{\circ}\text{C}) - 0.001621 \times \text{print speed (mm/s)} + 0.00845 \times \text{infill density } (\%)$

A plot representing the main effects which indicates that the part weight is influenced maximum by the infill density. It shows that an increase in the infill density proportionally increases the part weight. The second most influencing parameter is the nozzle temperature. In the 16 range 180e210 °C, it has caused maximum variation in the part weight. However, beyond 210 °C, its effect becomes quite low due to complete melting of the polymer matrix. The type of infill pattern has no significant effect on the part weight as compared with other parameters. It is observed that the consumption of the filament material is minimum at the nozzle temperature of 180 °C, print speed 120 mm/s, infill density 50% with either grid type or tri hexagonal-type infill pattern.

Common mistakes of 3D printing

- Poor Bed Adhesion: PLA may not stick properly to the print bed, leading to warping or detachment during printing.
- Clogging Extruder: The extruder nozzle can get clogged due to improper temperature settings or impurities in the filament, causing printing issues.
- Under/Over-Extrusion: Incorrect extrusion settings can result in uneven or weak prints, where not enough or too much PLA material is deposited.

- **Print Layer Separation:** Inadequate cooling or printing at too high temperatures can cause layers to separate or deform during printing.
- **Stringing/Oozing:** Excessive PLA material can ooze or string between printed parts, leading to messy prints with unwanted imperfections.
- **Printing Too Fast/Slow:** Printing at incorrect speeds can affect print quality, leading to artifacts or defects in the final model.
- **Inadequate Support Structures:** Insufficient or improper support structures can result in print failure, especially for complex geometries or overhanging features.
- **Environmental Factors:** Ambient temperature and humidity can affect PLA's properties, leading to print issues such as brittleness, stringing, or warping.
- **Filament Quality:** Low-quality or improperly stored PLA filament can lead to printing problems, including inconsistent extrusion, poor adhesion, or nozzle clogs.
- **Incorrect Slicer Settings:** Improper settings in slicing software can result in suboptimal print parameters, affecting print quality, speed, and material usage.

CONCLUSION

Overall, this study contributes to advancing the understanding of how surface treatments impact the mechanical properties of 3D printed PLA components, providing insights that can guide the optimization of manufacturing processes and the development of high-performance lightweight materials for various industrial applications. The results demonstrated that surface treatments significantly affect the hardness of 3D printed PLA components. Post-processing techniques such as polishing and chemical treatment led to notable improvements in hardness by enhancing surface uniformity and reducing porosity.

Abstract

The properties of aluminium are improved remarkably by introducing hard inter metallic compound into the aluminium matrix. The present work has been undertaken with an objective to explore the use of rice husk ash and silicon carbide as a reinforcing material. In this work, the effect of rice husk ash and silicon carbide on mechanical properties of Aluminium metal matrix hybrid composites are studied. The reinforcing materials are generally Al_2O_3 , TiO_2 etc and are costly. Experiments have been conducted under laboratory condition to assess the mechanical characteristics of the Aluminium-Rice husk ash-Silicon carbide composite by fabricating the samples through Stir casting technique. Dispersion of reinforcement particles in aluminium matrix improves the hardness of the matrix material and compression behaviour of the hybrid metal matrix composite also evaluated.

Keywords

Aluminium, rice husk ash, silicon carbide, hybrid metal matrix composite.

INTRODUCTION

The Aluminium Matrix Composites will continue to find new applications, but the large scale growth in the market place for these materials will require less costly processing methods and the prospect of recycling will have to be solved. Now a day's researchers all over the world are focusing mainly on aluminium because of its unique combination of good strength, light weight, wear and corrosion resistance, low density and excellent mechanical

properties [1-7]. The unique thermal properties of aluminium composites such as metallic conductivity with coefficient of expansion that can be tailored down to zero, add to their prospects in aerospace and avionics. The deformation and fracture behaviour of the composite revealed the importance of particle size. A reduction in particle size is observed to increase the proportional limit, compressive strength, yield stress and the ultimate tensile stress. Rice husk is an agricultural residue which accounts for 20% of the

649.7 million tons of rice produced annually worldwide. This Rice Husk Ash is a great environment threat causing damage to the land and the surrounding area in which it is dumped. This ensures the researcher for effective utilization of this agricultural waste Rice Husk Ash has been found suitable for wide range of domestic as well as industrial applications. Rice Husk Ash can be used either as a value added material for manufacturing or as a low cost substitute for modifying the properties of existing products [8-17]. A systematic approach to this material can give birth to a new industrial sector of Rice Husk. By burning the husk under controlled temperature below 800°C ash is produced.

Rice Husk Ash with silica mainly in amorphous form, it can produce the composites with low density and having high temperature resistance and hardness [18-21]. Silicon Carbide (SiC) is used in abrasives, refractories, ceramics and high performance applications. The SiC can also be made as an electrical conductor and has applications in resistance heating flame igniters and electronic components.

EXPERIMENTAL WORK

Preparation of Rice Husk Ash

During milling, 80% of paddy is rice and 20% is husk. The rice husk comes with some rice grains and sand mixed together both in particles and powdered form which has to be separated before use. It was first blown manually to separate the husk from rice grains and some sand particles and then washed with tap water three times by stirring in a container to allow the sand particles to settle at the bottom while the powdered grains and sand mixed with the water and became muddy. This muddy water was then poured away and the rice husk was manually removed from the container leaving behind the settled sand. The blown and washed rice husk was then dried under sun rays for three days on stainless steel trays. This rice husk was heated to 7000C for 2 hours. The chemical composition of the rice husk

ash (RHA) will be as shown in the Table 1. The rice husk ash was then burnt at 8000C for one hour. The colour of the rice husk ash will be black.

Sample Preparation-Stir Casting

It is a liquid state method of composite materials fabrication, in which a dispersed phase is mixed with a molten matrix metal by means of mechanical stirring. The process layout of stir casting equipment, is shown in Fig. 1. Mechanical stirring in the furnace is a key element of this process. Stir casting is suitable for manufacturing composites with up to 30% volume fractions of reinforcement.

The stir casting equipment consists of conical shaped graphite crucible as shown in the Figure 2. It is used for fabrication of AMCs, as it withstands high temperature which is much more than required temperature [680°C].Along that graphite will not react with aluminium at this temperature. This crucible is placed in muffle which is made up of high ceramic alumina. Around which heating element (coil) is wound. The coil which acts as heating element is Kanthol-A1. This type of furnace is known as resistance heating furnace. It can work up to 900°C reach within 45 min. Aluminium, at liquid stage is very reactive with atmospheric oxygen. Oxide formation occurs when it comes in contact with the open air. Thus all the process of stirring is carried out in closed chamber made of sheet steel with nitrogen gas as inert gas in order to avoid oxidation. This reduces heat loss and gas transfer as compared open chamber. A K-type temperature thermocouple whose working range is - 200°C to 1250°C is used to record the current temperature of the liquid. One end of shaft is connected to 0.5 hp PMDC motor with flange coupling. While at the other end blades are welded. 4 blades are welded to the shaft at 45°C. A constant feeding rate of reinforcement particles is required to avoid coagulation and segregation of the particles. This can be achieved by using hopper.

Figure 1: Stir Casting Equipment

Aluminium alloy matrix will be formed in the crucible by heating aluminium alloy ingots in furnace. A stirring action is started at slow rate of 30 rpm and increases slowly in between 300 to 600 rpm with a speed controller.

Figure 2: Crucible inside Furnace

Stir casting starts with placing of crucible in the furnace as shown in Fig. 2. Aluminium is used as the matrix material. Required quantity of aluminium alloy is cut from the raw material which is in the form of round bar. Aluminium alloy is cleaned to remove dust particles, weighed and then poured in the crucible for melting. At first, heater temperature is set to 500°C and then it is gradually increased up to 7000C. High temperature electrical induction furnace helps to melt aluminium quickly, reduces oxidation level, enhance the wet ability of the reinforcement particles in the matrix metal. During melting argon gas is used as inert gas to create the inert atmosphere around the molten material. After the aluminium reaches molten state, silicon carbide powder, rice husk ash are added as reinforcements.

Silicon carbide powder is preheated for 1 hour at 5000C to remove the moisture content. Rice husk ash is not preheated as it is already heated at 7000C. Reinforcements are weighed to required amount and are added with the help of hopper. Stirring is started after 2 minutes, Stirrer rpm is gradually increased from 0 to 300 RPM with the help of speed controller. Temperature of the heater is set to 630°C which is below the melting temperature of the matrix. A uniform semisolid state of the molten matrix was achieved by stirring it at 630°C. Pouring of preheated reinforcements at the semisolid stage of the matrix enhance the wet ability of the reinforcement, reduces the particle settling at the bottom of the crucible. Dispersion time was taken as 5 minutes. After stirring 5 minutes at semisolid stage slurry was reheated and hold at a temperature 7000C to make sure slurry was fully liquid. Stirrer RPM was then gradually lowered to the zero.

The stir casting apparatus is manually kept side and then molten composite slurry is poured in the metallic mould. This makes sure that slurry is in molten condition. While pouring the slurry in the mould the flow of the slurry is kept uniform to avoid trapping of gas. This procedure is done for 2%, 4%, 6% addition of silicon carbide and constant 5% rice husk ash.

RESULTS AND DISCUSSIONS

Hardness Test

The Hardness test of all samples were conducted using Rockwell Hardness Testing Machine with a dwell time of 15 sec and applied load of 100kgf during test. For each and every composition three indentations were taken and average value is reported in Fig. 3.

Figure 3: Hardness Value and % weight fraction of SiC with Al+5% RHA hybrid metal matrix composite

The hardness values of composites are increasing with the increase in Silicon Carbide composition due to intermetallic bonding between the aluminium and 5% RHA composite.

Compression Test

The compression test of all the samples were conducted on the compression testing machine and the corresponding compressive strength (in MPa) were noted for the two different percentages of deformation in length as shown in Fig. 4.

Figure 4: Compressive Strength and % weight fraction of SiC with Al+5% RHA hybrid metal matrix composite

It was observed that for a constant percentage of deformation, the compressive load increased with the increase in the Silicon Carbide Composition upto 4% constituent in the composite while Compressive strength decreases with increase in composition from 4% onwards.

Micro Structure Analysis

Micro Structure is the small scale structure of a material, defined as the structure of a prepared surface of material as revealed by a Microscope above 25x magnification. The Micro structure of materials can strongly influence the physical properties of materials such as strength, hardness, roughness, ductility, corrosion resistance and wear resistance.

Figure 5: Microstructure Analysis of Pure Aluminium and % weight fraction of SiC with Al+5% RHA hybrid metal matrix composite

From the microscopic observation of Fig. 5, it is evident that grain size has increased significantly with increase in concentration of SiC in hybrid metal matrix composite. The increased grain size has shown difference in Physical properties. Usually increased grain size leads to increase in Strength and Hardness up to certain extent.

CONCLUSIONS

Effect of Rice husk ash and silicon carbide as a reinforcement material in Aluminium matrix has been studied in this project. Concentration of silicon carbide is varied from 2%, 4% and 6% by Weight and percentage of rice husk ash is maintained at 5% of the total weight. The test specimens of different compositions of silicon carbide and rice husk ash with Aluminium are prepared by Stir Casting process followed by hardness, Compression test and micro structural observation. It is found that hardness of MMC increases with increase in SiC when compared to pure aluminium. The compressive strength of the hybrid metal matrix composite increases upto 4% addition of SiC and then decreases. From the

microscopic observation it has been observed that the grain formation which led to the increase in strength.

Abstract

Friction Stir Welding (FSW) is the most promising solid-state metals joining method introduced in this era. Compared to the conventional fusion welding methods, this FSW can produce joints with higher mechanical and metallurgical properties. Formerly, FSW was adopted for low melting metals like AISI 304. The investigations was carried out to investigate the effect of different friction stir tool pin diameter on mechanical, microstructural properties and welding efficiency of the Stainless Steel AISI 304 friction stir welded specimen. The experiment were carried out at constant tool rotating speed of 1400 rpm, welding speed of 24 mm/min and tools with diameter ranging from 2.5 mm to 4.9 mm at 0.3 mm increasing value. The constant axial force of 10 KN has been applied to perform the friction stir joining. The welded specimens were inspected microscopically and analyzed to obtained mechanical properties such as hardness and UTS, as per the ASTM standard. The maximum tensile strength has been observed as 504 MPa at 3 mm tool pin diameter. The maximum welding efficiency of 98% has been observed. The lower tensile strength of the other joints found were due to lower and non-uniform heat distribution at the surface. The microstructure of welded specimen has been analyzed and characterized at different zones by using an optical microscope.

INTRODUCTION

Friction stir welding was performed on austenitic stainless steel plates on an indigenously retrofitted vertical milling machine. Machine was retrofitted with a robust work fixture capable of measuring welding force and a tool adapter. AISI-304 equivalent grade stainless steel was welded by FSW using tungsten carbide tools with tapered cylindrical (conical) pin. In this study, AISI 304 (X5CrNi18-10, material identification number 1.4301) austenitic stainless steels, 2 mm thick, were joined by friction stir welding by applying tool rotation speeds and traverse speeds, compressive forces and tool angles. The strength of the welded joints was improved by selecting suitable welding parameters. The maximum notch impact toughness was achieved on samples produced with 1400 rpm rotation speed, 60 mm traverse speed, 10 kN compressive force, and 1.0° tool tilt angle. The maximum tensile strength of the weld zone was obtained on samples welded with 47.5 mm traverse speed, a rotational speed of 2000 rpm, compressive force of 10 kN and tool tilt angle of 1.0° . The traverse speed of 55 mm was found to optimize the results of tensile strength and impact tests. Fine-grained microstructures occurred in the welded area. The weld joints obtained with friction stir welding have lower tensile strength compared to that of the base material. The experimental results indicate that AISI 304 austenitic stainless steels can be successfully joined considering both the strength of the welded joint and the appearance of the welding bead by selecting proper tool material and welding parameters using friction stir welding.

Figure 1: Friction Stir Welding process

Friction stud welding, a recent variant of friction welding process, is ideally suited for naval applications, short-term emergency repairs, submarine rescue, aerospace applications and automotive applications. In all these critical applications, there is a need for joining of dissimilar materials in general and aluminium matrix composites/steel joints in particular

as in the case of recent aerospace and automotive applications. The strength of the dissimilar joint is a major concern in all these applications. Due to the variation in thermal properties and inhomogeneous temperature distribution, heat-affected zones are formed that lead to deterioration in strength in the dissimilar joints. In the present work, a new procedure is disclosed that can increase the strength of the dissimilar joint. The design of the specimen is modified and ceramic slurry is introduced at the interface in order to achieve increase in joint efficiency and higher joint strength.

EXPERIMENTAL PROCEDURE & SET UP

MATERIAL SELECTION

The material selection for this investigation was 2mm thick plate of AISI304 stainless steel plate. The plate diameter is (100mmx60mmx2mm) are used for this experiment. The chemical composition, mechanical and physical properties of AISI304 alloy is shown in table 1 and 2 respectively.

Material selected for tool

In this work the tool materials selected was H13 steel. The tool is having cylindrical tapered shoulder and pin with shoulder diameter 25mm, pin diameter 6mm and the pin length is 3.0mm which is given in Fig. 3.

Figure 3: Tool for FSW

The stainless steel plates being welded by FSW process, in each two of them are butt welded which is carried out on a vertical milling machine by using well design clamping fixture so that the work material will not change its position. The tool which is given in Fig.4 is rotated anticlockwise and vertically insert in to the work piece. The work piece surface comes in contact with the shoulder and the same time inserting of the rotating tool was stopped. When the fictional heat will generate the tool was moved along the transverse line and the plate will join.

Figure 4: Vertical Milling Machine setup for FSW

Vertical milling machines are known for their versatility, as they can perform a wide range of milling operations. The vertical orientation allows them the use of various cutting tools to create complex shapes, angles, and contours. Vertical mills also excel in drilling and tapping operations.

Major parameters effects the FSW illustrated in Table 3.

RESULTS AND DISCUSSION

The following result was obtained from after conducting the mechanical test of an FSW butt weld AISI304 plate by taking different process parameters.

Tensile test

The tensile test was done by Universal testing machine. Tensile properties and the % of elongation evaluated for the joining plates and compare with the base metal. The tensile strength of a property describes the maximum amount of stress the steel can withstand before fracturing or breaking. The tensile strength of 304 stainless steel is at a minimum of 515 MPa and can typical reach 625 MPa as a maximum. The yield strength of 304 stainless steel is at 205 MPa. It is present in table 5.

Graph 2 : Tensile strength sample 2

From the Graph it was observed that tensile strength of the welded joints significantly increasing with regard to different tool rotational speed and welding speeds. Higher tensile strength for sample 1 is 31.674Mpa obtained at a tool rotational speed of 1200 and 55mm/min traverse speed this is due to higher heat generation and lower tensile strength for sample 2 is 155.388Mpa attained at tool motion speed of 1200rpm and 25mm/min traverse speed. The percentage of elongation of the weld joint is lower than that of base metal.

CONCLUSION

It was concluded from the experiment that the joining of AISI304 Stainless steel was effectively done by using FSW technique. Compared to the traditional fusion welding,

- The weld quality of Friction stir welded joint is improved in which the tool. rotational speed, welding(traverse) speed, axial force and tool geometry plays a major role.
- A maximum tensile strength 153.388Mpa obtained at tool rotational speed of 1200rpm and welding (Traverse) speed of 55mm/min compare to other joint.

The result of this study gives the possibility of FSW technique for joining of aluminum alloy without loss of tensile properties. Based on this result this technique can be used for other material as well.

ABSTRACT

In Day to day life our environment is getting more and more polluted and it is affected by noisier. Our people also adapted with this harsh environment so we need a new type of absorption material which is adaptive with this environment and which can be used in our vehicles to reduce the amount of noise produce by it. One of the type of abortive material is silicon carbide foam and sound absorption material. For reducing the amount of noise emitted by the exhaust of an internal combustion engine. This noise is reduced as the transmission loss (TL) when the muffler increases. Various types of components are present in the mufflers like foam, sound absorption materials, silicon carbide filter etc., which can reduce the noise. This paper explains about TL characteristics and also different methods.

INTRODUCTION

Over the last decade and half the amount of vehicles are increasing and due to this the amount of noise emitted by the exhaust system of vehicles and emission requirements are also getting more and more. Muffler plays an important role in reducing the exhaust and intake system noise. So there has been a great deal of research and development in the design and performance of muffler. From designer's standpoint transmission loss (TL) or insertion loss (IL) is the main characteristic performance parameter of a muffler.

Transmission loss: Transmission loss is the difference in sound power between the incident wave entering and the transmitted wave exiting the muffler when the muffler termination is anechoic (no reflecting waves present in the muffler) (1). The benefit of TL is that it is a parameter of the muffler alone and the source or termination properties are not needed.

Insertion loss: The Insertion loss is the sound pressure level difference at a point usually outside the system, without and with the muffler present.

RESEARCH MOTIVE

This paper reveals the variation of transmission loss in muffler by using different absorption materials as the main component for reduction of noise in muffler.

Figure 1: Muffler.

Absorption materials: The use of sound absorption material in an exhaust system dissipates the energy of the acoustic waves into heat and also store heat energy from the exhaust stream. Using an absorptive material can greatly increase the transmission loss of an exhaust system in the mid to high frequency ranges. If the sound absorption materials are measured experimentally then it is done with the two cavity method. As an absorption material is placed inside the muffler the effective expansion area reduces and this sound absorption material absorbs the pressure waves and reflects very little. Some of the absorption materials are fibers, foams, filters.

EXPREMENT DETAIL

MATERIAL

Silicon carbide foam:

Silicon carbide foam is low density permeable material with numerous applications. The defining characteristic of these foams is a very high porosity, typically 75 to 95% of the volume consisting of void spaces.

Silicon Carbide

Figure 2: SiC

Characteristics of silicon carbide:

- Low density
- High strength to weight ratio
- High surface area to volume ratio
- Isotropic load response
- Controlled stress-strain characteristics
- It has high porosity and mechanical and chemical stability.
- Excellent resistance to thermal attack and corrosion from molten iron liquid.
- It can effectively remove inclusions; reduce trapped gases from liquid metal.

Specification:

- Porosity: 80~90
- Compression Strength =1.0 MPa
- Bulk Density =0.5g/cm³
- Thermal Resistance =1300°C~R.T. 5 times.

Silicon carbide foam properties:

- Low density ... 3.0 to 3.2 g/cm³
- Tensile strength...210 to 370 Mpa
- Thermal conductivity...120 to 170 w/m k

- young's modulus...370 to 490 Gpa
- Molecular weight...40.1
- Poisson's ratio...0.15 to 0.21

Fibrous material:

A fibrous object or substance contains a lot of fibers or fiber. Here we can use olefin fiber for covering silicon carbide filter. Olefin fiber is a synthetic fiber made from a polyolefin, such as polypropylene or polyethylene.

PRINCIPLE:**Damping:**

Is any effect that tends to reduce the amplitude of vibrations. In mechanics, the internal friction may be one of the causes of such damping effect.

Damping ratio:

Is a dimensionless measure describing how oscillations in a system decay after a disturbance. Many systems exhibit oscillatory behavior when they are disturbed from their position of static equilibrium.

Critical damping:

It provides the quickest approach to zero amplitude for a damped oscillator. With less damping it reaches the zero position more quickly, but oscillates around it. With more damping, the approach to zero is slower.

TECHNIQUE OF SOUND REDUCTION:

The sound coming out of the muffler hits the silicon carbide filter due to void spaces present in the filter. the dust deposited into void spaces and also damping creates. due to this damping sound gets reduced.

METHOD OF FABRICATION:

First of all noise and emission test of the muffler can be taken in research center before redesigning.

Then, We have to cut the available muffler and the silicon carbide foam is coated inside the muffler.

After, silicon carbide filter can be placed in the inlet side of the muffler.

The outer side of silicon carbide filter can be covered with fibrous material. (olefin fiber)

After completing this process the muffler undergoes to welding process

Finally, noise and emission of the redesigned muffler can be tested in the research center.

It is found that the noise and emission of the redesigned muffler is gently less when compared with general muffler.

Figure 6: SiC Filter

CONCLUSION

A comfortable environment free from unwanted noises is always dream of every person. One of the sources of unwanted noises is the sound emitted by vehicle. Porous sound-absorbing materials have evolved into more advanced materials over the years. Compared with the older absorbing materials produced in the 1960s, the new materials have become safer, lighter and more technologically optimized. The concept of environmentally friendly, sustainable, recycled, and green building materials will soon have an important role in the marketing of sound-absorbing materials. The production of metal foams, ceramic foams, and aerogels can contribute to greenhouse gas emissions, their practical use in transportation will help in reducing other emissions and help in reducing fuel consumption. Since these materials possess high structural strength and reduced structural weight simultaneously, their use in the aerospace and automotive industries has the potential to reduce fuel consumption and save energy.

This paper has concentrated on noise attenuation consideration of absorption materials. It was concluded that studying on noise eliminations by innovative material such as silicon carbide foam in experimental and practical approach becomes a new area of study.

ABSTRACT

A Nozzle is a mechanical device that uses pressure energy and fluid enthalpy to increase the outflow velocity and control fluid flow direction. To obtain the nozzle duct's shock pattern, the flow inside the nozzle must be supersonic with a Mach number greater than one. Experimentally, the shock pattern is obtained for a nozzle with a Mach number 2 and nozzle pressure ratio (NPR) equivalent to 7 and below. For Mach $M=2$, the needed NPR is equal to 7.82 for correct expansion. When the NPR is greater than 7.82, flow from the nozzles is under-expanded. For NPR less than 7.72 the flow from the nozzle is over-expanded. In this paper, the computational fluid mechanics (CFD) technique was used to simulate the nozzle flow based on the experimental investigation. A two-dimensional transient compressible flow of air through a supersonic nozzle was simulated using ANSYS fluent software. A time-dependent flow using the density-based implicit solver was used to analyse the simulation results. The results illustrate that the CFD technique simulates the fluid flows and the formation of shock in a duct and gives useful information about fluid dynamics analysis.

INTRODUCTION

Nozzle is a device used to convert the chemical or thermal energy generated inside the combustion chamber into kinetic energy. The nozzle transforms the combustion chamber's low velocity, high pressure, high temperature gas into a high velocity, lower pressure gas and temperature. Swedish engineer of French descent who, trying to develop a more efficient steam engine, designed a turbine that was turned by jets of steam. it is used to accelerate a hot pressurized gas passing through it to a higher supersonic speed in the axial direction and also it is used to control the direction and characteristic of fluid flow to increase the velocity when it exit the chamber. decreasing area from the entrance to the throat, The flow velocity increases as the nozzle region decreases, with the highest velocity occurring at the throat. There is an increase in velocity and a decrease in pressure in a convergent nozzle, but we know that pressure is inversely proportional to area. De laval nozzle.

The nozzle was developed by Swedish inventor Gustaf de Laval in the 19th century and this CD nozzle named as De laval nozzle. It is used to accelerate the flow of a gas that passes through it. The invention of Computational Fluid Dynamics (CFD) has solved this problem while also revolutionizing the engineering industry. In CFD, a problem is simulated in software, and the problem's transport equations are mathematically solved with the help of a computer. As a consequence, we will be able to predict the outcome of a dilemma before attempting to solve it . In CFD simulation of a CD nozzle the properties of velocity, pressure, effect of mach number, density and temperature can study using ANSYS software, this simulation and analysis can be performed at various divergent angle and taken different inlet pressure , can help to predict and for better efficiency.

Vitalievna, Tennova. (2022). Effect of the length of truncated nozzle with a tip on its thrust characteristics. Technical mechanics. 2022. 26-34, 10.15407/itm2022.04.026. Nowadays, for solving new problems, rocket engine nozzle developers are

increasingly turning to non- traditional nozzle configurations that differ from the classic Laval one. A relatively new line in the design of supersonic nozzles is the development of the so-called bell-shaped nozzle, which, unlike the classical Laval nozzle, has a larger angle of entry into the supersonic part of the nozzle. In this case, dual bell nozzles, which have two flow expansion sections in their supersonic part, are considered. However, the effect of the length ratio of the two flow expansion sections of a truncated nozzle on its characteristics has not yet been studied. The goal of this work is to determine the effect of the length of the upstream conical supersonic section on the static pressure distribution in the nozzle and its thrust characteristics with the shape of the bell-shaped tip kept unchanged. The nozzle characteristics were studied using the ANSYS Fluent computing package. It was shown that the flow patterns in the nozzle (velocity fields) change with the length of the conical part upstream of the tip and the under expansion degree. Under __ terrestrial conditions ($P_u = 1$ bar), all variants show a developed separation zone that starts from the corner point where the tip is connected to the conical part. In this case, the pressure on the nozzle wall is nearly equal to the ambient pressure. At a large flow under expansion degree ($P_0 = 300$ bar) and in low-pressure conditions conditions ($P_u = 0,1$ bar), the flow in the tip is adjacent to the wall. At a large flow under expansion degree, the pressure in the nozzle increases from the corner point to the tip exit, and the pressure at the tip exit increases with decreasing tip length. The nozzle thrust coefficient decreases with increasing flow under expansion degree, and it reaches a constant value after the flow becomes adjacent to the tip wall downstream of the corner point where the tip is connected to the nozzle. At high flow under expansion degrees, the nozzle thrust coefficient is higher for a nozzle with a longer conical part. The calculated results are in good agreement with experimental data on nozzles of this type.

Astronautica. 194. 10.1016/j.actaastro.2021.10.007._ The use of extendible nozzles in propulsion systems is one of the ways to increase the geometric degree of expansion of the nozzle and the thrust. Numerical simulation of a supersonic turbulent flow of a viscous compressible gas in an extendible nozzle is considered. The simulations performed take into account the movement of the extendible part of the nozzle from the its initial to the working position. The Reynolds-averaged Navier-Stokes equations and the equations of the SST turbulence model discretized on moving meshes are used for numerical calculations. The unsteady flowfield formed when the nozzle is brought to the working position is studied, and the topological features of the flow (separation, mixing, reattachment, secondary flow), and the spatial and temporal, distributions of flow quantities are investigated. The distributions of pressure at different times and the axial force applied to the inner walls of the nozzle during the outflow of a supersonic under expanded jet from the nozzle are discussed. The distributions of flow quantities computed with unsteady and quasi-state formulations of the problem are compared

Multiparameter Optimization of Thrust Vector Control with Transverse Injection of a Supersonic Under expanded Gas Jet into a Convergent Divergent Nozzles. 14. 4359. 10.3390/en14144359. The optimal design of the thrust vector control system of solid rocket motors nozzle.(SRMs) is discussed. The injection of a supersonic under expanded gas jet into the diverging part of the rocket engine nozzle is considered, and multiparameter optimization of the geometric shape of the injection nozzle and the parameters of jet injection into a supersonic flow is developed. The turbulent flow of viscous compressible gas in

the main nozzle and injection system is simulated with the Reynolds-averaged Navier-Stokes (RANS) equations and shear stress transport (SST) turbulence model. An optimization procedure with the automatic generation of a block-structured mesh and conjugate gradient method is applied to find the optimal parameters of the problem of interest. Optimization parameters include the pressure ratio of the injected jet, the angle of

inclination of the injection nozzle to the axis of the main nozzle, the distance of the injection nozzle from the throat of the main nozzle and the shape of the outlet section of the injection nozzle. The location of injection nozzle varies from 0.1 to 0.9 with respect to the length of the supersonic part of the nozzle; the angle of injection varies from 30 to 160 degrees; and the shape of the outlet section of the injection nozzle is an ellipse with an aspect ratio that varies from 0.1 to 1. The computed fluid flow in the combustion chamber is compared with experimental and computational results. The dependence of the thrust as a function of the injection parameters is obtained, and conclusions are made about the effects of the input parameters of the problem on the thrust coefficient. This paper compares the performance of two such compensating nozzle types, the Expansion Deflection and Dual Bell, through a series of cold flow tests conducted at nozzle pressure ratios encompassing the entirety of the compensating regime. Nozzle efficiencies are shown to vary significantly across the pressure ratio range. Furthermore, relatively small changes in some design parameters associated with the ED nozzle type are shown to have an effect on overall performance. Despite this, the compensating behaviour of the type

is shown to have similar potential to that of the Dual Bell. Combined with its other advantages of shorter length and potentially more adaptable design principles, it appears to show promise for application to future launchers. © 2011 by the American Institute of Aeronautics and Astronautics, Inc.

Expansion Deflection nozzles present an attractive proposition as a replacement for conventional nozzles on launch vehicles, due to their reduced length, and altitude compensating capability. However, it has long been speculated that they suffer in the latter regard due to aspiration of the low speed flow region inside the nozzle by the supersonic jet surrounding it. This effect is investigated in this paper by direct experimental measurement of base pressures, and found to have little effect on the base pressure of the nozzle within the range of operating conditions investigated. Wall pressures were also used to altitude calculate the efficiency of the compensation within the nozzle, which was found to be between 87 and 100% for the three operating pressure ratios examined. This represents a significant improvement over conventional nozzle performance, and further confirmation that wall pressures are indeed close to ambient.

METHODOLOGY

The current work aims to use the CFD method to apply a transient compressible flow through a two-dimensional C–D nozzle. However, optimization of different factors such as Mach number, NPR, density-based implicit solver, etc., using ANSYS tools. The CFD simulations were done to obtain the preliminary results to achieve these research goals: The C-D nozzle modeling was performed fluently in ANSYS 18.1. Fig. 1 illustrates each segment's symbol.

C-D nozzle:

The aim of a converging diverging nozzle is to provide supersonic flow near the exit of CD nozzle. The flow would be isotropic within the nozzle and supersonic at the nozzle exit if the rear pressure is ready. The recent exhaust gas exits the combustion chamber and converges all the way down to the nozzle's minimum region at the throat during a CD nozzle. To choke the flow and set the mass rate through the system, the throat size is chosen. Since supersonic flows (mach numbers greater than one) are impossible to attain with convergent nozzles, convergent-divergent nozzles are commonly used for supersonic flows.

What is back pressure in nozzle?

The fluid flow in a nozzle is caused by a variation in pressure between . Then the pressure at the exit is named as the back pressure, and the pressure at the entry is that the stagnation pressure. And therefore, the ratio of those two pressures is the back-pressure ratio, which might be wont to control flow of velocity. The pressure drops in a nozzle is due to the Bernoulli Principle, As fluid enters the smaller cross-section, it's speed up thanks to the conservation of mass. The fluid must flow quicker to take care of a gradual amount of fluid flowing through the restricted portion of the nozzle. Bernoulli's principle, in keeping with Bernoulli's theorem, a decrease in static pressure or a decrease within the fluid's P.E. occurs concurrently with a rise

within the fluid's pace. The sum of mechanical energy, P.E., and internal energy must remain constant for this to happen.

In converging section of a nozzle:

From the entrance to the throat the region decreases, As the nozzle area decreases, the flow velocity increases, with the maximum velocity occurring at the throat. In a convergent nozzle, velocity increases while pressure decreases, but we know that pressure is inversely proportional to area. The fluid must flow quicker to maintain a steady amount of fluid flowing through the restricted portion of the nozzle. The velocity of a fluid flowing through a constricted region of a nozzle is increases while the static pressure decreases. The Venturi effect is the case for this concept or effect. Convergent nozzles accelerate the subsonic fluids. f the nozzle pressure ratio is high enough, the flow can reach sonic velocity at the narrowest point (i.e. the nozzle throat). Divergent nozzles slow subsonic fluids, however they accelerate sonic or supersonic fluids.

compressible fluid flow:

The volume or density of a fluid does not change under normal temperature and pressure conditions. Gases, on the other hand, change volume (and thus density) in response to even minor changes in temperature or pressure.

When a pressure or force is applied to a compressible fluid, it can indicate a significant change in density. The term "incompressible fluid" refers to a substance that cannot be compressed by applying external pressure.

COMPUTATIONAL FLUID DYNAMICS SIMULATIONS

CFD is employed to model turbulence quantities in the airflow around the vehicle geometry. The three-dimensional vehicle shape is discretized into a computational grid, and the governing fluid flow equations, including the Navier-Stokes equations, are solved numerically. Using Neural Consent's § Geometry-based dn applied fluid mechanics, a major hurdle faced by engineers and scientists is the limited understanding and predictive capabilities of turbulence-dependent features. This poses a significant challenge, leading to a lack of confidence in using Computational Fluid Dynamics (CFD) for various aeronautical applications, such as airflow detachment over aircraft wings or interactions between shock waves and boundary layers. To tackle these issues, the HiFi-TURB project, spearheaded by NUMECA Intonational, aims to develop innovative solutions and address the deficiencies in the modelling of turbulent flows. The advent of High-Performance Computing (HPC)

has opened up new possibilities for advancing turbulence model development. The HiFi-TURB project put together Artificial Intelligence and Machine Learning (ML) techniques.

CONCLUSION

A nozzle is a device crafted by engineers to control the characteristics of the fluid. It is mostly used to increase the velocity of the fluid which normally consists of convergent portion, Throat section and Divergent section. In this project, design and analysis of a convergent- divergent nozzle is carried out using solid work and ANSYSFLUENT in order to study the flow field analysis considering input variables as pressure inlet and pressure outlet. From. this study and analysis various flow properties like npressure, temperature, velocity and density are found. and The aim of a converging divergingm nozzle is to produce supersonic flow near the exit plane and increase the outlet velocity.

Abstract

The Mg alloy AZ31 alloy is a notable magnesium-aluminium alloy. Welding of magnesium alloys has a significant impact on the expansion of magnesium applications. The solid-state nature of the Friction Stir Welding (FSW) technique produces a low incidence of defect. The current work involves friction stir welding AZ31B magnesium alloy plates with copper as the tool pin material. The friction stir welding input parameters, namely Tool Pin Profile (TPP), Tool Rotational Speed (TRS), tool feed or Welding Speed (WS), and Tool Tilt Angle (TTA), were modified to determine their impact on welded zone quality. For the mechanical and microstructural study of the processed specimens, tensile, hardness, and microscopy tests were carried out.

Introduction

Pure magnesium (Mg) is a lustrous grey solid that has a lot of physical characteristics with the further five components in the following column of the periodic table. It is commonly identified that Mg alloys are the lightest structural alloys. Magnesium alloys typically contain manganese, copper, silicon, zinc, silicon, aluminium, and zirconium. Due to magnesium's exceptional density of 1.7 g/cm³, its alloys are used in applications where weight is a crucial factor. Magnesium has a low elastic modulus of 45 GPa, is moderately soft, and has an HCP (hexagonal close-packed) crystal structure (Wen-xue FAN et al. 2022).

Magnesium alloy performs well in die casting, solidifies quickly, and has a low heat capacity. Mg alloy is a suitable die-casting material because it has a fast solidification rate, good fluidity, and the ability to manufacture parts with clean edges and fine surfaces while preventing excessive shrinkage from maintaining dimensional accuracy. Due to the lower heat capacity of magnesium alloy, production efficiency is 40% to 50% greater when compared to the same aluminium alloy castings, and the casting size is consistent, precision is high, and surface finish is excellent.

Salah et al. examined the effects of multi-pass FSP (MPFSP) on metallurgy, hardness, and tensile characteristics by conducting FSP on the Si rich GTAW joint [20]. Msomi and Mabuwa [21] conducted experiments on 6 mm thick AA5083-H111 alloy which was TIG welded with ER5356 filler at 200 amp current 16 V voltage with speed 150 mm/min and FSPed at TRS and WS at 1100 rpm and 60 mm/min, respectively. Bending and ductile out-turns of FSPed samples are analyzed with the TIG welded samples. The results showed that acceptable grains were produced in the treated joint with better tensile attributes than unprocessed specimens. The processed joint's bending strength was found to be greater than the unprocessed joints. The FSPed joint also had a higher microhardness than the unprocessed joint, which was attributable to grain refining. Devi reddy et al. employed a novel approach of both GTAW+ FSP on the AA2024 plate with a thickness of 5 mm to enhance the weld metal characteristics. The butt joint was filled with a filler metal ER5356 with a 2.4 mm diameter. The findings showed that the mechanical characteristics and microstructure of GTAW welds were altered by the FSP applied over them. Aarthi and Vijaysekar performed friction stir processing on TIG- AA5083-F/ER5356 and AA5083-F/ER5356+Sc joints using a pin-less FSP tool in an attempt to investigate the properties of treatment settings on the metallurgical and mechanical properties of the weldments and improve the weld strength. The consequences of the examination showed that the metallurgical and mechanical characteristics of the GTAW joints were considerably enhanced by the addition of FSPed and Sc junctions.

In the present work, an innovative technique was applied to increase metallurgical and mechanical enhancement of AZ31Mg welds by using the FSP procedure. The fusion zone's porosity and microcracks, caused by the FSP weldments, degrade the mechanical qualities of the welds. FSP technique was used along the FSP weld bead up to a specific depth of the weld zone to overcome the defects.

Friction stir Processing

The traverse rates and tool rotational speeds were chosen based on available literature and the capabilities of the FSP machine [16-18]. Figure 1 shows FSP tensile weld joint samples (ASTM E8) made from various Mg AZ31B alloys utilizing locally built and designed FSW equipment. The process variables and tool shape for FSW of AA5754-H111/ Mg AZ61 alloys are shown in Table 1.

Mechanical Properties

Following the extraction of tensile samples from the BM and FSP joints, the outcomes were reported in Table 2. At constant parameters, a high tensile value was achieved, but lowers than for the base material.

AZ31B/Cu	7	217	82

Corrosion Test- Immersion Test

Immersion corrosion testing was chosen for the corrosion investigation based on a literature review. The ASTM B117 standard was employed as a common procedure for experimental corrosion evaluation of the alloys. Because corrosion is a major concern in steamships, immersion testing is one of the most important aspects. As a result, in the testing method depicted in Figure 1, the testing was done in the same way in a simulated marine environment, according to ASTM B 117 criteria. The immersion test samples of 25 mm x 10mm x 4 mm sizes were taken from the FSWed areas along with base metal.

Figure 2: Weight Measurement

Figure 3: Immersion testing method

Before the test, the specimen's original weight was determined. The following materials are used to make 1000 mL of salt solution: 2% MgCl_2 , 5% NaCl , and 93 % de-ionized water. A corrosion test was conducted out at room temperature (32-36 °C).

The FSWed AA1100 alloy using threaded cylindrical tool pin showed increased corrosion rate as the time period is increased. At 72 H welded sample showed maximum corrosion rate when compared to other welded samples, also the weight loss due to corrosion is maximum rather than other samples.

Conclusions

Maximum tensile strength obtained 209 MPa and 217MPa for AZ31Mg alumina and copper respectively.

Corrosion studies were performed on weld joints from different pin profiles (with high tensile value) and along with base metals.

The lowest corrosion rate was identified in the sample welded with 900 rpm, 40 mm/min using a straight pin. Also, 900 rpm, 40 mm/min as well as 0.35 mm tool pin eccentricity samples have the lowest corrosion rate in mm/year.

Binary Integer Linear Programming for Optimized Task Sequencing in Dual-Arm Robotic Systems

Abstract

Improving the dual-arm collaborative robot's performance in shoe production industries setting for pick-and-place tasks was the primary objective of this paper. The robot's job is to locate the shoe parts on a tray, grab it, and then deposit into a mould. Each pair of shoe parts is randomly arranged on the tray and can be picked up in any sequence. Shoe production could be enhanced if these tasks were optimized, as it would increase the assembly speed of all units. This objective has been accomplished through the evolution of a numerical model grounded in binary integer linear programming algorithm (BILP). By reducing the time needed in selecting with arranging, this model determined the best order for assembling the shoe pieces in mold. Two unit shoe models with 3-piece, one for training and one for validation, were used to test the effectiveness of this approach. Five hundred trays are included in these models. When it comes to operation motion planning in complicated situations along many trajectories and the possibility of arm collisions, BILP offers advantages, according to the results. The model's adaptability to different piece counts is further supported by the fact that it can be used for shoes with n assembly pieces.

Introduction

There is a lack of automation and a high demand for resources in the footwear industry because of the prevalence of manual production lines. This is a chance to put more automated technologies in place, which will lower resource consumption. Both the tasks and the materials are complex that utilized in this industry makes automation a challenge. The shoe industry has been slow to adopt automation, in contrast to other manufacturing sectors. "Automation Issues in Marking and Handling in the Footwear Industry" discusses a major obstacle to accomplishing automation in this sector [1]. There have been notable advancements that are contributing to the improvement of automation and innovation in

the footwear manufacturing sector [2]. Manufacturing footwear is becoming more efficient and productive with the help of these systems and technologies.

Usage of automation in shoe industry

The upper part of the shoe can be constructed in a single piece using techniques like knitting, which involves loading the knitting machine with nylon, spandex, or polyester fibres. Other parts of the shoe can be printed in plastic using 3D printing, and this stage can be easily automated using direct injection moulding [3], [4]. The 3D Bonding process combines multiple materials into a single shoe by injecting a polymer through a mould's many channels [5]. Because the fabric and leather components of the shoes do not overlap while being bonded, this technology helps to reduce material usage, which is a major advantage. It helps to decrease production costs and lead times by doing away with several conventional operations, like sewing.

The capacity to enable robotics and automation in manufacturing is a notable feature of 3D bonding technology [6]. To rephrase, the primary step is now just picking out the components and arranging them in a mould; the shoe is then made in a flash following the injection of polymer.

Multi-robot systems

Handling flexible parts and achieving more accurate piece positioning are driving factors in the wide use of multi-robot systems in industry. Due to their capacity to effectively fulfil these requirements, dual-arm robots are gaining significance in this context. To make use of a dual-arm robot for a pick-and-place job, for example, one arm can be stopped while the other follows a predetermined path [7]. The most efficient method, however, involves moving both arms at once; this cuts down on wait times and boosts system performance. The strategy of moving both arms simultaneously provides another level of complexity to the planning process because of the potential for collisions.

In order to incorporate numerous robots into manufacturing processes, several research areas are working on algorithms. A method for assigning tasks to multiple robots using greedy algorithms and particle swarm optimization [8]. Minimizing multitasking time, discovering a near best solution for collaborative scheduling and effectively maintaining load balancing of robot resources, are the goals of this study to enhance the resource usage of heterogeneous multi-robots. An optimization strategy for multiple objectives in a setting

with multiple robots performing different tasks [9]. A robot's energy utility function is defined and built as part of the process.

A reference trajectory optimization process was created for industrial tasks involving dual-arm robots [10]. Since they share the same work workspace, both arms must constantly monitor the other for potential obstacles and adjust their course accordingly. An examination into a method for optimising robotic manipulation in the face of obstacles [11].

Research on robotic systems for pick-and-place has been extensive so far. An extensive electronic card assembly facility's-controlled system was subject to the authors' investigation of the machine sequencing operation problem, which was implemented using routing heuristics [12], [13], [14]. To provide the best sequential pick-and-place devices and reduce feeder movements, PCB tables, and robot assembly times, it was suggested in that the dynamic Chebychev pick-and-place method be used for a triple objective function [15]. An iterative hybrid local search algorithm can also be used to solve the problem, and it finds a relative optimal solution fast [16].

In order to control robotic manipulators in non-repetitive trajectories, the authors [17] of create a free model iterative learning control (ILC) method. In pick-and-place operations, the model is checked. Along similar lines, a control system for fuzzy sliding mode variables to optimize pick-and-place operations for speed [18].

A modular system for the coordination of motion and the sequencing of robotic tasks for multi-arm systems [19]. A new approach, based on the regularized problem of multi-arm RTSPs, is presented in the dual-arm RTSP (Robotic Task Sequencing Problems) module. In order to solve the main problem, it breaks it down into smaller ones using a clustering-based algorithm. While other researchers [20], [21] has concentrated on task sequence planning with an assembly orientation, presents a dual arm approach that takes environmental constraints into account. The task was developed using the following method: the binary functions, the Gaussian Mixture Model, and the Monte Carlo method.

Optimization along a trajectory

Robot manipulator trajectory planning with time optimization has been the subject of extensive research. This problem has multiple proposed solutions.

An updated mathematical model for the food industry's pick-and-place method [22]. Optimizing the overall distance covered by the robot in operation was achieved by the

Hungarian algorithm. Using a greedy algorithm for calculating smooth trajectories in short time and forward speed planning offer a solution to an identical problem [23], [24]. The Genetic Algorithm (GA) and a Travelling Salesman Problem (TSP) form the basis of the strategy [25], [26]. In order to increase efficiency in the pick-and-place method, these methods attempt to determine the optimal piece sequence.

Learning the optimal trajectory for the robot is an area of focus for some research. To enhance robot manipulation tasks learning efficiency, a hybrid imitation learning (HIL) framework was utilised [27]. This framework combines state cloning (SC) and behavioural cloning (BC) methods.

As discussed in the research of Goldberg and Holland, another method involves the application of genetic algorithms (GA) [28], [29]. Aiming for optimize the trajectory in collaborative robots, a real-time method that combines simulation with genetic algorithms [30]. Transport time optimization with optimized trajectories is discussed. In addition, the heuristic method is used for delegate a series of tasks to various robotic systems by giving each task the setup that is perfectly suited to it in an assignment optimization module [31].

The issue of real-time evaluation and optimization of pick-and-place task performance has, indeed, received little attention in the academic literature. Nonetheless, this issue has been covered in a number of pertinent publications.

There is some discussion of creating an algorithm to execute the secure control task in image processing for real-time [32]. While pick-and-place tasks are not the primary emphasis of this work, the difficulty of completing tasks in real-time is addressed, which means it may be applicable to improving performance in this area.

By integrating real-time with the metaheuristic problem, the authors [33] enable each robot to carry out its designated pick-and-place method in real-time, thereby optimising throughput. While the exact algorithm and methodology employed are not disclosed, this study exemplifies a method that takes real-time performance optimisation into account.

Dual-arm robots

More and more humanoid robots are being developed to tackle the complexity and time constraints of industrial tasks. This has allowed for the automation of industrial tasks independently of their configuration. Because of this, bipedal and anthropomorphic robots have been the subject of a great deal of research recently. Coordination of the arms, route

planning in real-time to prevent constraints, and collisions required to accomplish the task successfully are some of the characteristics that complicate the dual-arm robots [34], [35].

A collaborative dual-arm model, an ABB YuMi robot, had 7 degrees of freedom (DOF) in all arms for a total of 14 DOF, is utilised in this study. The robot control and kinematic solution are discussed in two separate ways. In addition, the ABB YuMi is the subject of a detailed kinematic analysis, whereas a much involved control method regarding dual quaternions [36].

Shoe assembly using a pick-and-place method is the focus of this investigation. It employs a dual-arm robot to transport pieces and optimize the distance for pick-and-place by utilizing the simultaneous operation of both arms. When it comes to this context, some parts can be pick and place with just one arm, whereas the other parts, because of their size, need the cooperation of both arms. To optimize and automate the entire process, this study focuses on optimizing the trajectories and sequence in the robotic phase of the shoe production operation. Additionally, the 3D binding phase is highlighted as an integral part of the process that enhances automation and optimizes the assembly of the footwear.

The following is the basic outline of the article. Methodology and materials are provided in the following section, after Section 2.1 presents the necessary procedure and guidelines. The BILP-based mathematical model is laid out in Section 2.2, and the simulation results in Section 3 corroborate the method's viability and robustness. Section 3.3 introduced a comparison, and Section 3.1 and 3.2 presented and argued the overall results. Lastly, Section 4 provided some final remarks.

Methodology and materials

Creating the mathematical frame work for reduce the pick-and-place method distance follows a comprehensive outline of the research system. The research is conducted using the dual-arm collaborative robot ABB IRB14000, which is also referred to as YuMi [37]. The purpose of this robot's design is to assist human operators in manufacturing settings.

System overview

Accurate control is required when operating a dual-arm robot so that the arms do not collide with each other while sharing a single workspace area. This can only be accomplished

if the two arms' trajectories are in perfect sync and their movements are regulated to prevent potential collisions in real-time.

The arms are continually tracked to get positional data and, if needed, to recalculate the trajectory so that collisions are avoided. Additionally, reference points are established in the trajectory such that the two arms are synchronized to guarantee the proper transportation of arms that necessitate their usage. Pieces that need the use of dual arms can be correctly transported by adjusting the distance between the arms.

Mislocalization can have a negative impact on task performance in the setting of pick-and-place method, making calibration of camera accurate is important. Utilising non-linear iterative optimisation methods, the authors [38] suggest and develop a markerless hand-eye calibration technique tailored to the pick-and-place method. An ABB industrial camera is integrated into the vision system and fed into the robot to collect data for subsequent processing. The built-in vision programme can identify the various parts and ascertain their location in XY plane and orientation with respect to the Z axis. After the pieces were found and placed on the plane, the robot is instructed to pick and place them based on their position and orientation. An eye-in-hand camera, also called a wrist-mounted camera, is also a part of the YuMi robot. With this, viewing tasks are given more flexibility. The robot then executes a quality control process to ensure that each piece has been placed correctly after the pick-and-place method is finished. The wrist-mounted camera in robot is responsible for this function.

In this research, two distinct four-piece shoe models from various manufacturers are taken into consideration. One arm is sufficient for the first three pieces, but both are needed for the fourth piece. The mathematical model is tested by taking photocopies of each shoe at random positions. Based on past experiences, certain limitations have been set. The time it takes to complete piece 4 is added to the overall time it takes to complete the task because no other action can be done at the same time as carrying both arms. Furthermore, it had been resolved that the dual-armed piece shall inevitably be removed last. To retrieve a piece that is too far away for one arm to reach, one should typically use the arm that is closest to them.

The arrival of parts in the robot's work space initiates the picking and placing process in a manufacturing environment. To locate the pieces, the initial step is to take a photograph. The data is then transferred from the robot to a Python programme via socket

communication so that it can be processed externally. The optimal order for selecting and arranging the pieces is determined and communicated to the robot using a BILP algorithm. Following the order specified by the optimal sequence algorithm, the robot's pre-programmed paths are executed in order to avoid collisions.

Mathematical optimization problem

We apply a model that considers three parts that can be handled with a single arm and one part that can be handled with both arms to found a solution to the problem. The presence of three pick and place nodes is thus implied. The number of Cartesian plane nodes utilised to resolve the problem is eight, with an additional initial node added for all arms. Table 1 shown the summary of the notation utilized in BILP model.

Table 1 BILP model notation

M	The set of mould nodes (pieces) is cited. Every one of them is well-known for their specific position. The letter j will represent each node: 1, 2, 3.
T	The set of tray nodes (pieces) is cited. Every one of them is well-known for their specific position. The letter i will represent each node: 1, 2, 3.
S	In each case, it denotes the set of arms that are available. The letters s will stand for the following starting positions: 1, 2
K	Arms set is cited. An equal number of arms will be present. The letter k will stand for each arm: 1, 2.
D_{ij}	It is refer as the Euclidean distance among the two nodes i and j. The piece's position in the problem's Cartesian plane is used to calculate this distance. There is an additional movement j-i for every movement i-j, such that $D_{ij} = D_{ji}$. A positive value is required for all distances; distances among discordant nodes are not involved. The $3(s+p) + 2(s \cdot p)$ vector order, such that s be the quantity for robotic arms and p be the quantity of individual arm pieces that need to be moved.
X_{kij}	It is refer as binary variable. Each arm develops a different route depending on its value in the solution. Arm k will execute the sequence of steps defined by the i-j nodes, such that i be the starting and j be the ending points, if this variable is set to 1, meaning it is active. Conversely, this trajectory will not occur in the task if the value is 0.

Considering the robot's work workspace is essential during the pick-and-place method. For pieces with a rotation angle among 90° and 270° , a pre-rotation was required. This is due to the robot picks up pieces at an angle of about 3° relative to the XY plane. The robot's wrist may be unable to acquire the pieces if their pick-up point is angled at an angle that is not perpendicular to its work area.

Because arm collisions might result from an out-of-space rotation, this becomes particularly important when dealing with two-armed pieces.

Figure 1: Schematic of all possibilities. The home positions for each arm are denoted by S. The pick positions were represented by the i nodes and the place positions are represented by the j nodes

Figure 1 displayed a graph encompassing all possibilities for problems. The mandatory trajectories following the picking node visit are highlighted in black. Each possible trajectory is depicted in green. This issue is resolved through a (BILP) and it has numerous parts:

$$\min \sum_{k \in K} \sum_{i,j} D_{ij} X_{kij} \quad (1)$$

$$\text{s. t. } \sum_{i=1}^p X_{ksi} = 1 \forall k = s, k \in K, s \in S \quad (2)$$

$$\sum_{k=1}^2 X_{kij} = 1 \forall i = j, i \in T, j \in M \quad (3)$$

$$\sum_{j=1}^p X_{kjs} = 1 \forall k = s, k \in K, s \in S \quad (4)$$

$$\sum_{k=s=1}^2 X_{ksi} + \sum_{k=1}^2 \sum_{j=i} X_{kji} = 1 \forall i \in T \quad (5)$$

$$\sum_{i=j=1}^p X_{kij} \leq p - 1 \forall k \in K \quad (6)$$

$$\sum_{k=s=1}^2 \sum_{i \neq j} X_{kji} + \sum_{k=s=1}^2 X_{kjs} = 1 \forall j \quad (7)$$

$$\sum_{i \neq j} X_{kji} + X_{kjs} - X_{khj} = 0 \forall j \in M, k = s, h = j, h \in T \quad (8)$$

$$\sum_{j=1}^p X_{kji} + X_{ksi} - X_{kih} = 0 \forall i \in T, k = s, h = i, h \in M \quad (9)$$

Objective function (1): To transfer the individual parts from the tray to the mold, the objective function was described as the sum of overall distances run by dual arms. Hence, the function should be optimized by the optimization problem:

Constraints

- Initial constraints (2): The first node is where the arm must start. Hence, the route from the starting to the designated tray nodes $i \in T$ must be specified once. The number of type constraints will equal the number of arms (s).
- Placement constraints (3): All parts must go to a specific spot on the mold, so this motion can only be executed by a single arm. Even though some motions cannot be crossed by either arm, all movements can only be performed to the fullest extent with one arm. Constraints of the form p will exist.
- Returning the arm back to its initial position (4): After finishing the task, all arms must return to its home position (initial node s). In other words, each arm must go from a jth node to initial node s once. The number of type constraints will equal the number of arms (s).
- Only one visit is made to each tray node (5): Only one visit is made to each tray node $i \in T$. When accessing these nodes for the first time, they were reached from initial node $s \in S$. Alternatively, if they are to be reached after another piece, they can be reached from a node $j \in M$. Constraints of the form p will exist.

- In the event that a single arm is unable to select all pieces (6): The fact that one arm is unable to carry all parts is a criterion. Transferring parts between the two arms should, in theory, shorten the overall task time. The number of type constraints will equal the number of arms (s).
- A single arm emerges from every mould node (7): Each piece can only be placed at the $j \in M$ node, which means that each node can only be visited once when all arms are considered. After a piece has been positioned on a node by one arm, it cannot be removed by either that arm or the other. Constraints of the form p will exist.
- A node's entrance and exit from the mould (8): A mandatory arm is for an arm to depart from any placing node $j \in M$ and proceed to the first node $s \in S$ or next picking node $i \in T$ once it completes its process. Constraints of the form p will exist.
- A node's entry and exit from the tray (9): It is necessary for an arm to depart from a picking node $i \in T$ in order to reach the analogy placing node $j \in M$ for every arm that reaches that node. It is accessible either from the arm's starting node or from a node that was picked earlier. Constraints of the form p will exist.

Results and discussion

A total of 500 cases were evaluated, with 250 trays from Manufacturer 1 and 250 trays from Manufacturer 2 used for testing the model's feasibility. The three pieces were arranged in unorganised ways on each tray, but they were always within the robot's working area. This manner, all possible outcomes were considered.

Utilizing the lpsolve package, the R language was used to implement the BILP model. The case studied in this work has 27 constraints and is composed of 3 pieces and 2 arms.

Model results from Manufacturers 1 and 2

For every tray, the path of every arm is examined. Three trays from Manufacturer 1 were randomly chosen to show the arms' trajectory in Figure 2 (top row). Positioned at (250,0) is the robot's body, while S1 and S2 are its end effectors. The picking positions are represented by nodes $i1$, $i2$, and $i3$, while the place positions are represented by nodes $j1$, $j2$, and $j3$. The right arm trajectories are shown by the pink lines, and the green lines denoted the trajectories of left arm.

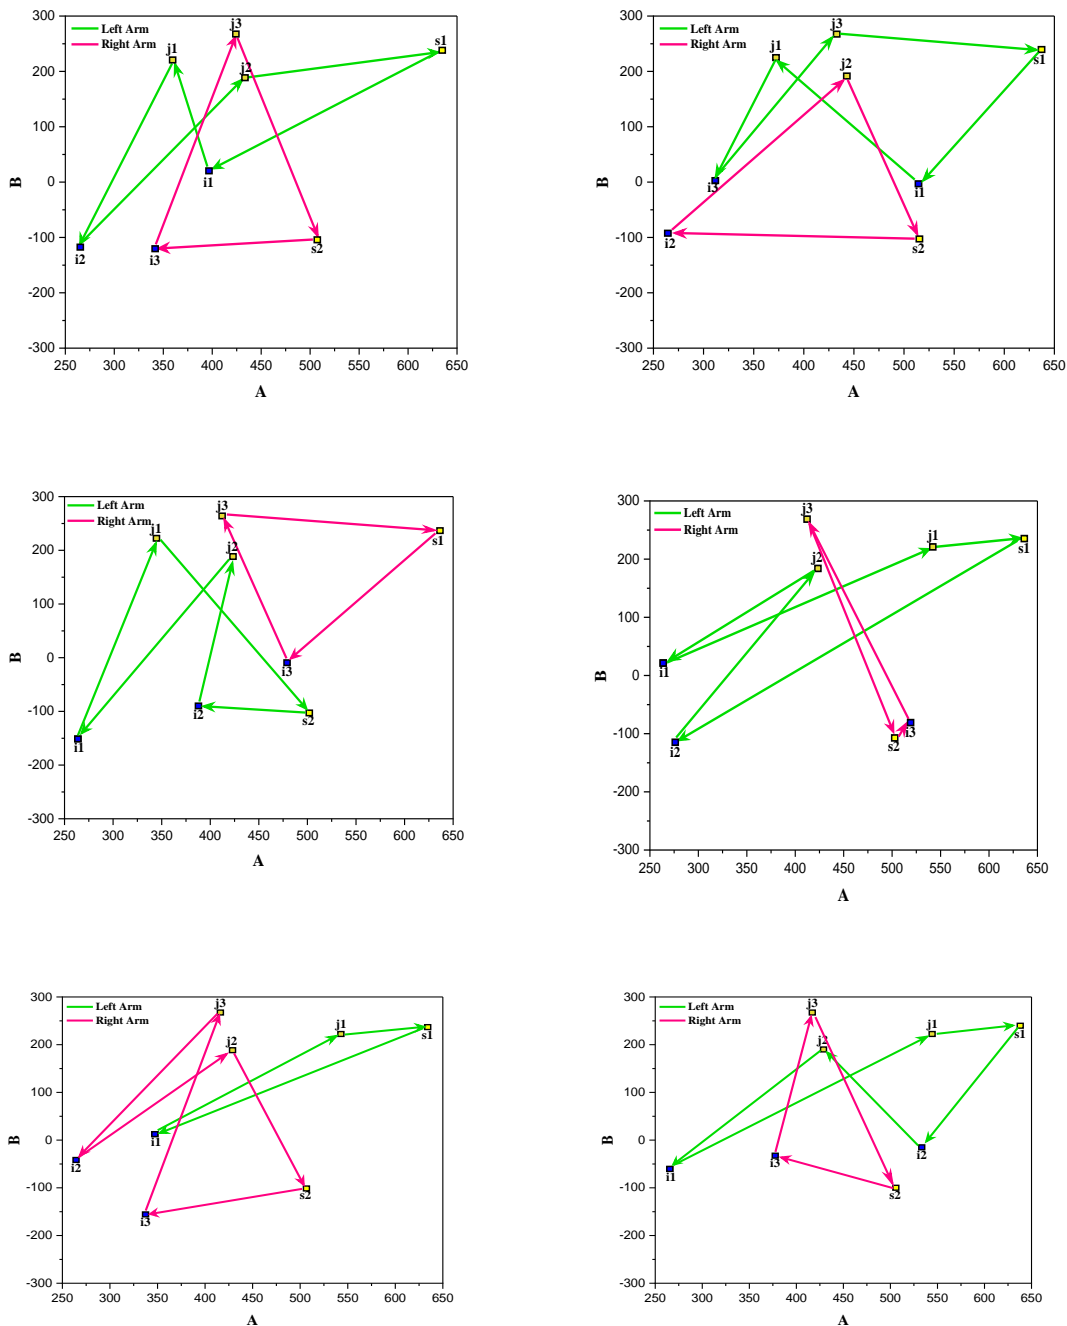

Figure 2: Best results for various pick positions from Manufacturer 1 and 2.

Three trays of the second model from Manufacturer 2, selected at random are shown in Figure 2 (second row) as solutions. The j1 node is where the most noticeable change occurs.

As illustrated in Figure 2, the robot programme employs two strategies to prevent conflicts and collisions while the trajectories are being executed. To avoid collisions, the first tactic is to set up synchronization points such that the two arms has to be placed at the same time. The alternative approach is to increase the speed of the arm that does the majority of the pick-and-place method. This way, both arms will begin and end their work at the same duration.

Figure 3 displays the results of an analysis of the data from the models developed by Manufacturers 1 and 2, with the analysis displayed in a boxplot and a density plot. A boxplot showing 50% of the central data for the Manufacturer 1 model is shown by the pink line, which also depicts the median at 1973.2 mm. Between 1952.1 and 1991.7 mm is the calculated 95% confidence interval, with a mean of 1971.9 mm. The dispersion of the overall distances for all trays is shown in the density plot. It is evident that the majority of the data is concentrated in a minimum period, which indicates that the model is robust.

Figure 3: Two manufacturers' boxplots and density graphs

Both the Manufacturers 1 and 2 models produce comparable results. The range for the 95% confidence interval is 1930.8 to 1965.9 mm, including a mean of 1948.4 mm and a median of 1971.9 mm. The bulk of the data falls within the 1900 to 1980mm range, identical to the Manufacturer 1 model.

It is clear from comparing the two models that they are similar in some respects and that they both consist of three pieces. Each model's key data is summarized in Table 2. Because piece 1 is in a different spot in the fitting task, the median and mean values are slightly

different. The Fabricator 2 model, on the other hand, exhibits less dispersed data and more clustering. The absolute values differ at the 95% confidence interval, although the interval is quite small. This proves that the model is stable, since most of the data decreases within this interval.

Table 2 Characteristics of the best sequence for Manufacturers 1 and 2

	Manufacturer 1	Manufacturer 2
Mean	1977.2	1953.7
Median	1978.5	1977.2
SD	165.2	146.7
Minimum	1639.8	1568.8
Maximum	2361.7	2226.1
95% CI	1957.4 - 1997.0	1936.1-1971.2

As previously mentioned, when comparing the two boxplots with their 95% confidence intervals, the data is more compact in the second model compared to the first, and the ot values are higher because the placement of piece 1 is different in all models.

Computational Time

Time required to calculate the optimal sequence is a crucial factor to think about because the model would be useless if the time required to discover the quickest sequence outweighs the benefit gained from using it instead of a random sequence. Consequently, the computational cost must be considered.

Time required to calculate the best sequence for both manufacturer 1 and 2 models is displayed in Fig. 4, which is a box plot. An outlier of 0.04s exists in the Manufacturer 2 model, although it does not deviate significantly from the average. According to the graph, most of the data for both trays falls within the range of 0.03s when calculating the sequence. For the first manufacturer's model, the average time is 0.0201s, while for the second, it's 0.018s. These timings corroborate the optimal sequence calculation speed for both manufacturer 1 and 2 models, giving support to the suggested solution's efficacy.

Figure 4: Boxplot of computational time for Manufacturers 1 and 2.

The main features of both models are displayed in Table 3. The model of Manufacturer 1, for example, has the median time of 0.0200s, an mean time of 0.0201s, the maximum time of 0.0500s, the minimum time of less than 0.0001s, and the Sd of 0.0102s. Manufacturer 2 had a Sd of 0.0075s, a maximum time of 0.0400s, an mean duration of 0.0181s, a minimal duration of 0.0100s, and a median duration of 0.0200s. A low Sd indicates that the data from the Manufacturer 2 model is more compact, which is clearly appreciated.

Table 3 Comparison of Computing Time (in seconds) for Two Manufacturers

	Manufacturer 1	Manufacturer 2
Mean	0.0312	0.0291
Median	0.03	0.03
SD	0.0212	0.0085
Minimum	0.0001	0.01
Maximum	0.06	0.05

Figure 5 shows the results of an analysis that attempts to determine whether the model exhibits a logarithmic, linear, or exponential behaviour by plotting the computational time against the rise of the trays analyses. Using both models, the analysis was created. Thus, in order to determine the optimal sequence, both models exhibit linear behaviour with respect to the time values that are comparable.

Figure 5: The computational cost for both models as a function of the number of trays

Due to the reduced mean time of 0.025 seconds required to determine the optimal sequence for placing 3 pieces by pick-and-place method, this data gives support to the conducted research.

Comparison of the decision tree (DT) model with BILP model

A DT model developed to optimize process execution time is presented in the article [39]. This model helps to minimize computational cost by reducing all feasible sequences to the finite tree branches.

In order to compare two models, the best sequences were chosen for the DT model in simulations 13 (where the left arm picks up piece 1 and the right arm picks up pieces 2 and 3), and 17 (where the right arm picks up piece 3, the left arm picks up piece 1, and the right arm picks up piece 2) respectively. Using the identical placements of the pieces in the tray, the researchers next determined the BILP model's arm travel distance.

Figure 6 displays the data, which compares the BILP model's distance estimation to the actual arm travel times for all manufacturers and simulations. When the distance travelled is equal, the pink line indicates the midpoints among the two models.

(a) Analysis of the Manufacture 1 model using Simulation 13 and the BILP technique

(b) Analysis of the Manufacture 1 model using Simulation 17 and the BILP technique

(c) Analysis of the Manufacture 2 model using Simulation 13 and the BILP technique

(d) Analysis of the Manufacture 2 model using Simulation 17 and the BILP technique

Figure 6: Comparison of the DT model with the BILP model

In simulation 13, the mean distance covered for the Manufacturer1 model is 2111.1 mm, with a Sd of 163.8 mm. There is a Sd of 156.6 mm and mean distance of 2148.3 mm in simulation 17. In simulation 13, the average distance travelled by the Manufacturer 2 model is 2128.4 mm, with a Sd of 147.86 mm. There is Sd of 171.4 mm and mean distance covered of 2173.5 mm in simulation 17.

According to the findings, for Manufacturer 1, the BILP model increases the mean distance covered per tray by 9.0 %, and for Manufacturer 2, it improves it by 11.6 %. The benefits and efficacy of the BILP model in minimising on pick-and-place distances are shown by these results.

This new method considerably shortens the time it takes to execute tasks with almost no computational cost, and it also proves that the DT based approach is valid. Minimizing the

number of paths needed for a two-arm robot to load the mould with all the pieces was feasible.

Make note that about 83% of a shoe's total assembly time is devoted to the pick-and-place method. When compared to the DT model, this suggested method achieves a total time reduction of about 7.1% and 9.0%. According to the DT model, the mean times for Manufacturers 1 and 2 are 15.14s and 15.51s, respectively. There is a 1.5s start time and a 5s end time, on top of the pick-and-place process. The combined runtime for the Manufacturer 1 model is 21.64s, while the Manufacturer 2 model clocks in at 22.01s.

Assuming that the Manufacturer 1 model takes the mean of 21.64s to handle a mould, and that A dual-arm robot is capable of handling 1,308 moulds in a single 8-hour shift, the overall assembly time of all trays were decreased about 42.46 mins using this model. Thus, it indicates that the suggested BILP model could allow for the simultaneous assembly of 171 extra moulds for Manufacturer 2 and 129 extra moulds for Manufacturer 1 within the same time frame.

Every single point in Figure 6 is located above the pink line using the DT model, it appears that the amount of movement is consistent. In terms of distance minimization, the BILP model consistently outperforms the decision tree model.

n-piece BILP model

It was discovered that rising the pieces number to achieve the best sequence presented a problem after the mathematical model for optimizing the sequence of pick-and-place had been discovered. Due to the presence of loops between the two pieces, the corresponding arm was unable to achieve its final position. The following constraint was decided to be introduced into the model to stop these loops and guarantee proper execution.

$$\sum_{j=1} X_{kij} + \sum_{j \neq 1} X_{kij} < p \forall i \in T, k = s, j \in M \quad (10)$$

Loops (10). A closed loop connecting two pieces cannot be generated by means other than returning to or beginning at the initial position. constraints of the form 3(p-2) are required. The algorithm's robustness was tested for 4, 5, 6, and 7 pieces. The best possible outcome was achieved in every instance after 250 trays were manufactured. Each case's graph of a tray's sequence is shown in Figure 7. The left arm is represented by the green line and the right arm is denoted by the pink line.

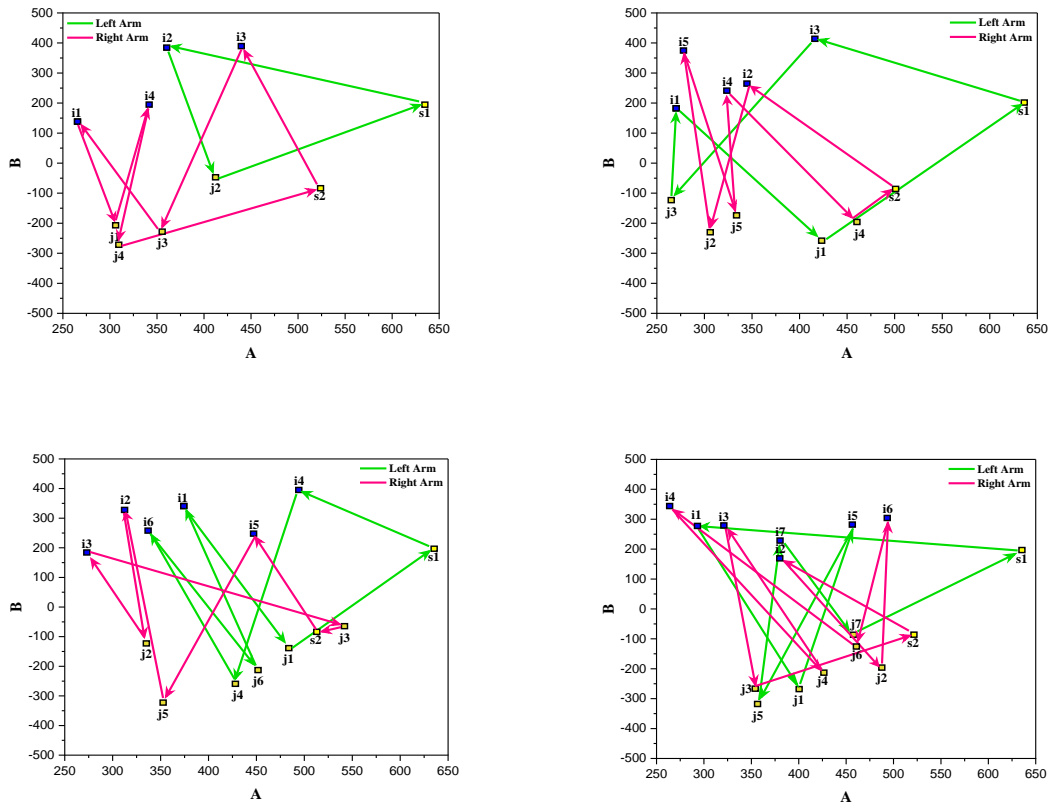

Figure 7: Best results of various number of pieces a) 4, b) 5, c) 6 and d) 7.

As shown in Figure 8, the computational cost and mean optimal distance were derived from the analysis performed for various numbers of pieces. Since there is an exponential rise in the number of constraints as the number of pieces rises, the computational time also grows exponentially [40]. Conversely, as the increase in number of pieces, the ideal distance follows a proportional function.

Conclusions

Utilizing a double-arm combined robot, this article exhibits the outcomes of BILP model for pick-and-place method in shoe production. Simplifying the multi-robot model is one of the key benefits of the suggested method. Two distinct shoe models were tested; one involved picking up three pieces with a single arm, and the other required the use of both arms. The model was successfully tested with over 500 cases, each of which yielded an optimal trajectory for both arms. Note that the two-arm piece is included in the total time and is thus evaluated last in this research. The mathematical model does not incorporate this component due to the reasons mentioned earlier. Pieces that can be grasped by a solitary arm are the primary emphasis of the model. As a result, the average distance moved by the model from Manufacturer 2 is 4327.5 mm, whereas the model from Manufacturer 1 moves 4185.9 mm. The shift in piece 1's location is the primary cause of this distance discrepancy.

The success achieved with 500 trays proves that the model is highly reliable. There was no data discovered outside of the workspace, and all trajectories were calculated at its best, yielding better results. The amount of time required to identify the best sequence is another critical consideration. The results demonstrate that each tray takes the mean of 0.02s to calculate. As the number of trays increases, this time grows in a linear fashion. Hence, the suggested method is advantageous since the model takes very little time to find the optimal sequence. The DT model is compared to the BILP model, which demonstrates the

enhancement in distance minimization at a much lower computational cost. During the pick-and-place method, the BILP model either surpassed or tied the distance covered by the robotic arms in all of the displayed trays.

After evaluating the current BILP model with the suggested two models, the following step is to examine it with models that have more pieces. This will help determine if the results were applied to any model, including other systems that use pick-and-place method. Additionally, a BILP model offered in this research is robust against changes brought about by adding or removing robots because the quantity of robots were treated as a parameter. At last, the model was evaluated with n pieces of data, confirming its robustness; the computational time grows in exponential as the number of pieces rises, while the optimized distance grows proportionally.

ABSTRACT

The study explores the performance of diverse lattice structures fabricated through Fused Deposition Modeling (FDM) in additive manufacturing. Lattice structures offer unique mechanical properties, impacting strength, flexibility, and weight. This research aims to investigate and compare the performance of different lattice configurations. The methodology involves the creation of varied lattice designs using FDM technology with distinct parameters, including infill density, cell size, and pattern types. Subsequently, mechanical tests are conducted to evaluate their performance under different loading conditions. Through comprehensive analysis, the study assesses factors such as structural integrity, load-bearing capacity, and deformation characteristics exhibited by each lattice structure. Finite element analysis (FEA) might complement experimental data to predict and validate structural behavior. The findings aim to contribute insights into identifying optimal lattice configurations for specific applications, considering trade-offs between strength, weight, and material usage. Understanding the mechanical behavior of these structures is crucial for industries like aerospace, automotive, and biomedical

engineering, where lightweight yet robust components are essential. In conclusion, this investigation endeavors to provide a comprehensive understanding of the mechanical performance of various lattice structures manufactured through FDM. The results seek to guide engineers and designers in selecting and customizing lattice designs based on the desired functional requirements, enabling the fabrication of efficient and optimized components in additive manufacturing processes.

INTRODUCTION

Additive manufacturing is the process of creating an object by building it one layer at a time. It is the opposite of subtractive manufacturing, in which an object is created by cutting away at a solid block of material until the final product is complete. Technically, additive manufacturing can refer to any process where a product is created by building something up, such as moulding, but it typically refers to 3-D printing. Additive manufacturing was first used to develop prototypes in the 1980s — these objects were not usually functional. This process was known as rapid prototyping because it allowed people to create a scale model of the final object quickly, without the typical setup process and costs involved in creating a prototype. As additive manufacturing improved, its uses expanded to rapid tooling, which was used to create Molds for final products. By the early 2000s, additive manufacturing was being used to create functional products. More recently, companies like Boeing and General Electric have begun using additive manufacturing as integral parts of their business processes.

LITERATURE REVIEW

Shivank A. Tyagi, Manjaiah M “Additive manufacturing of titaniumbased lattice structures for medical applications” Additive manufacturing (AM) has made it possible to manufacture intricate lattice structures, especially for metal-based techniques like laser powder bed fusion (L-PBF) that are best suited for developing complex structures. These controlled lattice structures have numerous applications,

particularly in the biomedical field, where they are used to improve cell adhesion and proliferation for implants. Wenjin Tao, Ming C. Leu “Design of lattice structure for additive manufacturing” Additive Manufacturing (AM) technology provides new opportunities to automatically and flexibly fabricate parts with complicated shapes and architectures that could not be produced by conventional manufacturing processes, thus enabling unprecedented design flexibilities and application opportunities. The lattice structure possesses many superior properties to solid material and conventional structures. Asliah Seharing, Abdul Hadi Azman et al , “A review on integration of lightweight gradient lattice structures in additive manufacturing parts” This review analyses the design, mechanical behaviours, manufacturability, and application of gradient lattice structures manufactured via metallic additive manufacturing technology. By varying the design parameters such as cell size, strut length, and strut diameter of the unit cells in lattice structures, a gradient property is obtained to achieve different levels of functionalities and optimize strength-to-weight ratio characteristics.

Problem Identification

Additively manufactured lattice structures are popular due to their desirable properties, such as high specific stiffness and high surface area, and are being explored for several applications including aerospace components, heat exchangers and biomedical implants. The complexity of lattices challenges the fabrication limits of additive manufacturing processes and thus, lattices are particularly prone to manufacturing defects. The review focuses on the effects of lattice design on dimensional inaccuracies, surface texture and porosity. The design constraints on lattice structures are also reviewed, as these can help to discourage defect formation. Appropriate process parameters, post-processing techniques and measurement methods are also discussed.

Types of Technologies

Fused Deposition Modelling :

Fused Deposition Modelling (FDM) revolutionizes 3D printing by building objects layer by layer through the controlled deposition of thermoplastic filaments. In this additive manufacturing process, a heated nozzle meticulously extrudes the material in a precise pattern, enabling the creation of intricate three-dimensional structures. FDM is renowned for its accessibility, cost-effectiveness, and versatility, supporting various thermoplastics like ABS and PLA.

STEREOLITHOGRAPHY (SLA)

Stereo lithography (SLA) stands as a pioneering additive manufacturing technique, utilizing a laser to solidify liquid photopolymer resin layer by layer, constructing intricate 3D objects with remarkable precision. In the SLA process, the UV laser selectively cures the resin, solidifying it into a cohesive structure. Renowned for its ability to produce high-resolution prototypes with exceptionally smooth surfaces, SLA is a go-to technology for applications requiring fine details and accuracy. SLA finds extensive use in industries such as product design, dentistry, and jewelry, where intricate models and highly detailed components are essential.

SELECTIVE LASER SINTERING (SLS)

Selective Laser Sintering (SLS) is an Additive Manufacturing (AM) technique that fabricates three-dimensional objects by selectively fusing powdered material, typically polymers or metals, layer by layer using a high-power laser. In the SLS process, a powdered material bed is evenly spread, and the laser selectively sinters or fuses the powdered particles together based on a digital model's cross-section, solidifying one layer before the next layer is added.

Electron Beam Melting (EBM)

Electron Beam Melting (EBM) stands as an advanced Additive Manufacturing (AM) process that fabricates complex metal parts through the precise melting of metal powder layers using an electron beam. In EBM, a high-energy electron beam scans and selectively melts the metallic powder bed, following a 3D digital model's blueprint. The process occurs within a vacuum to prevent oxidation and ensure

uniform melting. layer by layer, the electron beam fuses the metal powder, solidifying it into a desired shape without the need for support structures. EBM's highenergy beam allows for rapid melting and solidification, enabling the creation of intricate and robust components with excellent material properties.

Introduction to Lattice Structure

A lattice is a three-dimensional arrangement of ions or atoms in a crystal. Latticing enables you to reduce solid mass without compromising on performance. Using a shell and lattice infill approach, 50% or higher weight reductions are not uncommon. Less material also reduces manufacturing costs, making production with additive manufacturing economically viable. It is possible to manufacture simple lattices using traditional manufacturing methods like CNC machining, welding, or casting. For example, the core of the sandwich panels used on an aircraft's skin is a honeycomb structure manufactured by welding together thin strips of aluminum. However, additive manufacturing allows you to directly print structures with high complexity and inherently small features more cost-effectively.

Applications

Lattice structures have many applications

Lightweighting: One of the most significant benefits of lattice structures is their ability to lighten objects' weight while maintaining structural integrity.

Lightweighting has become crucial in many industries because lightweight objects consume less energy and are more cost-effective and sustainable.

Energy absorption: Lattice structures' exceptional energy absorption properties are another critical benefit. This makes them ideal for impact-absorbing materials like helmets and body armor; lattices help distribute the energy of an impact more evenly, reducing serious injury risk in these types of products. Lattices can also be used for vibration dampening and noise absorption in various applications.

Thermal management: Lattice structures are also incredibly effective at managing heat. Their unique design creates a large surface area for heat dissipation, making them ideal for thermal management applications, such as heat exchangers.

Osseointegration: In the medical field, lattice structures are used to create customized patient implants to fit the exact shape and size of a patient's unique anatomy, improving the success rate of surgeries and shortening recovery times. Lattices' porous structure also allows for the integration of cells and tissues, promoting bone and tissue growth that hastens the healing process.

CONCLUSION

The comprehensive performance study conducted on diverse lattice structures manufactured through Fused Deposition Modeling (FDM) in Additive Manufacturing illuminates the intricate interplay between design intricacies, material compositions, and printing parameters, yielding crucial insights into their mechanical behavior. In conclusion, this comprehensive investigation offers valuable insights into the multifaceted nature of lattice structures manufactured via FDM Additive Manufacturing. It provides a foundation for further advancements, encouraging continued research in optimizing lattice designs and material combinations for enhanced performance across various industrial domains.

ABSTRACT

Copper-graphene composites have emerged as promising materials for various engineering applications due to their exceptional mechanical, electrical, and thermal properties. In this study, we explore the fabrication of copper-graphene composites via powder metallurgy and investigate their mechanical characteristics. The incorporation of graphene into copper matrix is aimed at enhancing the mechanical performance while maintaining good electrical conductivity. The fabrication process involves the dispersion of graphene nanoplatelets within copper powder using mechanical mixing techniques followed by compaction and sintering. Various weight percentages of graphene ranging from 0.5% to 5% are examined to evaluate their influence on the mechanical properties of the composites.

Microstructural analysis using scanning electron microscopy (SEM) reveals uniform distribution of graphene within the copper matrix, indicating effective interfacial bonding. X-ray diffraction (XRD) analysis confirms the presence of graphene and its interaction with copper lattice, suggesting potential reinforcement mechanisms.

The mechanical properties of copper graphene were evaluated through nanoindentation and tensile testing, demonstrating enhanced mechanical strength

and flexibility compared to pure copper. Thermal conductivity measurements using the laser flash technique exhibited excellent thermal transport properties, indicating the potential for heat dissipation applications.

INTRODUCTION

Copper graphene, a composite material composed of copper and graphene, has garnered significant attention in recent years due to its unique properties and potential applications. Graphene, a two-dimensional allotrope of carbon with remarkable mechanical, electrical, and thermal properties, when combined with copper, a widely used industrial metal known for its excellent conductivity, can create a material with enhanced performance characteristics. This synergy between graphene and copper opens up new avenues for applications in various fields such as electronics, energy storage, catalysis, and more.

Once the copper-graphene mixture is prepared, it undergoes a consolidation process. Consolidation can be achieved through methods such as spark plasma sintering (SPS) and ball milling followed by sintering. During consolidation, the copper particles bond together, forming a dense structure while retaining the graphene reinforcement.

The investigation of the properties of copper graphene involves understanding its structural, mechanical, electrical, and thermal attributes to exploit its full potential in practical applications. This study aims to delve into the fundamental properties of copper graphene through experimental analysis, theoretical modeling, and computational simulations. By elucidating the underlying mechanisms governing its behavior, researchers can tailor the material's properties to suit specific application requirements.

Overall, the investigation of copper graphene holds promise for advancing materials science and engineering, offering solutions to existing challenges and paving the way for innovations in various technological domains.

LITERATURE REVIEW

This chapter provides details about the recent work and findings for the successful fabrication of copper- graphene composites. Every work is reviewed in detail. A lot of literature is available for preparing copper-graphene composite. Some of the few recent pieces of literature with copper-graphene composite and its behavior along with powder metallurgy route are discussed.

This chapter has been prepared based on the following subtitles.

Cu based composites

Graphene addition of composites

Cu with Graphene based composites

The researchers have been studying and carried out research on Copper Matrix Composites (CMCs) and given the specific properties like Processing Methods of Metal Matrix Composites high specific strength, high fatigue and creep resistance. Moreover lower thermal expansion and high wear resistance render them suitable for use binuclear components; special integrated circuit chips packages for spacecraft, etc. These components are produced commercially from MMCs.

(M. Aravind 2022)

The cold upset metal matrix composites have higher hardness compared to sintered composites due to geometric work hardening and pileup of dislocations. Addition of graphite increases the lubrication and thereby decreasing Strain hardening

(Iyaraja Karuppiah 2017)

In various industrial applications, copper based MMCs are used. The selection of suitable reinforcement combinations and processing routes are chosen to meet the demand. Cu MMCs are widely used in electrical contact applications like brushes in electric motors and generator.

(Nayak 2013)

synthesized copper-graphene composite through friction stir casting technique and reported hardness improvement by 40% compared with pure Cu. They claimed that the improved result was aided with the uniform distribution of graphene with Cu. Singh et al. (2019) proposed a new technique for preparing copper-graphene composite using 3D printing and 9 pressure less sintering methods.

(Reddy al.2020)

OBJECTIVE OF THIS WORK

The most important objectives of this thesis are to study the Cu-GNS composite through the flake powder metallurgy technique and to study the effect of sintering on the mechanical properties of the composite. The key objectives of this work are to examine the effect of sintering factors and graphene content in copper-graphene composite fabricated by powder metallurgy route and to study mechanical strength and wear behaviour. The detailed objectives are as follows:

To fabricate Cu-GNP composite using flake powder metallurgy technique.

To fabricate Cu-GNP composite without agglomeration of GNS.

To study the behaviour of Cu-GNP composite under different sintering conditions.

To find the optimal sintering condition to attain good quality Cu-GNP composite.

To study the mechanical properties such as density, hardness and compressive strength with respect to sintering parameters.

Powder Metallurgy

Powder metallurgy is the easiest, efficient, economical method to prepare graphene reinforced composites.

Powder metallurgy also includes manufacture and processing of non-metal powders to products, which exhibit metallic properties such as iron carbide based magnetic materials (ferrites), sintered corundum for machining and forming, few types of semiconductors etc. Powder Metallurgy process is economical on the basis of its lower energy consumption, higher material utilization and reduced numbers of process steps, as compared with other production technologies such as stir casting method, hot forging techniques, molecular level mixing process, spark plasma sintering process and high-pressure torsion method. Cu-graphite Metal Matrix Composites (MMCs) are prepared by conventional powder metallurgy route using conventional and Spark Plasma Sintering (SPS) techniques. Spark plasma sintering shows better response to densification and hardening than conventional sintering.

Structure of graphene Nano sheet

Graphene, a two-dimensional allotrope of carbon, possesses a unique atomic structure that contributes to its remarkable properties. The structure of graphene can be described as a single layer of carbon atoms arranged in a hexagonal lattice resembling a honeycomb pattern.

Layer by layer Assembly

Layer-by-layer a simple and flexible method used for preparing graphene reinforced metal matrix composites. This process takes place by placing graphene layer by layer on a substrate. By this process, bulk materials fabrication is not possible and only nano materials can be synthesized.

Ball Milling

The ball milling process will be used to reduce the matrix (Cu) and reinforcement material Mg particle size. The required quantities of the powders were exactly weighed with an electronic weighing scale to prepare different composites. The mixing was done in a planetary ball-milling machine at a speed of 300 rpm for a duration of 3 hours. 10 mm diameter tungsten carbide balls to be used in the high energy ball mill and 20:1 weight ratio of ball to charge to be maintained. The blending process will be done at the planetary ball mill.

Sintering Process

The sintering time and temperature were tentatively fixed. Trials will be conducted by varying the sintering time and temperature both above and below the reference parameter. The produced green composite specimen were loaded into a furnace for sintering process. Sintering will be done in an electric box furnace for a period of 4 hours at a temperature of 900°C. These sintered composites will be allowed to cool inside the furnace to room temperature. The box furnace and sintered.

CONCLUSIONS

Powder metallurgy technique is one of the well-recognized composite manufacturing with attractive properties such as low density, high stiffness, high compressive strength, and high resistance to corrosion and chemicals.

The incorporation of graphene into copper enhances its mechanical properties, such as tensile strength and hardness, making it a promising material for various applications requiring durability and resilience.

Copper graphene exhibits excellent thermal and electrical conductivity, attributed to the high conductivity of both copper and graphene components, which could be advantageous in electronics and thermal management systems.

ABSTRACT

The successes of machining operation in machine tool depend on the experience and skill of the machine operator. A significant amount of work has been done on the machine to be controlled by computer. The on-line control serves as the key to this problem. This pilot study also emphasizes the important of interface design between machine operator, computer, and the machine tool. The designed controller will ease the integration work of the three elements mentioned above. Another significant study carried out is the software element. The software has the features to understand the G-code and the M-code of the Computerised Numerical Controlled machine.

In this project involves the retrofitting of CNC turning centre motion controller to windows-based USB motion controller. Retrofitting refers to the addition of new technology or features to older systems. When we say that retrofitting related to some component that mean we try to upgrade that component and improve their efficiency through a present technology.

Now a days 'CNC' controllers are manufactured using modern technology which employs a communion of computer software, hardware, and firmware. The present CNC controller is used in the CNC turning machine controller is obsolete, it is RS232

communication, MS-DOS based CNC operating software. The availability of spares, service and MS-DOS operating system is not available. The up gradation of the CNC controller is expensive. This project aims to develop and retrofit CNC turning machines with low-cost USB motion controller and open-source CNC controller software. It allows a quick and easy adaptation of new components to integrate the machine tool. It provides a low-cost alternative to solve problems, approximately 10 times below the original CNC up gradation cost, the machine will be available for teaching and learning of CNC technology.

INTRODUCTION

CNC turning centre retrofitting and up gradation refer to the process of upgrading or modernizing existing CNC (Computer Numerical Control) turning machines to enhance their performance, accuracy, efficiency, and capabilities. This is done by incorporating newer technologies, components, software, and automation systems into the existing machine structure. The goal of retrofitting and upgrading a CNC turning centre is to improve its productivity, reduce downtime, increase accuracy, and extend its overall lifespan.

Key aspects of CNC turning centre retrofitting and up gradation include:

Hardware Upgrades:

This involves replacing or upgrading mechanical components such as spindles, ball screws, bearings, and tooling systems to improve precision, speed, and durability.

Control System Upgrade:

Upgrading the control system includes installing newer CNC controllers with advanced features such as faster processing, better programming capabilities, improved tool management, and enhanced connectivity options.

Software Enhancement:

Updating or installing new software can improve programming efficiency, introduce new machining strategies, optimize tool paths, and integrate with CAD/CAM systems for seamless workflow.

Automation Integration:

Retrofitting may include integrating automation solutions such as robotic loading/unloading systems, automatic tool changers, bar feeders, and part measurement systems to enhance productivity and reduce manual intervention.

Safety and Ergonomics:

Upgrading safety features such as enclosures, sensors, and interlocks improves operator safety, while ergonomic enhancements like adjustable workstations and control panels enhance user comfort and efficiency.

Networking and Connectivity:

Upgraded machines often feature networking capabilities for data monitoring, remote diagnostics, and integration with Manufacturing Execution Systems (MES) for real-time production monitoring and management.

Overall, CNC turning centre retrofitting and up gradation enable manufacturers to stay competitive by leveraging the latest technologies, improving machine performance, reducing operational costs, and meeting evolving industry demands.

LITERATURE REVIEW

When discussing the CNC machining is necessary for several reasons, and its widespread adoption is driven by the numerous advantages it offers in the field of manufacturing. Here are some key reasons why CNC machining is considered essential:

This study discusses the retrofitting of CNC machine tools, including turning canters, to enhance performance and functionality. It covers aspects such as upgrading control systems, replacing worn-out components, and integrating automation for improved productivity (S.Gopalakrishnan 2010).

The paper focuses on the enhancement of CNC machine performance through retrofitting, with a specific emphasis on turning centers. It explores the benefits of hardware and software upgrades, automation integration, and their impact on machining efficiency (A. Rajaraman 2015).

This research highlights the modernization and up gradation of CNC turning machines through retrofitting strategies. It covers topics such as control system upgrades, tooling advancements, and the integration of Industry 4.0 technologies for smarter manufacturing.

(R. Singh 2018)

The study investigates the benefits of automation and control system up gradation in CNC turning centers. It discusses the role of advanced control algorithms, real-time monitoring, and adaptive machining strategies in improving overall equipment effectiveness (OEE).

(M. Gupta 2019)

This case study evaluates the impact of retrofitting on CNC machine tool performance, including turning centers. It analyses before-and-after data to quantify improvements in accuracy, cycle time reduction, and overall production efficiency.

(T. Chatterjee al.2020)

Integration with CAD/CAM Systems:

CNC machines seamlessly integrate with computer-aided design (CAD) and computer-aided manufacturing (CAM) systems, streamlining the design-to-manufacturing process and reducing the likelihood of errors.

Adaptability to Changing Designs:

In industries where design changes are frequent, CNC machining allows for quick adjustments to the machining program, facilitating rapid adaptation to evolving design requirements. CNC machining is necessary for modern manufacturing due to its ability to deliver precise, repeatable, and efficient production processes across a wide range of industries. It has become a cornerstone technology in the fabrication

of components and products in sectors such as aerospace, automotive, medical, electronics, and more.

Standard features include:

Three stepper drive outputs, with control for a fourth external stepper axis.

Integral AC/DC power supply

Point to point moves, software cams and gearing.

24 general purpose 5V digital inputs, software configurable as level or edge triggered.

16 general purpose digital outputs (open collector Darlington type)

2 differentials $\pm 10V$ angle inputs with 12-bit resolution.

OBJECTIVE OF THIS WORK

The objectives of a CNC (Computer Numerical Control) machine vary depending on the specific application and industry. However, some common objectives associated with CNC machines include:

Precision Machining:

Achieving high levels of accuracy and repeatability in the machining process.
Consistent and precise production of parts to meet design specifications.

Efficiency and Productivity:

Increasing production speed and throughput. Reducing cycle times for machining operations. Minimizing downtime through efficient tool changes and setup procedures.

Flexibility:

Adapting to different machining tasks and part geometries without the need for extensive retooling. Handling various materials and part sizes.

Automation:

Automating repetitive tasks to improve efficiency and reduce the need for manual intervention. Allowing for lights-out manufacturing, where the machine can operate without constant human supervision.

Cost Reduction:

Minimizing material waste through optimized cutting paths. Reducing labour costs associated with manual machining. Enhancing tool life and reducing the frequency of tool changes.

Quality Control:

Ensuring consistent part quality through precise control of machining parameters. Implementing features like tool and work piece probing for in-process quality checks.

Complex Geometries:

Enabling the production of intricate and complex part geometries that would be challenging or impossible with manual machining.

Programming and Software Integration:

Streamlining the CNC programming process to create efficient tool paths. Integrating with CAD/CAM software for seamless design-to-manufacturing workflows.

Tool Management:

Efficiently managing and monitoring tool usage, including tool wear and replacement. Implementing tool change strategies to optimize machining operations.

Safety:

Implementing safety features to protect operators and prevent accidents. Ensuring that the machine operates within specified safety standards and guidelines.

Maintenance:

Minimizing downtime through proactive maintenance scheduling. Monitoring machine health and performance for early detection of potential issues.

Breakout Board CNC USB MACH3 Features:

Support for 4-axis connection, which can connect four stepper motor units or servo drives.

The maximum step-pulse frequency is 100KHz, which is suitable for servo or stepper motor.

Supports automatic probe tool.

Supports emergency entry.

Supports limit switch.

Support to connect the electronic steering wheel

You need to use an external 24V DC power supply to isolate the USB and external port, and to make the system more stable.

It has a 0-10V output port, you can use mach3 software to control the spindle motor speed.

commonly used inputs, you can connect the limit switch, estop switch, probe switch, reset to zero, and other devices.

commonly used isolated relay output interface, can drive four relays to control spindle start, turn forward and turn back, pumps and other devices

Status LED indicates connection status on the board.

Setup Installation:

Computer is interfaced with breakout board through USB port and the software is installed. Settings are done as per the datasheet. STEP and DIRECT connections are connected to all axis motor drivers and axis motor terminals relate to the corresponding motor driver. All axis limit sensors are connected to breakout board as feedback. Spindle motor is connected to spindle driver and VFD signal is connected.

CONCLUSION

Overall, this study contributes to the retrofitting of a CNC lathe machine is to improve the existing CNC lathe machine to provide the new features of CNC machine such as up gradation.

Modification of CNC controller communication from RS232(serial port) to USB communication

Up gradation of CNC controller firmware compatible with latest windows versions,

Up gradation of CNC control software with simulation from MS-DOS to latest windows versions,

Up-gradation Package is less expensive and more readily justifiable with very lower cost than a new CNC Lathe machine.

ABSTRACT

The paper presents a hydropower plant system using a hydraulic centrifugal pump, which is an eco-friendly and pollution-free solution for remote areas where power transmission is not yet possible. The centrifugal pump increases the head of underground water by lifting it from low to high head, ensuring continuous power generation and less maintenance. This system does not require an external energy source and makes free energy available for existing hydropower plants. The hydraulic centrifugal pump works with underground water and a water, making it suitable for remote areas with less power requirements. Although the installation is high, the running cost is low. Overall, the study demonstrates the feasibility and effectiveness of utilizing hydraulic centrifugal pumps and hydroelectric generators in remote locations. The results provide valuable insights for improving water circulation and energy production in areas with limited resources.

INTRODUCTION

Energy sources are valuable for their abilities to generate electricity, heating and other necessities of industrial & commercial life and modern home requirements. While conventional forms of energy, which includes fossil fuels and nuclear energy, have supplied most of the world's electric power for the past century, a recent focus on climate change and energy independence has raised interest in unconventional forms of energy, many of which emits less carbon and is renewable. Our project topic is based on the use of hydro power energy to convert it as electric energy so as to use it for various commercial, industrial and home requirements.

Hydroelectric power is important to our Nation. Growing populations and modern technologies require vast amounts of electricity for creating, building, and expanding. In the 1920's, hydroelectric plants supplied as much as 40 percent of the electric energy produced. Although the amount of energy produced by this means has steadily increased, the amount produced by other types of power plants has increased at a faster rate and hydroelectric power presently supplies about 10 percent of the electrical generating capacity of the United States. Hydropower is an essential contributor in the national power grid because of its ability to respond quickly to rapidly varying loads or system disturbances, which base load plants with steam systems powered by combustion or nuclear processes cannot accommodate. Reclamation's 58 power plants throughout the Western United States produce an average of 42 billion kWh (kilowatt-hours) per year, enough to meet the residential needs of more than 14 million people. This is the electrical energy equivalent of about 72 million barrels of oil. Hydroelectric power plants are the most efficient means of producing electric energy. The efficiency of today's hydroelectric plant is about 90 percent. Hydroelectric plants do not create air pollution, the fuel--falling water is not consumed, projects have long lives relative to other forms of energy generation, and hydroelectric generators respond quickly to changing system conditions. These favourable characteristics continue to make hydroelectric projects attractive sources of electric power

LITERATURE REVIEW

Machine which, since set in function, continues to function perpetually without supplying any energy. The question about the perpetual motion machine is one of the issues, which attracts people who tend to believe strange things and occultism. That's why such ideas are adopted from various non-recognized religious circles which often describe in their books or in their speeches perpetual motion machines, which however have neither been manufactured nor have functioned.

Small hydro power and Micro Hydro are simply the best proven renewable energy harvesting technologies we have in today's date. As mentioned in previous article this site has great potential to produce electric power. According to our study this plant can be design up to 27 kW and such small generation will be possible on any water purification plant and sewage treatment plant. If suppose this power generation unit is designed for 1 kWh then it would save up to of the plant. Though these things are really minor to that of today's energy crisis but such initial spark may give valuable contribution in energy recovery program which are being executed by our government. (Nikhil P Patrike et al.,2012)

The basic purpose of this research is to establish a fundamental basis for further work and developments in the field of wave energy. In this research, a model of wave energy is fabricated whose sole purpose is to extract the energy from waves. The efficiency of this fabricated wave power plant is 35% and the rpms of shaft are 200. More over this technique of extraction of energy from waves will be provide emission free, sustainable and decentralized system of energy. (M. Saqlain Abbas et al., 2015)

Nowadays requirements for energy continue growing more and more because of population growth and the rapid development of technology. Many countries have serious problems with supply regarding energy, especially for green energy. There are still many countries in the world that don't have electrification. Many places in World have good potential for developing mini hydropower plants; Investment in a

mini hydropower plant is not that high and period of turnover is shorter when compared with other alternative sources, the investment costs increase drastically by increasing penstock diameter but energy losses decrease (Shpetim Lajqi et al.,2016)

Small hydropower (SHP) technology should be popularized for rural areas, industrial estates and standalone electrification provision rather than the national grid. To boost power sustainability, countries of sub-Saharan Africa need to build human and infrastructure capacities that will support the local manufacturing of SHP plants and components in the region. Increase in local contents in the manufacture of SHP equipment will reduce the cost of power projects as against the present cost situation (Williams S. Ebhota et al 2016)

Hydroelectric power has an important role to play in the future, and provides considerable benefits to an integrated electric system. The world's remaining hydroelectric potential needs to be considered in the new energy mix, with planned projects taking into consideration social and environmental impacts, so that necessary mitigation and compensation measures can be taken. Clearly, the population affected by a project should enjoy a better quality of life as a result of the project. Hydro development should go hand in hand with further research and development in the field of other renewable options such as solar and wind power. Energy conservation measures should also be optimized and encouraged.

The working of the unit is very much satisfactory and we can avoid the corrosion. It gives steadiness and good performance due to the metal precision. The demo cost is high; if it is implemented on the buildings, wastage water Pipelines cost will be reduced. If we want more power generation, the choice is accepted by the Pelton wheel. Turbine for changing the dynamo and nozzle. We can able to change the size and Structure for Pelton wheel due to its speed increases. This is the main advantages of the Pelton wheel turbine using wastewater (P. Viswabharathy et al., 2017)

From the conceptual general design of the hydropower plant, a micro-Pelton wheel turbine based on the available head and flow rates that will be operated

through pumped-storage technique was selected. Then, the turbine section has been designed to have eight turbine buckets that contain the curved reflectors. From the analytical calculations, the functionality of the designed micro-hydropower plant is evaluated, which the results indicate the design is able to deliver the required electrical power to the farm with high overall efficiency. From the feasibility study, it was proven that the project is economically feasible based on the small value of the simple payback period. Applying this project will help to decrease the dependency on conventional energy sources and open the local market and people to the renewable energy sources. (Rubanprakash et al., 2017)

The project was to design and develop a small size turbine concept to utilize and generate electricity-using water stored in the overhead tanks of a residential building. This also deals with alternative manufacturing process using 3D printing, which utilizes FDM technique. An optimization methodology is developed for the design and the development of Pico hydro turbine runner blade using 3D Solid Works modelling. The calculations were made as per the generation of approximately 12W power using water from an overhead tank. (Nasr Al Khudhiri et al., 2018)

Hydropower is the best renewable source of energy among all other renewable sources of energy and it is an economical, non-polluting, and eco-friendly electro power generating system. By taking the advantage of falling water due to gravity electricity is being produced. Hydropower generates the energy of around 24% of the world's total energy. Hydro-electric power is more consistent than the solar power generation system as it produces electric power in day & night time also unlike solar power which can produce only in the day time. (Mr. Prasanna Nayak H et al., 2019)

The electric power developed by small water-falls, tributaries, and rivers in micro-hydro power generation systems are capable of producing an output power up to 5-6 KW, enough to supply a rural community village which has small electricity

consumption. This system does not consume any fossil fuels hence, the hydropower generation system does not contribute to the depletion of fossil fuels also in pollution. (Singh, K.V et al., 2015)

The hydropower plant works on the principle in which the potential energy of water in the reservoir is converted into kinetic energy which is further converted into electrical energy with the help turbine, generator, etc. some of the major component HPP are Dam or reservoir, penstock, turbine, generator, prime mover. Some micro-hydroelectric power generation plants are reversible, in that water is used again for power generation, pumped from the lower reservoir to the upper reservoir by using electricity when demand is low. (Fortaleza N. B et al., 2018)

Whenever a demand is high reversible pumped hydro storage consumes external energy so the efficiency of hydropower plants decreases as the input energy is increasing. n WORLD PUMPS July/August 2018Hydro-electric plant control K. Elissa, "Title of paper if known," unpublished.

To overcome this problem, we have to go for alternative energy resources in which energy is generated naturally like solar energy, wind energy, etc. The hydraulic ram pump is working on the kinetic energy of falling water and can be used as a small hydropower plant to pump the water at the desired elevation. (Jaupi O et al., 2017)

WORKING PRINCIPLE

The self electricity generator water turbine working layout is shown in figure. the major components including radial turbine, electric generator, water pump, power system and machine frame are indicated in the figure. Turbine setup is attached in the machine frame and the generator is connected with belt drive to the turbine shaft. Flywheel is connected to the turbine shaft. water pump is mounted in the machine frame and the nozzle is positioned on top of radial turbine.

Initially the turbine needs to rotated manually by operator and the with the help of flywheel it keeps required force for the next rotation. Flywheel act as an energy resorvoir and helps to continuous rotational motion. When the turbine rotates, the

generator also rotates due to the belt drive connectivity. Generate used to produce electricity and that energy is used to run the water pump. water runs the turbine with the help of water pump and nozzle. Again this process repeat itself continuously. Addition some electric devices (fan, light, etc.,) are connected to the power system to verify the energy output.

RADIAL TURBINE

A turbine is a rotary mechanical device that extracts energy from a fast-moving flow of water, steam, gas, air, or other fluid and converts it into useful work. A turbine is a turbo-machine with at least one moving part called a rotor assembly, which is a shaft or drum with blades attached. A Pelton turbine to be selected for this power generation process.

A Pelton turbine or Pelton wheel is a type of hydro turbine used frequently in hydroelectric plants. The Pelton wheel is an impulse turbine in which vanes, sometimes called buckets, of elliptical shape are attached to the periphery of a rotating wheel. These turbines are generally used for sites with heads greater than 300 meters. Lester Pelton created this type of turbine during the gold rush in 1880. The water in a Pelton turbine is moving quickly (high velocity head) and the turbine extracts energy from the water by slowing the water down, which makes this an impulse turbine.

When used for generating electricity, there is usually a water reservoir located at some height above the Pelton turbine. The water then flows through the penstock to specialized nozzles that introduce pressurized water to the turbine. To prevent irregularities in pressure, the penstock is fitted with a surge tank that absorbs sudden fluctuations in water that could alter the pressure.

The Pelton wheel turbine is a tangential flow impulse turbine used for high heads of water and Lester Allan Pelton, an American Engineer, invents it. The energy available at the inlet of the turbine is only kinetic energy. The pressure energy at the inlet and outlet of the turbine is atmospheric. This is a hydraulic turbine and the main uses of these turbines are in the hydropower plant to generate electricity.

WATER PUMP (2-HP Pump)

A centrifugal pump is one of simplest rotating equipment in any process plant. Centrifugal pump may be single stage (one impeller) or multistage (multiple impeller) and can be horizontal split or barrel type or vertical type. Higher the delivery/discharge pressure required more the number of impellers will be needed. In centrifugal pump, energy is imparted to the fluid in form of velocity or kinetic energy and which is then converted into pressure energy of the fluid that is being pumped.

AC GENERATOR

A generator is a device that converts motive power (mechanical energy) into electrical power for use in an external circuit. Sources of mechanical energy include steam turbines, gas turbines, water turbines, internal combustion engines, wind turbines and even hand cranks. British scientist Michael Faraday invented the first electromagnetic generator, the Faraday disk, in 1831. Generators provide nearly all of the power for electric power grids.

WATER SUMP (Reservoir)

A water tank is a container for storing water. Water tanks are used to provide storage of water for use in many applications, drinking water, irrigation agriculture, fire suppression, agricultural farming, both for plants and livestock, chemical manufacturing, food preparation as well as many other uses. Water tank parameters include the general design of the tank, and choice of construction materials, linings.

Various materials are used for making a water tank: plastics (polyethylene, polypropylene), fiberglass, concrete, and stone, steel (welded or bolted, carbon, or stainless). Earthen pots also function as water storages.

NOZZLE

A nozzle is a device designed to control the direction or characteristics of a fluid flow (especially to increase velocity) as it exits (or enters) an enclosed chamber or pipe. A nozzle is often a pipe or tube of varying cross sectional area, and it can be used to direct or modify the flow of a fluid (liquid or gas). Nozzles are frequently used to control the rate of flow, speed, direction, mass, shape, and/or the pressure of the stream that emerges from them. In a nozzle, the velocity of fluid increases at the expense of its pressure energy. The water coming from the reservoir through penstock is accelerated to a certain velocity by means of a nozzle. It is used to increase the kinetic energy of water which is used to strike the buckets attached to the runner.

PLANT FRAME STRUCUTRE

Structural steel is a category of steel used as a construction material for making structural steel shapes. A structural steel shape is a profile, formed with a specific cross section and following certain standards for chemical Composition and mechanical properties. Structural steel shapes, sizes, composition, strengths, storage practices, etc., are regulated by standards in most industrialized countries. Structural steel members, such as I-beams, have high second moments of area, which allow them to be very stiff in respect to their cross-sectional area.

The shapes available are described in many published standards worldwide, and a number of specialist and proprietary cross sections are available.

LAYOUT OF MODEL

CONCLUSION

Hydropower is a popular renewable energy source for producing electricity on both local and large scales, as it produces no hazardous waste or greenhouse gases. However, the small hydroelectric industry has room for growth and requires urgent changes to attract investments and support sustainable businesses. Government support is crucial for creating a favourable and inclusive ecology for small

hydropower plants. The main objective of the self-generated electricity generation water turbine is to provide clean, sustainable electricity with minimal impact on natural and renewable resources. Governments should be natural partners in this industry. The future is promising, and the small hydro industry is expected to flourish with government support. One of the most significant outcomes is the generation of environmentally friendly, sustainable electricity, with 150 watts being sufficient for household essentials in areas with scarce electricity. Recirculation technology allows for extended operation without water filling, providing rural families with electricity for extended periods.

ABSTRACT

Firework industry effluent, rich in nutrients but containing harmful heavy metals, poses a significant environmental threat. Cyanobacteria, capable of thriving in such environments, offer a potential solution for wastewater treatment and bioremediation. Additionally, the food industry's reliance on artificial colorants necessitates exploring natural alternatives preferred by health-conscious consumers. Cyanobacteria samples were isolated from various sources and cultured in BG11 medium and effluent. The isolate demonstrating optimal growth (SL03) was identified using microscopic and 16S rRNA gene sequencing. The effluent was characterized, and SL03 was cultivated in 10 l of effluent for biomass collection. Solvent extraction isolated secondary metabolites from the biomass, followed by chromatography (TLC, HPLC) for purification and identification. Characterization of the extracted pigment involved UV-Vis, FTIR, and MS techniques. Cyanobacteria isolate SL03 grown in effluent exhibited promising growth. Solvent extraction yielded a pigment successfully purified and characterized. This study demonstrates the feasibility of cultivating cyanobacteria in firework industry effluent for natural food colorant production. The isolated and characterized pigment presents a potential sustainable alternative to synthetic food additives. Future research will focus on optimizing growth conditions, scaling up pigment production, and conducting safety assessments for food industry applications.

DEGRADATION OF POLYETHYLENE USING BACTERIA

ABSTRACT

Plastic pollution has become a pressing environmental concern, prompting the exploration of innovative solutions such as bacterial degradation of polyethylene. Understanding the growth kinetics and degradation mechanisms of PVS1 is essential for elucidating its efficacy in addressing plastic pollution. Polyethylene, a widely used plastic, poses a significant environmental threat due to its non-biodegradable nature. Bacterial degradation offers a promising avenue for breaking down polyethylene into simpler compounds. The growth kinetics analysis of PVS1 reveals an initial increase in bacterial growth, indicating its adaptation to the polyethylene substrate. Subsequent decline in growth suggests the depletion of nutrients or accumulation of inhibitory factors, influencing the degradation process. These dynamics highlight the complex interplay between bacterial activity and environmental conditions during polyethylene degradation.

Fourier-Transform Infrared Spectroscopy (FTIR) analysis provides insights into the structural changes induced by bacterial degradation. Lower intensities observed in the FTIR spectra of treated polyethylene samples compared to controls suggest alterations in polymer composition. This corroborates the efficacy of PVS1 in initiating molecular-level changes within the polyethylene matrix. The isolation and characterization of PVS1 from a plastic-contaminated environment highlight the abundance of microbial resources for bioremediation efforts. The observed growth kinetics and structural changes in polyethylene induced by PVS1 underscore the efficacy of bacterial isolates in initiating degradation processes.

ABSTRACT

Food contamination and spoilage, stemming from microbial activity and oxidative reactions, pose considerable challenges for the food industry, leading to financial setbacks, environmental concerns, and health hazards. Despite rigorous quality control measures, packaged foods are susceptible to quality degradation due to environmental influences, packaging discrepancies, and human errors within the industry. The pH fluctuations within the product can arise from various factors such as exposure to air, inadequate pasteurization, temperature variations during storage and packaging defects. These challenges necessitate innovative solutions. Hence, this investigation focused on utilization of seaweed derived polysaccharide (agar) beads infused with natural anthocyanin for reliable deterioration detection.

Agar extracted from *Gelidium* sp. through acid-alkali treatment serves as a primary source of high 3,6-anhydro-L-galactose and low sulfate content, resulting in high-quality agar that enhances integrity and strengthens the gelation process. Anthocyanin pigment extracted from *Hibiscus rosa sinensis* petals using ultrasonication-assisted methods and used to infuse with agar to determine endpoints through color changes during acid-base variation. The pigment compound immobilized in the agar bead provides real time assessment of colour change due to food quality loss. Further study on characterization was done by UV-Visible spectrum, Fluorescent spectrum analysis and FTIR. The solubility test and pH colour change on acid base titration indicates the conformity of stable choice of product. These results indicate a promising solution for real-time monitoring of food quality. The distinctive colour-changing characteristics, broad pH sensitivity range, natural, cost-effective and potential health advantages render anthocyanin infused with agar is an ideal candidate to develop smart indicator in packed foods.

These findings present a promising solution for the continuous monitoring of food quality, utilizing agar polysaccharide beads embedded with anthocyanin markers. This approach effectively addresses challenges related to microbial contamination and oxidative reactions, offering a cost-effective and reliable method for ensuring food integrity and safety.

ABSTRACT

Protein structure prediction plays a crucial role in understanding protein function and designing targeted therapeutics.

However, recent advancements in deep learning, exemplified by AlphaFold, have revolutionized this field.

In this study, we employed AlphaFold, a state-of-the-art deep learning model, to predict the structure of Cyclin dependent kinase 20 (CDK20) from the species *Saimiri boliviensis boliviensis* (Bolivian squirrel monkey).

Utilizing sequence-based and evolutionary information, AlphaFold accurately predicted the three-dimensional structure of CDK20 with high confidence.

The predicted structure provides valuable insights into the function and regulation of CDK20, facilitating further research and drug discovery efforts targeting this important kinase.

RESULT

We could encompass the accuracy of the predicted structure, any key insights gained from the predicted structure, and the implications of these findings for understanding the function and regulation of Cyclin dependent kinase 20 (CDK20).

Additionally, prediction methods could be mentioned to highlight the reliability and robustness of the AlphaFold predictions.

Characterization and seed growth promoting effect of co-compost produced through biotransformation of sugarcane and ash gourd residues for sustainable waste utilization

ABSTRACT

Co-composting involves biodegradation of different organic residues to promote production of organic nutrient rich manure for effective biotrash management. The present study deals with biotransformation carried out by co-composting of discarded organic biotrases: sugarcane residues and peel segments of Ash gourd; analyzing the biotransformation process using spectral techniques and seed growth promotion effects. The co-composting process reached thermophilic temperature of 43.9 °C to promote successful biodegradation of the organic matter. Spectral analysis revealed significant variations in the transformation process. In particular, CIELAB analysis depicted changes in the color co-ordinates especially in the L * values from 65.56 to 39.65 indicating the increase in the darkness of the organic matter due to humification process. FTIR analysis showed comparable variations in the intensity of the peaks: O-H /N-H stretch of alcohols/phenols (3309 cm⁻¹ to 3289 cm⁻¹); C-O stretch of alcohols, carboxylic acids, esters, ethers (1028.84 cm⁻¹ to 1031.73 cm⁻¹) as a result of biotransformation. UV-vis analysis showed the photometric ratio (A₆₆₄/A₄₇₂) value of 4.2 confirming good maturity levels. Stereo microscopic analysis depicted the change of morphological feature of the organic matter from creamy white to brownish black particles. The mature compost tested for seed growth promotion effects has identified concentration dependent effects with maximum growth of root (7.83 ±1.82 cm) and shoot (7.07±2.25) observed in 0.4 % concentration of the co-compost in green gram. Hence, it is summarized that co-composting of ash gourd peel with sugarcane residues could be effective to produce manure for usage in organic farming.

ABSTRACT

Recent advancements in pharmaceutical research have illuminated the vast potential of algae-derived secondary metabolites in addressing pressing health concerns. This paper presents a comprehensive review of the diverse applications and therapeutic potential of these bioactive compounds. Algae, including both macroalgae and microalgae, offer a rich source of secondary metabolites with varied biological activities, such as antioxidant, antimicrobial, and anticancer properties. Through advanced extraction techniques and innovative methodologies, researchers have enhanced the efficiency of obtaining these bioactive compounds, paving the way for their translation into pharmaceutical products. The paper explores the characteristics and sources of algal secondary metabolites, highlighting their structural diversity and ecological functions. Furthermore, it delves into novel methodologies for extracting and isolating these compounds, along with screening techniques for identifying their therapeutic potential. Additionally, the therapeutic applications of algae-derived secondary metabolites are elucidated, including their roles in cancer treatment and prevention, anti-inflammatory and antioxidant effects, antimicrobial and antiviral activities, and neuroprotective effects. Moreover, the eco-friendly sourcing and sustainability aspects of algae-based pharmaceutical compounds are discussed, emphasizing their renewable nature and minimal environmental footprint compared to traditional drug sources. The paper concludes by underscoring the importance of continued research and investment in this field to unlock the full potential of algae as valuable resources for drug discovery, ultimately benefiting both human health and the environment.

ABSTRACT

Ruellia patula is a medicinal plant in Ayurvedic pharmacopeia, found in India, Southeast Asia, America, and Sub-Saharan Africa. In the present study, we investigate anti-bacterial activity, anti-oxidant activity and wound healing of ethanol extracts of *Ruellia patula*. by using various organic solvents including ethanol, methanol, chloroform, acetone and water. The bioactive compounds examined by GC-MS were export for the further docking studies. The agar well diffusion method and DPPH, hydrogen peroxide and ferric cyanide was used to assess the anti-bacterial activity and anti-oxidant of different crude extracts obtained from the leaves. Meanwhile, anti-inflammatory activity was evaluated by the cell line study of IL-6. According to the results of this investigation, leaf extracts can effectively cure bacterial infections and in favour of using it in traditional medicine.

INTRODUCTION

For centuries, plants have been used for a wide variety of purposes, including the treatment of infectious diseases (Kuruppu et al., 2019). According to the World Health Organization, approximately 80% of the world's population, mostly in developing countries, still relies on medicinal plants for primary health care (Sakkas and Papadopoulou, 2017).

Many plants have been studied because of their bioactive properties and great anti-oxidant potential. Anti-oxidants reduce oxidative stress in cells and have therefore become useful in the treatment of many human diseases like inflammatory diseases (David et al., 2019).

Considering the above plants *Ruellia patula* species belonging to Acanthaceae family is chosen in this study. Acanthaceae family commonly known as Punichedi in Tamil. It is a hairy small under shrub, found in Arabia, Africa, India (especially in Southern India), Sri Lanka, and Myanmar. The plant is commonly distributed on the wastelands in Tamil Nadu, India. Its leaves are used for treating syphilis, insect bites, eye diseases, skin diseases, gonorrhea, tumors, rheumatic complaints renal infection, cough, wounds, scalds, toothache, stomachache, and kidney stones problems (Facchini, 2001; Goldman, 2001). *R. patula* Jacq has significant anti-bacterial and anti-inflammatory activities (Bhuvaneswari and Manivannan, 2014). Considering the foregoing this study was to determine the anti-bacterial effectiveness of leaf extracts of *R. patula*.

Materials and Methods

The disease-free plants *Ruellia patula* was collected from the surrounding of Sivakasi (Latitude – 9.6632282° and Longitude – 77.782576°), Virudhunagar District, Tamil Nādu, India Fig. 1. The plant species were identified in Department of Botany, Ayya Nadar Janaki Ammal College, Sivakasi, Tamil Nādu.

CHARACTERIZATION

Fourier Transform Infrared Spectroscopy (FTIR) of leaf extract

The ethanol extracts were grinded separately with the KBr pellets and analyzed on a shimadzu model. To know the different functional groups, present in the extracts. The spectra were recorded in the region of 400 - 4000 cm^{-1} at a resolution of 4.0 cm^{-1} . Background correction was made using a reference blank KBr pellet (Devi and Battu, 2019).

GC-MS analysis of leaf extract

The leaf extract of was analyzed by GC-MS instrumentation. Gas chromatography study includes the important optimization process such as introduction of sample extract onto the GC column, separation of its components on an analytical column and detection of target analysis by using mass spectrometry (MS) detector. 5 ml of ethanol extract was evaporated to dryness and reconstituted into 2 ml methanol. The extracts were then subjected to GC-MS analysis (Shazhni et al., 2018).

Molecular docking of leaf extract

The energy minimized 3D structures of bioactive compounds identified from ethanol extract of *R. patula* were docked with the TRPV1 (Transient receptor potential cation channel subfamily V member 1) and the chemical compounds were acted as ligand molecule. The docking study was performed for four compounds. The effectivity of these compounds can be determined via the docking studies by calculating their energy minimization value. The compounds Protein Data Bank (PDB) file were downloaded from drug bank. After that the docking control, parameters and models to display where set to the receptor and ligand molecule. The output was set to predict 200 solutions. The final docked structure is completely energy minimized with lowest energy conformation. The lowest energy minimized value is the most suitable for drug stability (Menaga et al., 2021).

The 3D structure of ethanol extract of *R. patula* were docked with the TRPV1 GC-MS compounds were analysed and retrieved from PubChem database. Then these 2D structures were converted into 3D structures with the help of using smiles translator tool and further minimization of energy performed with reported structure. The lead compounds were minimized by computing gasteiger charges and saved. PDBQT file format (Menaga et al., 2021; Hoque et al., 2019). Based on Lipinski's rule of five, a drug scan was carried out to find

whether the final selected ligand compounds have the pharmacological properties. The structural details and the smiles notation of the selected five compounds were retrieved from PubChem / Drug bank database. The structures were determined by the online Smiles Translator tool. The Smiles notation of all the compounds was obtained from Drug bank, and PubChem were subjected to an online Smiles Translator tool to generate PDB and energy minimized 3D structure file. Geometry optimization and energy minimization were achieved following the successful construction of the structures of bioactive chemicals as ligands (Menaga et al., 2021).

Anti-bacterial Activity

Anti-bacterial properties of ethanol extract of *R. patula* L. against the bacterial cultures were determined by using Kirby Bauer method. Nutrient agar was prepared and autoclaved at 121°C for 20 mins at 15 lbs. Then the microbial cultures were *E.coli*, *Bacillus*, *Staphylococcus*, *Shigella* and *Pseudomonas*. These cultures were kept in the freshly prepared nutrient broth and kept in a shaker at 37°C for 24 hours. The nutrient agar was prepared and sterilized by autoclaving the medium and the plates. The sterilized medium was poured in the thickness of 10mm. 20µl of bacterial culture spread over the media using sterile L rod. Each well should be cut 6mm in diameter. The plant extracts were poured on the marked wells whereas the solvent used for extract serve as negative control whereas the antibiotic ampicillin was act as a positive control. The zone of incubation was measured and tabulated (Ibrahim and Kebede, 2020; Auchaogu and Igara, 2021).

Anti-oxidant activity

The anti-oxidant activity of the plant extracts were determined on the basis on their scavenging activity of the stable 1, 1- diphenyl-2-picryl hydrazyl (DPPH) free radical, hydrogen peroxide free radicals and ferric cyanide assay (Alabri et al., 2014; Baba and Malik, 2014; Guchu et al., 2020).

In vitro Anti-inflammatory study

Inhibition of albumin denaturation

500 µl of 1% bovine serum albumin w added to 100 µl of plant extract. This mixture was kept at room temperature for 10 minutes, followed by heating at 51°C for 20 minutes. The

resulting solution was cooled down to room temperature and absorbance was recorded at 660 nm. Acetyl salicylic acid was taken as a positive control. The experiment was repeated three times and the percentage of inhibition of protein denaturation was determined according to the formula:

$$\% \text{ Inhibition} = 100 - ((A1 - A2) / A0) \times 100$$

where A1 represents sample absorbance, A2 represents product control absorbance and A0 represents positive control absorbance (Mizushima and Kobayashi, 1968; Sakat et al., 2010).

Membrane stabilization assay

Anti-coagulated human blood was collected and centrifuged at 3000 rpm for 10 min. The obtained solution was washed three times with saline. RBC layer was collected and diluted to make 10% v/v using 1X phosphate buffer saline (PBS) followed by the method of Sakat et al., (2010).

Proteinase inhibition assay

100 µl of BSA mixed with 100 µl of extract and incubate at room temperature for 5mins. Then add a 250 µl of trypsin and centrifuge. The supernatant was collected and absorbs using UV visible spectrometry at 210nm. Acetyl Salicylic acid used as control (Sakat et al., 2010).

Anti-proteinase assay

The reaction mixture contains 0.06 mg trypsin, 1ml of 20mM Tris HCl buffer and 1 ml of the test sample. This reaction mixture was incubated at 37°C for 5mins. Then add 0.8% of casein. And the set up was incubated for 20 min, add 2 ml of 70% perchloric acid was added to terminate the reaction. Then the sample was kept into the centrifuge and the cloudy suspension was obtained. Tris HCl buffer used as a blank. And supernatant of the sample was read at 210nm. The experiments were done triplicated (Sakat et al., 2010).

Cell line study

Measurement of IL-6 Cytokines by ELISA

Human peripheral blood was collected from the healthy volunteers in 3.8% sodium citrate-treated tubes in accordance with established institutional guidelines. Briefly,

mononuclear cells were isolated by layering peripheral blood onto Lymphocyte Separating Medium (LSM). The leukocytes enriched buffy coat containing the mononuclear cells were collected and the presence of erythrocytes was removed by lysing with 1% RBC lysis buffer (Sudeep et al., 2017).

The PBMC cells (1×10^6 cells/ml per well in a basal medium) were seeded into a 6-well tissue culture plate and pre-treated with 100 $\mu\text{g}/\text{ml}$ of test sample followed by stimulation with 1 $\mu\text{g}/\text{ml}$ of LPS. The plate was incubated at 37°C with a 5 % CO_2 incubator for 24 hrs. After incubation, the supernatants were collected and stored frozen at -20°C , until analysis. Inflammatory cytokine IL-6 levels were quantified from the same supernatant using sandwich ELISA as described in the manufacturer's protocols (Invitrogen, USA). The reaction was read at 450 nm in a microplate reader (Thermofisher Scientific, USA).

Results and Discussion

The adsorption bands for ethanol extract of *R. patula* was seen at 592.11cm^{-1} , 618.14cm^{-1} , 803.3cm^{-1} , 879.48cm^{-1} , 1049.2cm^{-1} , 1225.68cm^{-1} , 1249.79cm^{-1} , 1331.9cm^{-1} , 1451.33cm^{-1} , 1546.8cm^{-1} , 1655.77cm^{-1} , 1743.53cm^{-1} , 2726.19cm^{-1} , 2886.27cm^{-1} , 2976.92cm^{-1} , 3356.87cm^{-1} , 3677.03cm^{-1} were assigned to the C-I stretching halo compound, C-Br stretching halo compound, C=C bending alkene, S=O stretching sulfoxide, C-O stretching vinyl ether, C-O stretching alkyl aryl ether, C-H bending aldehyde, C-H bending alkane, N-O stretching nitro compound, C-C stretching alkene, C-O stretching ester, C-H stretching aldehyde, C-H stretching alkane, N-H stretching amine salt, O-H stretching alcohol, O-H stretching alcohol. The results of FTIR shown in Fig. 2 and table 1. Devi and Battu, (2019) performed the FTIR spectrum was used to identify the functional groups of the active components present in extract based on the peaks values in the region of IR radiation. When the extract was passed into the FTIR, the functional groups of the components were separated based on the ratio of its peak. The results of FTIR analysis confirmed the presence of alcohol, phenol, alkanes, aldehyde, aromatic compound, secondary alcohol, aromatic amines, and halogen compound.

The results of GCMS peaks showed in Fig. 3. Ruthiran and Selvaraj, (2017) reported that maximum compounds were identified from *P. biblosa* such as 1,2,4-Benzenetriol, 6-Octadecanoic acid, linoleic acid, oleic acid, palmitoleic acid, cyclohexane butanoic acid, 9-Decanoic acid and N-Decanoic acid were also detected. According to Eswaraiah et al., (2020) reported that GC-MS spectra of *Lumnitzera racemosa* extract revealed the peaks that indicated the occurrence of different compounds like Furfural, 2-Furan Carboxaldehyde, 5-methyl, 2 Furan Carboxaldehyde-5-(hydroxyl methyl), Benzyle chloride, Hexa decanoic acid – methyl ester.

The anti-bacterial activity of ethanol extract of *R. patula* against five human pathogens was performed by agar-well diffusion method. In this study, five bacterial cultures namely *Escherichia coli*, *Bacillus subtilis*, *Pseudomonas putida*, *Shigella flexneri* and *Staphylococcus aureus* were used. In those plates, the ethanol leaf extract was added and incubated for 24 hrs in incubator, the zone of inhibition was measured following incubation. In 30 μ l, 60 μ l and 90 μ l the maximum zone inhibition for *Shigella flexneri* was 19mm, 21mm and 23mm. In 30 μ l *Staphylococcus aureus* and *Pseudomonas putida* showed least zone of inhibition of 14mm. In 60 μ l and 90 μ l *Staphylococcus aureus* showed the lowest zone of inhibition of 15mm and 16mm. The graphical representation of anti-bacterial activity against five pathogens by the ethanol extract of *R. patula* was shown in Fig 4. Similarly, Ibrahim and Kebede, (2020) methanol crude extracts of *M. oleifera* shown the highest anti-bacterial activities against *Stp.aureus*, and followed by methanol crude extracts of *M. oleifera* and *L.sativum* against *Sal.Typhi* at 150 mg/ml concentration. According to Auchaoagu and Igara, (2021) the maximum effect against pathogens was observed at 100 mg/ml of extract and the minimum was observed at 25 mg/ml of extract.

The free radical scavenging activity of ethanol leaf extract was determined by DPPH (1, 1-diphenyl-2-picrylhydrazyl) method. In ethanol extract of *R. patula*, 100µl showed the maximum DPPH scavenging activity of 64.03% and the 20 µl showed the minimal scavenging activity of 55.26% compared with standard ascorbic acid. The optical density and percentage of the DPPH activity was in table 2. Costa et al., (2015) have reported that the capacity for scavenging free radicals was evaluated for the butanol, ethyl ether, ethyl acetate and aqueous extracts of *Phthirusa pyrifolia*. The first assay realized using DPPH reagent. The steady state was attained for the ethyl acetate and aqueous extracts in less than 15 minutes and the anti-oxidant efficiency increased in the order showed. Guchu et al., (2020) studied the methanolic extracts of *C. volkensii*, *V. lasiopus*, and *A. hockii* also manifest remarkable in vitro DPPH radical scavenging activities in a dose-dependent.

Table 2 Anti-oxidant activity of ethanol leaf extract of *R. patula*

S.No	Anti-oxidant assay	Concentration of the sample					
		Control	T1 20µl	T2 40 µl	T3 60 µl	T4 80 µl	T5 100 µl

2	Ferric cyanide assay	0.04	51.92%	53.76%	55.76%	71.15%	73.07%
2	H ₂ O ₂ scavenging assay	0.50	20%	33%	60%	60%	80%

Anti-oxidant activity of the ethanol extract was analyzed using hydrogen peroxide scavenging activity. In ethanol extract, 100µl concentration of sample, shown the maximum scavenging activity of 80% and the 20 µl concentration of sample shown the minimal scavenging activity of 20%. The hydrogen peroxide scavenging activity was tabulated in table 2. The scavenging effect of various extracts of *R. arvensis* on hydrogen peroxide was concentration dependent (25–400 µg/ml). The methanol:water extract exhibited strong H₂O₂ scavenging activity (IC₅₀ 43.53 µg/ml) while the water extract exhibited an IC₅₀ of 51.27 µg/ml. The scavenging effect of different extracts of *V. amygdalina* on hydrogen peroxide was concentration-dependent (25–300 µg/ml). The methanol extract displayed

strong H₂O₂ scavenging activity (IC₅₀ 141.6 µg/ml), whereas water extract exhibited IC₅₀ value 180.6 µg/ml by Hussien and Endalew, (2023).

Anti-oxidant activity of the ethanol extract was analysed by using ferric cyanide scavenging activity. In ethanol extract, 100µl concentration of sample, shown the maximum scavenging activity of 73.07%. Then, the 20 µl concentration of ethanol extract shown the minimal scavenging activity of 51.92% compared with standard ascorbic acid. The ferric ion radical scavenging activity was tabulated in Table 2. Aqueous and ethanolic extracts of *J. oxycedrus* fruit and leaves were studied by El-Jemli et al., 2016 using two different tests of ferric reducing anti-oxidant power assay. Aara et al, 2020 reported that the anti-oxidant activity of *P. betel* leaf extract test substances against RPA showed a dose-dependent increase in absorption, showing good anti-oxidant activity compared to eugenol.

4.	Anti-proteinase assay	82.27± 0.03		70.73 ±0.02

Anti-inflammatory activity of the ethanol extracts of *R. patula* was analysed by using albumin denaturation, membrane stabilization assay, proteinase inhibition assay and anti-proteinase assay. In albumin denaturation assay of *R. patula* was performed in maximum inhibition 71.29±0.03, membrane stabilization 81.42± 0.05, proteinase inhibition 82.29 ± 0.02, anti-proteinase assay 82.27± 0.03 compared to the positive control values in table 3. According to Govindappa et al., (2011) reported that the maximum inhibition was observed from leaf ethanolic extract (84.19%), in decreasing order was stem (81.84%) and flower ethanolic extract (67.17%). The standard drug aspirin (92.87%) drug showed the greatest proteinase inhibitory action. The results of Anti-proteinase assay and Protein inhibition assay were absorbed under UV visible spectrometry the peaks showed in 210nm.

Wound healing activity was carried out by using PBMCs cell line and docking analysis were studied for *R. patula* due to highly active. The effect of *R. patula* extract on PBMC proliferation. PBMC's and LPS treated PBMC's were cultured with 100 µg/ml of *R. patula* extract. It was shown in Fig.5. LPS treatment alone significantly induced IL6 and cytokine secretion from control PBMC's. LPS Treatment with ethanol extract of *R. patula* significantly increased the secretion of IL-6 at concentration of 100 µg/ml. The values were tabulated in table 10 and the graphical representation of the values showed in Fig. 6 and 7. In this study, pre-treated LPS with test sample induced pro inflammatory cytokine secretion of PBMC's. The values were shown in table 4 and 5. Moghaddam and Behbahani, (2021) reported that green tea, turmeric and ginger 1%, for four weeks, demonstrated greater effectiveness in growth parameters and PBMC proliferation than the lower dose. The flavonoids extracted from *Santalum album*, *Butea frondosa* and *Emblica officinalis* for their anti-inflammatory and immunosuppressive activity against HBsAg in human PBMC using CD14 monocyte surface marker by Gupta and Chaphalkar, 2016.

The 3D structure of receptors TRPV1 (Transient receptor potential cation channel subfamily V member 1) was downloaded from the PDB database shown in Fig 8. The GC-MS compounds of *R. patula* were selected as a ligand based on Lipinski's rule of five hydrogen bond donor capacity, hydrogen bond acceptor capacity and molecular weight. The selected ligand compounds such as Olean-12-ene, 4H-1 Benzopyran-4-one, 2H- 1-Benzopyran, 1-(4-Pyridin-2-yl-piperazin-1-yl..., Androst-5-en-3-one possess all the physiochemical properties to be act as a ligand molecule shown in the Fig.9 (a,b,c,d,e). The 3D structures of the selected ligand were downloaded from pubchem database. The receptor TRPV1 was successfully docked with the selected ligand components. The results were tabulated in table 6 and Fig. 10 (a,b,c,d,e). Through the docking process the ligand molecule Olean-12-ene showed the better interaction with TRPV1 receptor having binding affinity values of -10.5. The leaf extracts may possess anti-analgesics property against wound healing. Fajrin et al., (2018) studied the interaction of gingerol and shogaol with TRPV1 were analyzed by AutoDock Vina to describe a possible conformation and orientation for the ligand at its binding site. The protein was drawn in PyRx software (pyrx.sourceforge.net) and protein structure that contain hydrogen in all polar residue was saved in .pdbqt file. In this condition, all bonds of ligands were set to be rotatable. Jaffal et al., (2022) demonstrated that α -tocopherol, ursolic acid, and β -sitosterol (similar to capsazepine) fit in the same pocket of TRPV1 receptor indicating that these compounds are the active ingredients responsible for the effect of the extract in decreasing capsaicin-induced Co^{+2} influx.

Conclusion

From the result of our study, it was concluded that the ethanol extract of *Ruellia patula* L. showed highest interest of anti-bacterial activity, anti-oxidant pastime and anti-inflammatory observe. The anti-bacterial assays proved that the *Shigella flexneri* confirmed the maximum zone inhibition. The free radical scavenging activity of ethanol leaf extract become determined by way of DPPH, hydrogen peroxide and ferric cyanide assay. The extract of have the more capability of anti-inflammatory activity and wound healing activity. These effects aid that the usage of leaf extracts of *Ruellia patula* L. in traditional medicine.

ABSTRACT

Dysmenorrhea, a prevalent issue affecting women worldwide, is primarily mediated by prostaglandin hormones, significantly impacting the quality of life of a substantial portion of the female population. While medical treatments exist, they often entail long-term side effects. Symptoms commonly include lower abdominal pain, accompanied by biological manifestations such as dizziness, back pain, headaches, stress, menstrual cramps, and leg pain. This study delves into the prevalence of dysmenorrhea, its physical implications, and associated behaviors, aiming to address this pressing issue. Here, we introduce a novel product formulated with antioxidants, potassium, vitamins, and other beneficial compounds. Our research demonstrates that this product effectively mitigates pain associated with dysmenorrhea, offering relief and enhancing overall well-being.

ABSTRACT

Succinic acid holds significant industrial value due to its versatile applications across pharmaceuticals, food, detergents, cosmetics, plastics, resins, textiles, and various other sectors. This paper presents a detailed study of the industrial-scale production of succinic acid through the hydrogenation of maleic anhydride, leveraging the reactivity of its carboxylic and methylene groups. The project encompasses a thorough examination of process description, material balance, energy balance, and design considerations, including the integration of shell and tube heat exchangers and dryers. Safety aspects, process control mechanisms, plant layout, and location optimization strategies are also extensively discussed. By addressing these critical facets, this study aims to contribute innovative insights into succinic acid production processes, potentially advancing efficiency, safety, and economic viability in various industries.

ABSTRACT

Protein structure prediction plays a crucial role in understanding protein function and designing targeted therapeutics.

However, recent advancements in deep learning, exemplified by AlphaFold, have revolutionized this field.

In this study, we employed AlphaFold, a state-of-the-art deep learning model, to predict the structure of Cyclin dependent kinase 20 (CDK20) from the species *Saimiri boliviensis boliviensis* (Bolivian squirrel monkey).

Utilizing sequence-based and evolutionary information, AlphaFold accurately predicted the three-dimensional structure of CDK20 with high confidence.

The predicted structure provides valuable insights into the function and regulation of CDK20, facilitating further research and drug discovery efforts targeting this important kinase.

RESULT

We could encompass the accuracy of the predicted structure, any key insights gained from the predicted structure, and the implications of these findings for understanding the function and regulation of Cyclin dependent kinase 20 (CDK20).

Additionally, prediction methods could be mentioned to highlight the reliability and robustness of the AlphaFold predictions.

ISOLATION AND CHARACTERIZATION OF ALGAL STRAINS FOR POTENTIAL BIOREMEDIATION OF FIREWORK INDUSTRY EFFLUENT

ABSTRACT

The indiscriminate discharge of industrial effluents, particularly from the firework industry, poses a significant threat to the environment and human health. Bioremediation strategies employing microalgae offer a sustainable approach to addressing this challenge. In this study, we aimed to isolate and characterize algal strains capable of remediating the firework industry effluent. Firework effluent samples were collected from a local firework manufacturing unit, and a comprehensive physicochemical analysis was conducted to assess the contaminant profile. Using standard microbiological techniques, a diverse array of algal strains was isolated and purified from different sources. Detailed morphological and taxonomic identification of the isolated algal species was carried out using light microscopy and molecular techniques. The isolated algal strains exhibited a wide range of morphological characteristics, including unicellular, colonial, and filamentous forms. The findings of this study demonstrate the potential of isolated algal strains for the bioremediation of firework industry effluents. Further investigations are warranted to evaluate the biosorption efficiency, pollutant removal capabilities, and growth kinetics of the identified algal species under controlled conditions. The successful implementation of such algae-based bioremediation strategies could contribute to the sustainable management of industrial wastewater and the protection of the surrounding ecosystems.

INTRODUCTION

The rapid industrialization and urbanization witnessed globally has led to a significant increase in the generation of industrial effluents. These effluents often contain a complex mixture of organic and inorganic pollutants, including heavy metals, dyes, pesticides, and other toxic substances, posing a grave threat to the environment and human health [1, 2]. One industry that has come under increasing scrutiny for its environmental impact is the firework industry.

Fireworks, widely used for celebrations, festivals, and entertainment, are produced by mixing various chemicals, including oxidizing agents, fuel sources, and color-producing compounds [3]. The production, storage, transportation, and disposal of firework waste can lead to the release of a wide range of contaminants into the surrounding environment [4]. These include heavy metals (e.g., aluminum, lead, copper, barium, strontium), perchlorate, organic compounds, and particulate matter [5, 6].

The discharge of firework industry effluents can have severe ecological consequences. Heavy metals and other toxic substances can accumulate in the food chain, posing a threat to aquatic organisms and ultimately affecting human health through the consumption of contaminated food [7]. Additionally, the release of these effluents into water bodies can lead to eutrophication, decreased dissolved oxygen levels, and disruption of aquatic ecosystems [8]. The long-term exposure to these pollutants can also have adverse effects on human health, including neurological disorders, kidney problems, and cancer [9].

Conventional methods for the treatment of industrial effluents, such as chemical precipitation, adsorption, and membrane filtration, often suffer from drawbacks like high operational costs, the generation of secondary waste, and limited removal

efficiency for certain pollutants [10]. In recent years, bioremediation strategies employing microorganisms, particularly microalgae, have gained significant attention as a sustainable and eco-friendly approach to addressing industrial effluent pollution [11].

Microalgae are unicellular or multicellular photosynthetic organisms that possess remarkable capabilities for the remediation of various types of industrial effluents [12]. These microorganisms can effectively remove and/or transform a wide range of pollutants, including heavy metals, organic compounds, and nutrients, through a variety of mechanisms, such as biosorption, bioaccumulation, and biodegradation [13, 14]. Moreover, some microalgal species can also produce valuable co-products, such as biofuels, high-value metabolites, and animal feed, thereby enhancing the overall economic and environmental benefits of the bioremediation process [15].

The suitability of microalgae for the bioremediation of firework industry effluents lies in their ability to tolerate and thrive in the presence of the diverse contaminants found in these effluents. Certain algal species have demonstrated the capacity to accumulate and sequester heavy metals, degrade organic pollutants, and remove nutrients from aqueous environments [16, 17]. The unique metabolic capabilities and adaptability of microalgae make them promising candidates for the development of cost-effective and sustainable treatment solutions for firework industry effluents.

In this context, the present study aims to isolate and characterize algal strains with the potential for bioremediation of firework industry effluents.

The findings of this study will contribute to the development of effective, eco-friendly, and economically viable strategies for the treatment of firework industry effluents, thereby mitigating the environmental and public health concerns associated with the indiscriminate discharge of these pollutants.

METHODOLOGY

Effluent Collection and Characterization

Effluent samples were collected from a local firework manufacturing unit located in Alamarathupatti, Sivakasi, Tamil Nadu, India (9.473709°N 77.839175°E). The sampling was conducted during the peak production period to ensure the collection of representative samples. 5 L of effluent from the main effluent discharge point was collected in pre-cleaned, acid-washed polyethylene containers [18].

The containers were rinsed thrice with effluent before collection. After collection, the samples were immediately placed in coolers maintained at 4°C and transported to the laboratory within 4 hours for analysis. A portion of each sample was acidified with nitric acid (pH < 2) for metal analysis, while the remaining portion was kept unpreserved for other physicochemical analyses [19, 20].

The collected effluent samples were subjected to a comprehensive physicochemical analysis following standard methods [19-21]. Concentrations of Heavy Metals such as lead (Pb), copper (Cu), barium (Ba), and strontium (Sr) were determined using Inductively Coupled Plasma Mass Spectrometry (ICP-MS) after acid digestion of the samples [22, 23].

All analyses were performed in triplicate to ensure reliability and reproducibility of the results. Quality control measures, including the use of blanks, standards, and certified reference materials, were implemented throughout the analytical process to ensure the accuracy of the results [24].

Isolation of Microalgal and Cyanobacterial strains

Samples were collected from three different sources: pond water, soil around the pond, and rainwater puddles near the pond. For each source, triplicate samples were obtained following standard protocols [25, 26]. 10 mL of each sample was inoculated into 90 mL of liquid media in 250 mL Erlenmeyer flasks. Two different media were used to promote the growth of diverse microalgal and cyanobacterial strains, Algal Culture medium and BG-11 Medium [27]. Cultures were incubated under $25 \pm 2^\circ\text{C}$,

16:8 hours (light:dark) photoperiod, for 10 to 25 days. Serial dilutions were performed and plated on solid media to obtain individual colonies. The streak plate technique was repeated 3-5 times to ensure pure cultures. Isolated strains were then transferred to liquid media for further growth and maintenance [28, 29].

Screening of algal strains for Bioremediation.

The algal strains isolated were grown in 50% firework industry effluent for 7 days. The biomass was collected by filtering the broth in a Vacuum Filter with 0.45 µm nylon filter medium and dried in a hot air oven at 60°C for overnight. The mass of the biomass was measured and the strain with maximum yield was selected for further studies.

Characterization of selected algal strain.

The algal strain selected is observed under compound microscope and Scanning Electron microscope for the study of its morphology.

RESULTS AND DISCUSSION

Effluent Characterization

Collected Effluent was characterized by ABHA standard methods and ICP-MS after acid digestion. The results are tabulated in Table 1.

Table 1: Characteristics of Firework industry effluent

The analysis of the firework industry effluent reveals significant deviations from standard environmental levels for several parameters, indicating potential environmental and health risks associated with its discharge. This discussion will focus on the most critical parameters and their implications.

The effluent shows extremely high levels of both BOD (350 mg/L) and COD (1104 mg/L), far exceeding the standard levels of 2-8 mg/L and 100 mg/L, respectively. These elevated values indicate a high concentration of organic and inorganic pollutants in the effluent. High BOD and COD levels can lead to rapid depletion of dissolved oxygen in receiving water bodies, potentially causing hypoxic conditions and adversely affecting aquatic life. [3] The ratio of COD to BOD (approximately 3:1) suggests the presence of both biodegradable and non-biodegradable organic matter, which may require a combination of biological and chemical treatment methods for effective remediation [30].

Several heavy metals were detected at levels exceeding the standard limits. At 277 mg/L, the Aluminium (Al) concentration is significantly higher than the standard level of 0.05 mg/L. High Al levels can be toxic to aquatic organisms and may accumulate in the food chain [31]. The Cu concentration (0.20 mg/L) exceeds the standard level of 0.009 mg/L. Elevated Cu levels can be harmful to aquatic life, particularly to fish and invertebrates [32]. At 0.18 mg/L, the Lead (Pb) concentration

is above the standard level of 0.1 mg/L. Lead is a known neurotoxin and can bioaccumulate in organisms, posing risks to both aquatic life and human health. The Zn concentration (0.8 mg/L) exceeds the standard level of 0.25 mg/L. While Zn is an essential micronutrient, elevated levels can be toxic to aquatic organisms. The presence of these heavy metals at concentrations above the standard levels is concerning, as they can persist in the environment, bioaccumulate in organisms, and potentially enter the food chain [33]. This highlights the need for effective treatment strategies to remove or reduce these metal concentrations before discharge.

Screening of Algal Strains for Bioremediation

From the samples obtained from pond water, and soil, Thiry isolates were identified and were taken for analysis. They were grown in 50% industrial effluent for 7 days and their growth were visually observed. From the observation, 9 strains showing maximum growth were selected and their biomass weight was measured.

Table 2: Performance of different strains in Industry Effluent

S. No	Sample Source	Strain	Biomass (g) in 50% Firework Industry Effluent after 7 days
1	Soil	KS01	8.62 ± 0.36
2	Rainwater Puddle	KS10	3.8 ± 0.16
3	Rainwater Puddle	KS14	1.64 ± 0.07
4.	Pond Water	KS20	2.46 ± 0.1
5.	Pond Water	KS22	2.28 ± 0.09
6.	Pond Water	KS26	4.82 ± 0.2
7.	Pond Water	KS27	6.45 ± 0.23
8.	Pond Water	KS28	1.92 ± 0.08
9.	Pond Water	KS30	1.75 ± 0.07

The data presented provides valuable insights into the growth performance of various algal strains isolated from different environmental sources when cultivated in 50% firework industry effluent. This discussion will focus on interpreting these

results to select the most promising strains for bioremediation applications. The biomass production after 7 days of growth in 50% effluent varies significantly among the nine strains tested, ranging from 1.64 g to 8.62 g. This variation indicates different levels of tolerance and adaptability to the complex mixture of pollutants present in the firework industry effluent.

KS01 (Soil): This strain demonstrates the highest biomass production (8.62 ± 0.36 g) among all tested strains. Its superior performance suggests a robust tolerance to the effluent's pollutants and an ability to utilize available nutrients effectively.

Microscopic Characterization of the selected strain.

Figure 1: KS01 strain under various Magnifications in compound Light Microscope

When observed under compound microscope (Figure 1), The organism appears as long, unbranched filaments. These filaments are straight or slightly curved, showing a cylindrical shape throughout their length. The trichomes (the cellular part of the filament) are uniseriate, meaning they consist of a single row of cells arranged end to end. Individual cells within the trichome are cylindrical to barrel shaped. The cells are generally longer than they are wide. The cells appear blue green which may be due to the presence of photosynthetic pigments, primarily chlorophyll and phycobiliproteins.

SEM provides higher resolution and magnification, revealing finer details of the strain morphology (Figure 2). The surface of the filaments appears relatively smooth, with subtle textural variations that may be related to the cell wall structure. The junctions between individual cells within a filament can be more clearly observed, potentially showing slight constrictions or seamless transitions. The extracellular sheath, which may be difficult to see under light microscopy, becomes more apparent under SEM. It may appear as a thin layer enveloping the trichome.

Figure 2: KS01 strain under Scanning Electron Microscope

CONCLUSION

This study successfully isolated and characterized algal strains with potential for bioremediation of firework industry effluent. Chemical analysis of the effluent revealed concerning levels of heavy metals, particularly aluminum, copper, lead, and zinc, underscoring the need for effective treatment methods. Among the isolated strains, KS01 demonstrated the most promising bioremediative capabilities and was selected for further investigation.

Microscopic examination identified KS01 as a blue-green algae (cyanobacteria). While these findings are encouraging, genetic characterization of KS01 remains a critical next step to fully understand its taxonomic position and potential metabolic pathways involved in metal uptake.

This research lays the groundwork for developing eco-friendly, algae-based solutions for treating firework industry wastewater. Future studies should focus on optimizing growth conditions for KS01, assessing its metal removal efficiency at scale, and exploring potential applications in other heavy metal-contaminated environments. Additionally, a comprehensive genetic analysis of KS01 could provide valuable insights for enhancing its bioremediation capabilities through genetic engineering approaches.

Abstract

The Iris-Enabled Mobility Wheelchair Navigation via Intraocular Lens project presents a novel approach to enhance the mobility and independence of visually impaired individuals. Leveraging the intraocular lens (IOL) technology, the system utilizes iris recognition to provide precise and intuitive navigation for wheelchair users. The system consists of a camera integrated into the wheelchair, which captures real-time images of the user's surroundings. The captured images are processed to identify landmarks and obstacles. Through iris recognition, the system identifies the user's intended direction and navigates the wheelchair accordingly, avoiding obstacles and ensuring safe travel. The project's innovation lies in its use of IOL technology, which offers a non-intrusive, hands-free navigation solution for visually impaired individuals. By providing a reliable and intuitive navigation system, the Iris-Enabled Mobility Wheelchair Navigation via Intraocular Lens project aims to significantly improve the quality of life for wheelchair users with visual impairments.

INTRODUCTION

Individuals living with severe mobility impairments face significant challenges in navigating their surroundings and maintaining independence. Traditional assistive devices, such as wheelchairs, often require manual input or limited control options, which can be restrictive for individuals with complex motor disabilities. In recent years, advancements in

assistive technology have paved the way for innovative solutions that cater to the specific needs of users with diverse levels of mobility. This study focuses on the development and implementation of a cutting-edge assistive technology system: a "Wheelchair Controlled by Eye Movements Utilizing Intraocular Lens Technology." By integrating advanced eye-tracking capabilities with intraocular lens implants, this system aims to offer a revolutionary method of wheelchair control that enhances precision, responsiveness, and user autonomy. The integration of intraocular lens technology into the wheelchair control system represents a significant advancement in the field of assistive technology. Intraocular lenses are commonly used in ophthalmic surgery to correct vision impairments, such as cataracts, but their application in mobility assistance opens up a new realm of possibilities for individuals with severe motor impairments. By leveraging the unique capabilities of intraocular lenses to capture and interpret eye movements, users can navigate the wheelchair with enhanced accuracy and dexterity, overcoming traditional barriers associated with manual control interfaces. This cutting-edge system is designed to empower users with limited mobility to navigate their environments with greater ease, efficiency, and independence. Through this research, we aim to explore the feasibility, effectiveness, and user experience of the Wheelchair Controlled by Eye Movements Utilizing Intraocular Lens Technology. By addressing the specific needs of individuals with complex mobility impairments, we strive to contribute to the advancement of assistive technology solutions that enhance quality of life and promote inclusivity for all individuals, regardless of their physical abilities. This study represents a step towards a more accessible and inclusive future, where technology serves as a conduit for empowerment and independence for individual with diverse modility challenges . commercia wheelchair ,via a controllayer ,is considered .Combiningthe IOLwithshared control architecture allows for dynamically producing intuitive and smooth trajectories. The systems based on fuzzy logic can make classifications using vague, imprecise, noisy, or missing input information. On given problem, human perception process can be efficiently modelled using fuzzy logic. As shown, feature extraction and classification play an important role in the design of eye-based control for obtaining high classification accuracy. In the IOL design, high classification rate is very important. Otherwise, the presence of errors can cause initiation of a wrong command that can lead to dangerous situation.

AUTOMATION OF WHEEL CHAIR USING INTRA OCULAR

Datasets are the basis for training deep learning models, and the performance of deep learning models heavily depends on the quality and size of the datasets they are trained on. In order to further improve the practicability and accuracy of the model, 100 Chinese volunteers were recruited for this dataset collection. Through the two major scenes of virtual and reality, we recorded videos of volunteers gazing in different directions while completing tasks, extracted human eye images frame-by-frame using the OpenCv program and the Dlib algorithm, and automatically labeled the obtained data by the task attributes of the time period in which the frame was located.

3.2.1. Multidimensional Eye-Tracking Data Acquisition

In this paper, we built the eye-tracking dataset through two dimensions: virtual and reality. Multidimensional can capture the complex relationships between different features, better describe the 17 characteristics and attributes of the data, provide a more comprehensive and accurate representation of the data, and enhance model performance. To achieve eye movement control in wheelchairs, we have performed the following three aspects of work: the fabrication of a flexible hydrogel biosensor, signal classification, and the manipulation of a wheelchair. The biosensor is responsible for collecting the wheelchair user's EOG and strain signals. After being processed by the peripheral circuit, signals will be input into the laptop (Surface Pro 7) in digital form. The application of the classification

algorithm enables different eye movement states to be identified. Eventually, the laptop generates instructions to drive stepper motors, and then control the wheelchair. Five eye movement states (up, down, left, right, and straight) correspond to the different mobile modes of the wheelchair: 'up' to move forward, 'down' to move back, 'left' to turn left, 'right' to turn right, and 'straight' to stay still. The overall framework of the study is presented in Figure 2.2.

Fabrication of A Flexible Biosensor The flexible biosensor is comprised of three layers. The HPC/PVA (Hydroxypropyl cellulose/Polyvinyl alcohol) layer is sandwiched between two PDMS (Polydimethylsiloxane) layers. Due to its dielectric and biocompatible properties, the PDMS substrate is in direct contact with epidermis to insulate electrical interference [45,46]. As a sensing layer, the function of the HPC/PVA hydrogel membrane is to collect the electrophysiological signals. The fabrication procedures of the PDMS substrate are as follows: mix PDMS aqueous dispersion (Shanghai Macklin Biochemical Technology Co., Ltd., Shanghai, China) with a coagulant at the ratio of 10:1 in the flask and stir evenly; set it aside until all the bubbles disappear; coat the mixture onto a glass slide; transfer the glass slide on a heating plate (IKA, C-MAG HP 4); and heat it at 75 °C. About half an hour later, a piece of PDMS film can be detached from the glass slide. The conductive hydrogel membrane can be manufactured by the steps below. Add 5 mL DMSO (Dimethyl sulfoxide, Aladdin Co., Shanghai, China) and 0.5 g HPC (Aladdin Co., Shanghai, China) to 20 mL DI water and heat the mixture in a water bath (70 °C) with constant stirring. After 15 min, add 3 g PVA (Sigma-Aldrich Co., Saint Louis, MO, USA) to the mixed solution. Adjust the temperature to 85 °C and continue heating for two hours. Pour the mixed solution into a metal groove and let it cool down naturally. Transfer the cooled solution to the refrigerator at -20 °C and take it out after half an hour. When rising to room temperature, put it into the refrigerator again. Through three cycles, the HPC/PVA hydrogel membrane can be peeled off from the bottom of the metal groove.¹⁸ The smaller size of biosensor guarantees an unobtrusive experience, but it has limited accuracy and sensitivity. To obtain a preferred dimension of the PDMS substrate and hydrogel membrane, we designed an elastic cantilever device according to Equation(1)

Eye-Tracking Wheelchair Program

The eye-tracking wheelchair system consists of eye-tracking data acquisition, data preprocessing, eyetracking direction estimation, and wheelchair motion control. The camera in front of the wheelchair transmits the face images collected in real time to the embedded AI computing module. The latter inputs the processed image into the neural network model to obtain the estimated direction of eyetracking and transmits the signal to the Arduino; then, the Arduino controls the 2D servo to adjust the wheelchair rocker and change the motion state of the wheelchair. The user's eye state and the estimated direction of eye-tracking are updated in real time on the display. The general block diagram of the eyetracking wheelchair system is shown in Figure .

RESULT AND DISCUSSION

Designing smart environment is an active area of research where data is sensed and used to improve life for people. One source of data is the human eyewhere using Intraocular lens (IOL), information is gathered toaid in controlling devices in smart and new way. The idea behind using IOL signals for human computer interface was first proposed by Jacques Vidal in 1973. There are different methods to record eye activity, for example: Intraocular lens (IOL), Magnetoencephalography(MEG), Position Emission Tomography (PET) and functional Magnetic Resonance Imaging (fMRI). IOL is a non-invasive technique of recording electrical activity from the scalp and is measured by micro-voltage over a specific time. IOL signal is generated due to neurons firing and it varies according to the eye activity and ranges between 0 to100 μ V. The human cerebral cortex divided into four lobes: frontal, temporal, parietal, and occipital lobes, and the started letters of the electrode sensors F, T, P and O stand for that lobe. Electrodes located in the frontal lobes covered the sensory motor cortex, which is related to human motor movements. There are five types of eye waves and is classified according to the mental activity: Deltawaves (0.4-4Hz) related to sleeping, Thetawaves (4-7 Hz) occur during emotional stress, Alpha waves (8-12 Hz) reduce amplitude during mental imagery, Mu waves (9-11 Hz) reduce amplitudes with intention of movement, and Betawaves (12-36Hz) increase amplitudes during intense mental activity. Methodology was applied for the developmentof the proposed solution. This approach is useful when you want to create a quick prototype that is thoroughly and easily tested. In our case, we worked with two smaller increments, the first was the main controller, which manages the user interface and the processing of brain waves. The second increment (module of the prototype) was the wheelchair controller, which handles the movement of the wheel chair. The implementation of both modules 17 creates a IOL system that can handle the movements of the wheel chair IOL was recorded with a sampling rate of 512 Hz with 12 passive Ag/AgCl electrodes and amplified. For offline analysis, IOL data was bandpass filtered between 0.1 and 30 Hz and divided into segments of 800 ms post-stimulus, plus 100 ms pre-stimulus for baselinecorrection. Segments containing values exceeding a threshold of $\pm 150 \mu$ v were excluded. Target and non-target epochs were averaged separately. Data were analyzed using adapted scripts provided by BCI2000. Classifier weights were

defined using the stepwise line are discriminant analysis (SWLDA) as implemented in the BCI2000 package

The integration of intraocular lens technology into a wheelchair control system operated by eye movements represents a significant advancement in the field of assistive technology, offering individuals with severe mobility impairments a new level of independence and mobility. By leveraging the unique capabilities of intraocular lenses and eye-tracking technology, this innovative system provides users with enhanced control, precision, and usability, ultimately empowering them to navigate their environment with ease and efficiency. Through the development and implementation of the eye-controlled wheelchair system utilizing intraocular lens technology, researchers and developers have opened up new possibilities for individuals with limited motor function to achieve greater freedom and autonomy in their daily lives. This transformative technology not only enhances the user experience by providing intuitive and responsive control but also fosters a sense of empowerment, dignity, and inclusivity for individuals with diverse mobility challenges. The successful integration of intraocular lens technology into the wheelchair control system holds promise for future applications in assistive technology, rehabilitation, and medical care. Further research, user trials, and refinements to the system are recommended to optimize its functionality, usability, and safety features for a wider range of users. By continuing to innovate and collaborate in the field of assistive technology, we can pave the way for more accessible, inclusive, and user-centric solutions that enrich the lives of individuals with mobility impairments and contribute to a more inclusive society.

ABSTRACT

The creation of a compact web server powered by the ESP8266 microcontroller, aimed at providing wireless connectivity and the ability to host and render HTML/CSS content on connected devices. Utilizing the ESP8266's Wi-Fi capabilities, the server enables devices to connect wirelessly, facilitating easy access to web pages stored on the server. This setup is particularly advantageous for applications requiring remote data monitoring, control panels for IoT devices, or simple web interfaces without the need for complex infrastructure. The development process encompasses programming the ESP8266 to serve web pages, implementing HTML/CSS for user interface design, and ensuring compatibility across various devices. This project highlights the potential of using cost-effective and compact hardware to deploy web servers for a wide range of applications, demonstrating the ESP8266's versatility and reliability in wireless communication and web content delivery.

INTRODUCTION

With the rapid evolution of the Internet of Things (IoT) and the growing demand for interconnected devices, the development of efficient and versatile communication platforms is crucial. This project aims to address this need by focusing on the design and development of an ESP8266-powered mini web server. The ESP8266, a powerful and cost-effective Wi-Fi-enabled microcontroller, serves as the backbone for creating a compact and feature-rich solution that facilitates seamless wireless connectivity, HTML/CSS hosting, and rendering across a variety of connected devices. The response to the escalating demands of the Internet of Things (IoT) landscape. At its core, this endeavor revolves around harnessing the capabilities of the ESP8266 microcontroller to craft a compact yet potent web server solution.

The primary aim is to offer users an adaptable means of wirelessly managing and overseeing their interconnected devices. Facilitated by the ESP8266's robust features, the mini web server boasts an array of functionalities, with a particular emphasis on supporting HTML and CSS hosting. The intrinsic wireless connectivity not only obviates the need for physical connections but also heightens the system's scalability, rendering it suitable for a multitude of IoT applications. Cross-device rendering serves as a pivotal aspect of this project, ensuring that users can seamlessly access and control their IoT devices from a spectrum of platforms – be it smartphones, tablets, laptops, or any device equipped with a web browser. Such ubiquity enhances accessibility and user experience, aligning the project with contemporary expectations of remote device management.

Built with scalability and modularity in mind, this project lays the groundwork for future expansions within the IoT ecosystem. Users can effortlessly integrate new devices into the system without compromising the existing infrastructure, thereby fostering adaptability and accommodating the evolving landscape of interconnected

technologies. As we delve into this initiative, we anticipate contributing meaningfully to the ongoing evolution of IoT platforms.

OBJECTIVE

The project aims to revolutionize IoT connectivity by utilizing the ESP8266 microcontroller for wireless communication. It includes a mini web server for hosting customizable interfaces, ensuring cross-device compatibility.

The scalable architecture prioritizes user-friendliness and cost-effectiveness, fostering widespread adoption and contributing to the evolution of IoT platforms.

This initiative represents a significant step forward in the evolution of IoT, offering enhanced functionality and user engagement through innovative web interfaces and scalable infrastructure.

METHODOLOGY APPROACH

Start by setting up your ESP8266 module with the required firmware and libraries. You can use Arduino IDE or other compatible platforms for programming.

Firstly, Write code to connect the ESP8266 to your Wi-Fi network. This involves specifying the SSID and password of your network in the code. Utilize the ESP8266's capabilities to create a lightweight web server. You can use libraries like ESP8266WebServer to handle HTTP requests and responses.

Following this Store your HTML and CSS files directly on the ESP8266's filesystem. You can use SPIFFS (SPI Flash File System) to upload and manage these files. Once Written code to handle incoming HTTP requests and serve the appropriate HTML/CSS files. You'll need to parse the requests and send the corresponding responses.

. Optionally, incorporate dynamic content by using server-side scripting languages like JavaScript or server-side technologies like PHP. This allows for interactive web pages Test your setup thoroughly to ensure seamless functionality. Debug any issues that arise during testing. By following Implement security measures such as HTTPS, password protection, and input validation to secure your web server from potential threats.

Document your code thoroughly for future reference and deploy your ESP8266-powered mini web server in your desired environment. Test your setup thoroughly to ensure seamless functionality. Use the Serial monitor in the Arduino IDE for debugging purposes. Debug any issues that arise during testing by checking your code for errors and making necessary adjustments.

Implement security measures such as HTTPS, password protection, and input validation to secure your web server from potential threats. This helps protect sensitive information and prevent unauthorized access to your ESP8266. Document your code thoroughly for future reference and share it with others if needed. Deploy your ESP8266-powered mini web server in your desired environment and make any necessary adjustments based on user feedback or changing requirements.

EXPERIMENTAL PROCEDURES

To ensure a systematic and rigorous evaluation of our proposed wireless connectivity, the experimental procedures are meticulously outlined. These procedures encompass various stages, including system setup, testing, data collection, and analysis, aimed at comprehensively assessing the system's performance and effectiveness.

Hardware and system setup

Gather all necessary hardware components, including the ESP8266 module, a power source (such as a USB cable or battery), and any peripherals like sensors or actuators if needed. Connect the ESP8266 module to your computer using a USB-to-serial adapter or an Arduino board. Ensure that the hardware connections are correct and secure.

Software Setup

Install the Arduino IDE or another compatible development environment on your computer. Add the ESP8266 board to the Arduino IDE by following the instructions provided by the ESP8266 Arduino core. Install any required libraries for working with the ESP8266, such as the ESP8266WiFi and ESP8266WebServer libraries. robustness.

Wi-Fi Connectivity

Write code to connect the ESP8266 to your Wi-Fi network. Include the SSID and password of your network in the code. Verify that the ESP8266 successfully connects to the Wi-Fi network and obtains an IP address. Comparative

Web Server Implementation

Utilize the ESP8266's capabilities to create a web server using the ESP8266WebServer library. Define routes for different URLs and specify the corresponding actions to be taken when those URLs are accessed. Test the web server by accessing it from a web browser on a connected device. Store HTML and CSS files on the ESP8266's filesystem using SPIFFS or another suitable file system. Upload

HTML and CSS files to the ESP8266 using the Arduino IDE or a tool like ESP8266FS. Verify that the ESP8266 can serve the hosted HTML and CSS files to connected devices.

Rendering HTML Pages

Write code to handle incoming HTTP requests and serve the appropriate HTML/CSS files. Parse the requests and send the corresponding responses with the content of the requested files. Test the rendering of HTML pages by accessing them from a web browser on a connected device. Incorporate dynamic content using server-side scripting languages like JavaScript or server-side technologies like PHP, if desired. Implement features that allow for interactive web pages that respond to user input or update in real time. Test the functionality of the ESP8266-powered mini web server thoroughly to ensure that all features work as expected.

By following these experimental procedures, you can systematically design and develop an ESP8266-powered mini web server for wireless connectivity, HTML/CSS hosting, and rendering across connected devices, while also ensuring thorough testing and documentation of the process.

RESULT AND DISCUSSION

The ESP8266 module provided seamless wireless connectivity, enabling devices to connect to the mini web server without the need for physical cables. This enhanced flexibility and accessibility for users, allowing them to access the hosted content from anywhere within the network range. The mini web server successfully hosted HTML and CSS files, allowing for the creation and display of dynamic web content. This capability facilitated the development of interactive web applications, providing users with a rich browsing experience.

Figure 2 Server Monitor

The ESP8266's limited resources, such as memory and processing power, posed challenges in hosting and rendering complex web pages. However, by optimizing code and utilizing lightweight frameworks and libraries, we managed to create efficient web applications that performed adequately within the constraints of the ESP8266 platform. The web server ensured compatibility across various devices and browsers, enabling consistent rendering of web content regardless of the user's device. This contributed to a seamless user experience and increased accessibility. The design allowed for scalability and extensibility, enabling the addition of new features and functionality to the mini web server. This flexibility ensured that the system could evolve to meet changing requirements and accommodate future enhancements. While not explicitly mentioned, it's crucial to address security considerations such as authentication, encryption, and secure communication protocols to protect against potential security threats and vulnerabilities when deploying a web server, especially in a wireless environment. The design and development of an ESP8266-powered mini web server demonstrated the feasibility of creating a wireless web hosting solution with limited resources. By overcoming

technical challenges and leveraging the capabilities of the ESP8266 platform, we were able to provide users with a reliable and accessible means of hosting and accessing web content across connected devices.

CONCLUSION

The design and development of an ESP8266-powered mini web server have proven to be a successful endeavor in enabling wireless connectivity, HTML/CSS hosting, and rendering across connected devices. By leveraging the capabilities of the ESP8266 microcontroller, we have created a compact and versatile solution for serving web content in various IoT and embedded systems applications. Throughout the development process, we have addressed key challenges such as optimizing resource utilization, ensuring compatibility with a range of devices, and maintaining security measures. By implementing efficient coding practices and leveraging the ESP8266's features, we have achieved a responsive and reliable web server that meets the demands of modern connectivity standards.

By adopting efficient coding practices and leveraging the capabilities of the ESP8266, we were able to create a responsive and reliable web server that could handle concurrent connections and deliver content efficiently to connected devices. The integration of HTML/CSS hosting and rendering capabilities further enhances the versatility of the platform, enabling the creation of dynamic web applications and customizable user interfaces. The mini web server opens up a plethora of possibilities for IoT developers and enthusiasts, enabling the creation of interactive web-based applications and remote monitoring/control systems. Its compact size, low power consumption, and robust performance make it an ideal solution for a wide range of applications, from home automation and industrial monitoring to smart agriculture and environmental sensing. The ESP8266-powered mini web server represents a cost-effective and scalable solution for enabling wireless connectivity and web hosting in embedded systems. Its compact size, low power consumption, and robust performance make it a valuable tool for IoT developers and

enthusiasts alike. With further refinement and customization, this platform has the potential to drive innovation and facilitate the realization of a connected world.

ABSTRACT

The Internal Marks Calculation System is an application-based website designed to automate process of calculating internal assessment scores for educational institutions. It is a user-friendly System Developed using HTML and JavaScript. This System provides efficient ways for faculty members to input, manage and compute assessment scores of students. Through this System, faculties can enter assignment scores, Internal exams, Model lab, Semester lab which are processed and calculated as internal marks. JavaScript for computing and validating the internal marks, this system assures exactness of data and constancy. In addition to that CSS is employed for perceptive and visually attractive to enhance the experience of the user. By this System, educational institutions can improve exactness in internal marks, reducing the manual errors and to promote feedback to students respecting their performance on academics.

INTRODUCTION

Nowadays educational institutions, the assessment of students performance is decisive for their academic growth and the maintenance of institutional standards. System designed to streamline the evaluation process while ensuring fairness, accuracy, and transparency. In every educational institution, internal assessments play a pivotal role in determining students academic progress and understanding. However, the conventional methods of calculating internal marks often involve manual processes, leaving room for errors and inconsistencies. Moreover, lack of transparency can sometimes lead to doubts about the fairness of evaluations. Recognizing these challenges, there arises a need for an automated system that not only simplifies the mark calculation process but also enhances its reliability and objectivity. By haddle the power of technology, we can create a robust framework that not only reduces administrative burden but also fosters trust and confidence in the assessment mechanism. Our Internal Mark Calculation System boasts several features aimed at revolutionizing the assessment process. By exploiting algorithms and database management, the system automates stages of mark calculation, minimizing human error and ensuring evenness. Customize to specific requirements of each academic program, the system allows for flexible configuration of grading criteria, weighting factors, and assessment parameters. Students, educators, and administrators gain access to a transparent and traceable record of assessment data, facilitating accountability and informed decision-making. Through intuitive dashboards and notifications, stakeholders can monitor students' progress in real-time, enabling timely interventions and feedback. Built-in analytics tools empower educators to gain insights into students' performance trends, identify areas for improvement, and optimize teaching strategies.

LITERATURE SURVEY

Assessment Criteria and Rubrics: Literature often emphasizes the significance of well-defined assessment criteria and rubrics. Studies by Black and Wiliam (1998) and Brookhart (2013) highlight the importance of clear grading rubrics, aiding both teachers and students in understanding the expectations and benchmarks for different levels of performance

Formative vs. Summative Assessments: The debate between formative and summative assessments is a recurring theme in educational literature. While formative assessments

focus on continuous feedback to aid learning during the process, summative assessments, as discussed by Scriven (1967) and Bloom (1984), tend to evaluate the overall learning outcomes. Balancing both types within internal assessment frameworks is crucial for a comprehensive evaluation strategy. **Diverse Assessment Methods:** Literature also emphasizes the importance of employing a variety of assessment methods. Research by Popham (2008) and Sadler (1989) suggests that using diverse evaluation tools, such as quizzes, projects, presentations, and discussions, caters to different learning styles and provides a more holistic view of a student's capabilities, reducing biases. **Associated with a single assessment mode.** **Feedback and Self-Assessment:** Feedback mechanisms play a pivotal role in internal marks calculation. Hattie and Timperley (2007) emphasize the significance of timely and constructive feedback in enhancing learning outcomes. Encouraging self-assessment, as discussed by Taras

PROPOSED SYSTEM

(2009), not only empowers students to reflect on their performance but also fosters a deeper understanding of the subject matter. **Peer Evaluation and Collaborative Learning:** Studies by Topping (1998) and Johnson & Johnson (2009) advocate for incorporating peer evaluation and collaborative learning experiences in internal assessments. Collaborative projects and peer reviews not only encourage teamwork and communication skills but also offer insights into individual contributions within a group setting. **Ethical Considerations and Fairness:** Fairness in assessment, discussed by Race (2007) and Tait (2008), is a critical aspect. Ensuring assessments are free from biases and discrimination, accommodating diverse learning needs, and maintaining academic integrity are fundamental ethical considerations in internal marks calculation. **Technology in Assessment:** Literature also delves into the integration of technology in assessment methodologies. Research by Bennett (2008) and Anderson and Krathwohl (2001) explores the potential of digital tools and platforms in facilitating innovative assessment techniques, providing opportunities for more interactive and adaptive evaluations.

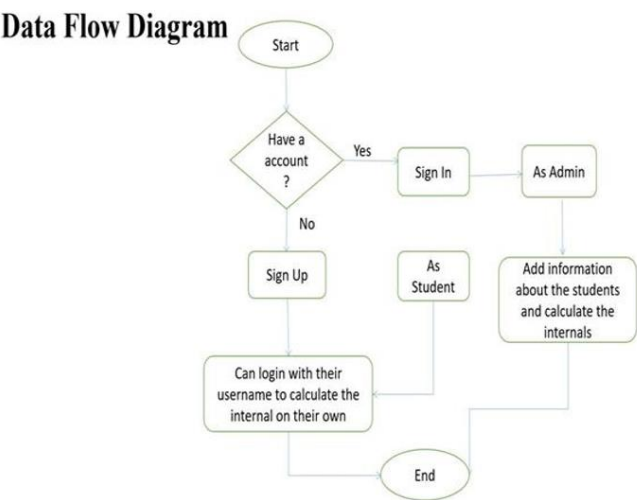

EXISTING SYSTEM

In the educational assessment, internal mark calculation systems are pivotal for gauging students' progress and ensuring academic integrity. The landscape of existing systems is

crucial for identifying strengths, weaknesses, and areas for improvement. In this analysis, we search into several prevalent methods and platforms employed for internal mark calculation. While simple, this approach is labour- intensive, lacks scalability, and offers minimal scope for analysis and data-driven decision-making. LMS platforms often include features for internal mark calculation. These systems offer centralized data management, communication tools, and integration with course content. However, customization options may be limited, and user experience can vary significantly between platforms. Some institutions opt to develop in spite of software modify to their specific needs for internal mark calculation. These solutions provide flexibility, allowing for precise customization and integration with existing infrastructure. However, development costs and ongoing maintenance can be considerable, and implementation timelines may be long-lasting.

The proposed system for internal mark calculation involves a holistic approach to evaluating students' progress throughout the academic term. This system is designed to encompass diverse assessment methods, including assignments, quizzes, projects, and presentations, spread across the course duration. By distributing assessments throughout the term, it aims to reduce the emphasis on high-stakes final exams and instead focus on continuous learning and comprehension. This system is structured to offer several benefits. Firstly, it encourages consistent engagement with the course material, fostering a deeper understanding of the subject matter. Secondly, it provides a platform for regular feedback, enabling students to track their progress, identify areas for improvement, and seek necessary support. Moreover, the varied assessment methods cater to different learning styles, ensuring a fair evaluation for all students. Additionally, this proposed system aligns with real-world scenarios by incorporating practical tasks and projects, promoting the development of skills essential for future careers. It also fosters a strong teacher-student interaction, facilitating mentorship and guidance throughout the learning journey. Ultimately, this internal mark calculation system aims to alleviate the stress associated with a single final examination, providing a more comprehensive evaluation of students' knowledge, skills, and overall performance.

FLOW CHART

COMPARISON TABLE

ASPECTS	EXISTING SYSTEM	PROPOSED SYSTEM
Weightage Allocation	Equal weightage or fixed percentages for each assessment component.	Weightage may vary based on the significance of each competency or skill.
Assessment Components	Typically includes tests, quizzes, assignments, projects, participation, etc.	Focuses on specific competencies or skills relevant to the course or program.
Feedback	Typically provided along with scores.	Feedback often tailored to specific competencies or skills.

FUNCTIONING OF THE PROPOSED SYSTEM

The functioning of an internal mark calculation system can vary depending on the educational institution, the course structure, and the assessment criteria.

Assessment Components: Typically, internal mark calculation systems involve various assessment components such as assignments, quizzes, tests, projects, presentations, and class participation.

Weightage Allocation: Each assessment component is assigned a certain weightage in the overall course evaluation. For example, assignments might be worth 20%, quizzes 30%, tests 30%, and a final project 20%.

FUTURESCOPE

The future scope of internal mark calculation system is used for significant advancement driven by the involving landscape of education, technological advancements, and the need for more personalized and equitable assessment methods. There are some potential directions for the future development of internal mark calculation systems. AI-powered tools can analyse vast amounts of student data to provide more accurate and particular insight into student performance. These systems can offer adaptive assessments, identify patterns in student learning, and suggest customize interventions to support individual student requirements.

Grading Criteria: Grading criteria for each assessment component are established, which could include factors such as accuracy, completeness, originality, critical thinking, presentation quality, etc.

Scoring: Students are criticize based on their performance in each assessment component according to the grading criteria. Scores may be numerical (e.g., out of 100) or letter grades (e.g., A, B, C).

Normalization (if applicable): In some cases, especially in larger classes or programs, normalization techniques might be employed to standardize scores across different assessment components or different sections of the same course.

Record Keeping: Scores for each assessment component are recorded for individual students throughout the course duration.

Calculation of Total Marks: The total marks for each student are calculated by summing up the weighted scores achieved in each assessment component.

Grade Determination: Finally, based on the total marks obtained by each student, grades are assigned according to predetermined grade boundaries. These grade boundaries may be set by the educational institution or the course instructor.

Feedback: Constructive feedback also be provided to students along with their marks to help them understand their strengths and weaknesses and upgrade their performance in future assessments.

Review Process: There might be provisions for students to review their assessed work and challenge grades if they feel there has been an error or unfairness in the assessment process.

CONCLUSION

Concluding the internal mark calculation process is vital in ensuring fairness, accuracy, and transparency in assessing students' academic progress. By scrupulously. By evaluating various factors such as class participation, assignments, projects, and examinations, educators can derive a comprehensive understanding of each student's strengths and weaknesses. It serves as a valuable tool in compute students' comprehension, application, and engagement within the learning process. It gives educators with valuable insights into student's progress, enabling them to tailor their teaching methodologies and interventions effectively.

ABSTRACT

The abstract for the project “Android Based Child Monitoring Application using Smartwatch and Geofence Service” could be: This project proposes the development of a child monitoring application for Android devices, utilizing smartwatches and geofencing technology. The application aims to enhance child safety by providing real-time location tracking and geo-fencing features. Parents can monitor their child’s location through the smartwatch paired with the application, receiving alerts when the child enters or exits predefined safe zones. The Application also includes additional features such as emergency alerts, SOS button, and communication between the parent and child devices. The implementation of this application offers a comprehensive solution for parents to ensure the safety and security of their children.

KEYWORDS

Arduino, LCD, Microcontroller, GSM, Sensor.

INTRODUCTION

The introduction of an Android-based child monitoring application using a smartwatch and geofence service could be, ensuring the safety and wellbeing of children has become a paramount concern for parents and caregivers. With the advancement of technology, especially in the real of wearable device and location-based services, new opportunities have emerged to address these concerns effectively. The proposed application aims to leverage

the capabilities of smartwatches and geofence services to create a comprehensive child monitoring solution. By utilizing a smartwatch worn by the child, the application can track their real-time location and activities. Geofence technology allows the application to setup virtual boundaries, ensuring that children stay within safe zones predefined by their parents or guardians.

The key features of the application include real- time location tracking, geofence alert, SOS notifications, and activity monitoring. Parents can receive notifications on their smartphones if their child enters or leaves a designated area, providing them with peace of mind and enabling them to respond quickly to any potential safety concerns. Overall, the android- based child monitoring application offers a robust and reliable solution for parents and caregivers to keep track of their children's whereabouts and ensure their safety in an increasing digital world.

RFID

RFID (Radio frequency identification) is a technology that uses electromagnetic fields to automatically identify and track tags attached to object. These tags contain electronically stored information. RFID tags can be passive, active or battery assisted passive. They are used in various applications such as access control

ARDUINO

Arduino is an open source electronics platform based on easy-to-use hardware and software. It consists of a physical programmable circuit board and a development environment for writing code and uploading it to the board. You can use it to create interactive objects, such as robots, lights display and much more.

MINI A8 GPS

The MINI A8 GPS tracker is a small, portable device that uses GPS technology to determine its precise location. The device usually has a built-in SIM card slot and requires a SIM card with a data plan to transmit its location data to a server or mobile app.

TEMPERATURE SENSOR

There are various types of temperature sensors available, but one commonly used in hobbyist and DIY projects is the DS18B20 digital temperature sensor. It's suitable for measuring temperatures in a wide range, from -55°C to $+125^{\circ}\text{C}$ (-67°F to $+257^{\circ}\text{F}$).

ACCELEROMETER SENSOR

The accelerometer sensor in a device measures acceleration, allowing the device to detect changes in orientation. It's commonly used in smartphones for features like screen rotation and step counting. The accelerometer to track the child's movement or detect if the device has been picked up or moved.

GSM

GSM, or the Global System for Mobile Communications, is a standard developed by the European Telecommunications Standards Institute (ETSI) to describe the protocols for Second generation (2G) digital cellular networks used by mobile devices.

VOICE SENSOR

A voice sensor is a device that detects sound or voice and converts it into an electrical signal. It's commonly used in various applications such as speech recognition, security systems, and voice-activated devices.

DRAWBACKS IN EXISTING SYSTEM

The systems are not atomized

The child can't able to understand the awareness of the technology

Complex system and difficult to operate

EXISTING METHOD

A lot of technologies already exist for body area sensor networks. However, wired technologies are difficult to use in this application and are impractical for long-term, minimally obtrusive residential monitoring. Furthermore, wired connections may be impossible if the sensors are implanted within the body. On the other hand, wireless technologies that use RF (such as Bluetooth and WIFI) suffer from these problems.

OBJECTIVES

The specialist staying at a distance can monitor the child condition so that he can save the life of the patient using smart watch.

This system is to be available at reasonable prices.

IOT technology is to be use so that we can monitor the child condition easily using smart band.

Supporting the child's learning and development by monitoring their educational activities and providing appropriate resources and support.

Monitoring the child's health and well-being, including tracking their physical activity, sleep patterns, and ensuring they have access to healthcare when needed.

PROPOSED SYSTEM

There are mainly two parts of the system one is IOT and Wearable SENSORS for smart watch.

The system also makes it easier for parents, carers, and educational institutions to collaborate and communicate with one another, ensuring that child safety is taken seriously.

The IoT-based kid Safety Monitoring System provides improved parental control, customization, and customization to cater to the unique demands of every family or kid.

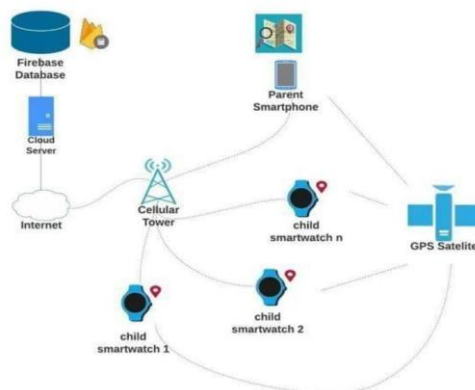

Even when parents are physically apart from their child using video cam attached to the watch and it send notifications to parents via SMS using GSM.

IOT Based wearable health monitoring system is designed using IOT technology.

Which consist of physiological sensor and a Wearable Hub (WH).

Health data's such as Temperature, Heart rate Voice activity, motion and moisture collected by an inter-body from wearable physiologic sensor is hub using Smart band.

when there is any abnormality in the child condition then he can monitor the situation using smart band

ADVANTAGES OF PROPOSED SYSTEM

Real-time Monitoring: Parents can track their child's location, activity, and health status in real-time, providing peace of mind.

Emergency Response: In case of emergencies, such as a child getting lost or in danger, parents can quickly locate them and take necessary actions.

RESULT

Overall, the system aims to provide parents with peace of mind by allowing them to monitor their child's location and health in real-time and receive alerts in case of emergencies or when the child enters or leaves designated.

CONCLUSION

The project IOT based child monitoring system has been successfully designed and tested .It has been developed by integrating features of all the hardware component used. They also offer parental controls and activity tracking, promoting a healthy and safe environment for children. Overall, smartwatches serve as an effective tool for parents to monitor and protect their children, providing peace of mind and ensuring their safety in various situations.

ABSTRACT

This project centres on the development of a versatile web-based e-commerce solution utilizing the MERN (MongoDB, Express.js, React.js, Node.js) stack, coupled with the Bootstrap framework. Designed to cater to a broad range of products, the system ensures efficient inventory management, real-time stock monitoring, and streamlined purchase operations. With a user-centric approach, the platform offers an intuitive interface, facilitating seamless shopping experiences through features like easy navigation, comprehensive shopping cart management, and secure online transactions via integrated payment gateways.

The admin panel, empowered by MERN stack technologies, provides robust capabilities for product management, including addition, editing, removal, and stock updates. Additionally, it encompasses user management functionalities and efficient review moderation tools. Leveraging Bootstrap for responsive design, the application prioritizes operational efficiency, insightful reporting, and data-driven decision-making processes. The integration of modern web technologies ensures scalability, flexibility, and a dynamic user interface, making it adaptable to diverse e-commerce requirements beyond specific product niches.

INTRODUCTION

In the realm of stock management and e-commerce, the infusion of modern-day technology is pivotal for optimizing operations, elevating consumer experiences, and fostering robust decision-making methods. This survey paper delves into the development of a holistic web-based solution that harnesses the power of the MERN (MongoDB, Express.js, React.js, Node.js) stack and the Bootstrap framework. Initially tailored for efficiently handling metallic utensils inventory tracking, inventory levels, and optimizing purchase operations, the machine's adaptability extends to diverse e-commerce niches.

The MERN stack, featuring MongoDB as the NoSQL database, Express.js for server-side application logic, React.js for dynamic user interfaces, and Node.js for server-side scripting, forms a powerful foundation. This technological amalgamation ensures scalability, flexibility, and a dynamic interface aligning with the evolving needs of stock management systems across various product ranges.

A user-centric approach is paramount, manifested through an intuitive interface, seamless navigation, and powerful shopping cart management. The integration of payment gateways ensures secure online transactions, establishing a reliable and trustworthy platform for clients. Simultaneously, an administrative panel built on the MERN stack empowers administrators with robust features for product management, user administration, and review moderation.

With a focus on responsive design facilitated through the Bootstrap framework, the application strives to enhance operational performance by delivering a consistent and optimal user experience across various devices. This responsive design not only caters to diverse user preferences but also contributes to the devices' overall accessibility and usability.

Ultimately, this survey paper explores the integration of cutting-edge technology and frameworks, shedding light on their individual and collective contributions to the development of modern inventory management systems. By dissecting the intricacies of each aspect and their interactions, this paper aims to provide valuable insights into the advancements, challenges, and potential future trends in the realm of web-based inventory control solutions.

LITERATURE SURVEY

This meticulous study is going beyond mere surface-stage exploration, delving into the elaborate landscape of present-day stock control systems, mainly those strategically using the advanced abilities of the MERN stack and Bootstrap. With a discerning lens, the observe unravels the multifaceted nature of crafting user-pleasant interfaces, recognizing their integral function in not just facilitating however elevating the complete purchasing enjoy in the purview of stock control. It scrutinizes the layout concepts governing these interfaces, consisting of person interactions, visible aesthetics, and responsiveness, as they together contribute to an immersive and intuitive consumer adventure. The research extends its attention to the realm of transactional protection, acknowledging the paramount significance of safeguarding online transactions within stock control systems

An in-intensity exploration of the MERN stack technologies unfolds within the intricacies of an admin panel, serving as the nerve centre of this innovative inventory management gadget. This take a look at now not most effective meticulously information the functions related to dynamic product control, user administration, and green evaluation moderation however additionally unravels the complicated interplay among these functionalities. The study provides a thorough knowledge of the way Bootstrap's responsive layout standards are interwoven into the cloth of the admin panel, making sure that operational efficiency isn't handiest a intention but a found out outcome. These responsive design concepts now not most effective enhance the visible enchantment but additionally empower administrators with a continuing and adaptable interface, fostering most desirable selection-making. In illuminating the interconnected dynamics of the MERN stack and Bootstrap inside the administrative realm, this research contributes to a nuanced comprehension of ways technology converges to raise the operational backbone of the inventory management device This exhaustive survey severely examines the intricate landscape of web-based stock control systems with a specific consciousness on the integration of cutting-edge web technologies the study delves into the scalability and versatility elements supplying valuable insights into the development of dynamic user interfaces that seamlessly adapt to the ever-evolving wishes of companies operating inside the inventory management area furthermore it explores how those dynamic interfaces foster a consumer-centric method empowering companies to efficiently navigate the demanding situations posed via fluctuating stock

demands and industry dynamics thereby ensuring sustained operational agility and adaptableness.

An in-depth exploration into the nuanced usage of MongoDB within the MERN stack for inventory control structures. The studies meticulously investigate its pivotal position in efficient stock monitoring and optimized purchase operations, presenting a nuanced information of ways MongoDB enhances data control in the tricky methods of stock structures. moreover, it delves into MongoDB's potential to address huge datasets and its robust indexing features, illuminating its importance in streamlining information retrieval and ensuring real-time insights for stock selection-makers. moreover, the research highlights MongoDB's schema-less design, bearing in mind dynamic and flexible data modelling, in the MERN stack, which proves to be instrumental in accommodating numerous stock attributes and evolving business requirements. by means of unraveling those intricacies, the study now not handiest underscores MongoDB's contribution to information performance but also well-known shows its adaptability as a foundational element in shaping the responsive and scalable nature of contemporary inventory control structures.

This complete examination delves into the multifaceted contributions of React in the expansive realm of net-based absolutely genuinely answers specializing in its pivotal feature in enhancing the consumer experience the look at elucidates how React contributes to intuitive navigation and seamless purchasing cart manage providing an intensive exploration of its profound effect within the tough tactics of stock systems moreover it explores reactjs as a flexible device for growing interactive and dynamic customer interfaces emphasizing its functionality to facilitate real-time updates and responsive format thereby ensuring a fluid and appealing purchaser adventure the research underscores React functionality to foster issue reusability streamlining improvement efforts and fostering a modular form internal stock control systems

A rigorous exploration of the multifaceted contributions of Node.js and its position inside the development of dynamic and responsive internet packages. The take a look at delves into the approaches Node.js complements decision-making methods thru the technology of insightful reviews, supplying an in-intensity exploration of its profound impact within the realm of stock control systems. moreover, it illuminates Node.js's performance in managing giant data hundreds, making sure fast and responsive records retrieval for real-time

decision-making. The research emphasizes how Node.js, with its non-blocking off I/O operations, extensively reduces processing delays, taking into consideration seamless get entry to crucial data and empowering stock managers with the agility required in dynamic operational eventualities.

This meticulous review seriously analyzes Bootstrap's profound impact on responsive design and operational efficiency inside web-based programs, emphasizing its position in crafting consumer-centric solutions. The study gives a complete exploration of Bootstrap's multifaceted contributions to the complicated strategies of stock structures, supplying nuanced insights into its profound impact inside this expansive domain. additionally, it underscores Bootstrap's versatility in expediting the development of responsive interfaces, permitting swift model to numerous display sizes and gadgets. The research sheds light on how Bootstrap's standardized components and styling options enhance the general person experience, fostering consistency and simplicity of navigation within the dynamic context of stock control structures.

Studies dedicated to unravelling the multifaceted benefits supplied by way of the combination of present-day net technology, exemplified with the aid of the MERN stack. The observe is going past surface-level evaluation, offering a complete understanding of ways these structures adapt to satisfy evolving organizational wishes in stock management, providing a nuanced exploration of their profound impact. It delves into the collaborative synergy of MongoDB, specific.js, React.js, and Node.js, elucidating how every factor contributes to a holistic and agile framework. The research navigates thru the scalability aspects of the MERN stack, emphasizing its innate potential to seamlessly accommodate growing facts volumes and person demands. additionally, it explores how this flexibility fosters organizational growth through making sure that inventory control systems can efficaciously evolve alongside dynamic enterprise requirements.

An exhaustive exploration delves deep into the complex security elements surrounding online transactions in net-based stock control systems. The study intricately examines the included fee gateways, imparting a whole fact of the multifaceted mechanisms hired to ensure at ease and dependable monetary transactions inside such complicated systems. It meticulously dissects the layers of security protocols, encryption methodologies, and real-time validation strategies embedded within those gateways, illuminating their essential

feature in fortifying the economic integrity of on-line transactions inside the dynamic landscape of stock management. moreover, the research extends its scrutiny to the evolving challenges in the cybersecurity region, emphasizing how the ones fee gateways constantly adapt to thwart growing threats and make sure the confidentiality, integrity, and availability of sensitive economic records. In elucidating the intricacies of charge gateway integration, this takes a look at now not exceptional underscores their important role in safeguarding transactions however additionally contributes to the broader discourse on improving the general cybersecurity posture of internet-based totally completely inventory manipulate structures.

This studies significantly evaluates the profound and multifaceted effect of entire internet-based totally without a doubt answers on preference-making techniques internal organizations. The test meticulously analyses how the mixing of the MERN stack and Bootstrap framework contributes to the overall performance of stock manipulate, providing nuanced insights into how those multifaceted technology informs strategic desire-making techniques within the expansive and complicated realm of stock systems. It sheds mild at the synergies a number of the MERN stack and Bootstrap, highlighting their collective feature in improving desire-making normal performance and strategic insights for powerful inventory control.

TECHNICAL COMPARISON

Language and Framework:

In the improvement of our e-commerce website, we adopted the modern MERN (MongoDB, Express.js, React, Node.js) stack due to its comprehensive capabilities. Utilizing MongoDB for flexible data storage, Express.js for robust server-side applications, React for dynamic front-end experiences, and Node.js for a unified development stack, we crafted a coherent and responsive platform. This selection not only streamlined our development process but also contributed to a more seamless and efficient user experience, surpassing the limitations associated with traditional technologies. Choosing conventional technologies such as PHP with Laravel or CodeIgniter could have presented challenges in achieving a similar level of responsiveness and interactivity. The reliance on server-side rendering might

have resulted in extended page loading times and a less dynamic user interface, ultimately impacting the overall user experience.

Database Management:

Implementing MongoDB in our e-commerce website gives a honest assessment and capacity to supplement product data conventional relational databases together with MySQL or PostgreSQL can gift challenges in handling unstructured and semi-structured e-commerce statistics mongodbs nosql version permits us to fast adapt to changes in statistics merchandise and patron alternatives selecting a conventional relational database for an e-exchange web site calls for a greater rigid database making it hard to transport between merchandise and categories.

Real-Time Interactivity:

Imposing web sockets and technology like graphql in our men stack drastically superior real-time interactivity on our e-commerce platform customers can now revel in stay updates for inventory modifications pricing updates and interactive factors seamlessly in evaluation relying on ajax for constrained actual-time interactivity as in traditional technologies could have limited our capability to supply a more dynamic and tasty purchasing enjoy the person could have skilled delays and much less responsive interactions impacting consumer pleasure

Front-End Development:

The adoption of React.js for our e-commerce the front-give up delivered about a paradigm shift in how we control and display product facts. The thing-based totally architecture now not best advanced code modularity and maintainability but additionally allowed for the introduction of a particularly interactive and visually attractive user interface.

If we had stuck with traditional front-quit development using jQuery, we might have encountered challenges in handling the complexity of the codebase and imparting a present day, responsive layout. the dearth of a element-based totally structure may want to have led to less scalable and maintainable code.

Responsive Design:

Bootstrap and CSS framework play an crucial position in reaching a robust design of our e-commerce web page and when we select the traditional CSS trouble the presets and widgets supplied with the template will assist you to use multiple widgets create a stable

and bendy shape location it takes a number of work and time to complete the response within the interface this consequences in inconsistencies in equipment and display sizes.

Security Measures:

In response to changing safety threats, we use HTTPS as trendy safety on our e-commerce internet site, along with extra strategies consisting of JSON net Tokens (JWT) and OAuth 2.0, to ensure security and patron pride. state-of-the-art technology substantially improves the overall protection of our platform. As inside the beyond, when counting on preliminary SSL encryption, our e-commerce websites might be extra at risk of threats. protection functions now offer greater protection in opposition to capacity vulnerabilities.

Cloud Computing:

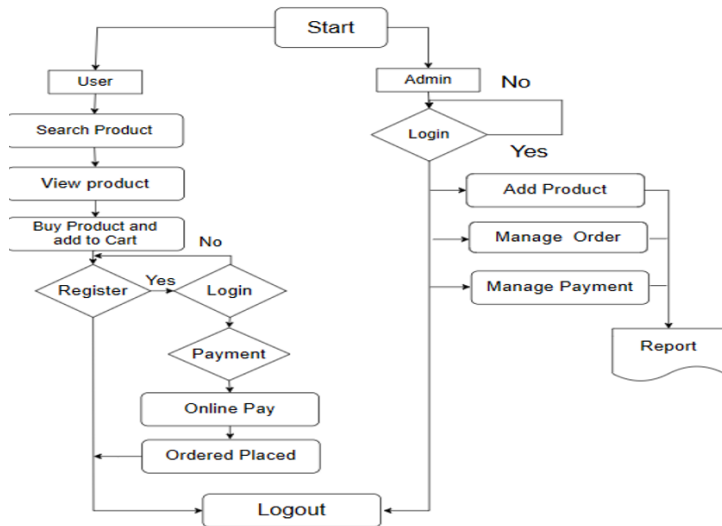

Selecting a cloud device along with aws azure or google cloud to host our e-commerce website lets in us to gain from a fee-powerful answer the strength furnished by using cloud computing enables manipulate green offerings permitting our platform to be tailored to users distinctive desires scalability is the maximum critical aspect if we pick conventional nearby web hosting or traditional server configuration horizontal scaling entities will be less dependable and can motive average performance bottlenecks on height site visitors

Development Workflow:

Using agile methodologies, DevOps practices, and CI/CD pipelines made it easy to improve the overall performance of our e-trade website. This streamlined technique encourages quicker iterations, increases collaboration within the development team, and creates greater impact. If we observe the traditional waterfall design model, consistent growth can inhibit our capacity to quickly adapt to the needs of the business. The agility provided by modern development is essential to remain competitive in a dynamic e-commerce environment.

SYSTEM ARCHITECTURE

The contemporary customer journey for acquiring products online is a streamlined and efficient process. It begins with product discovery, typically facilitated by intuitive search functions and categorized browsing experiences. Customers actively seek desired items using keywords or explore relevant categories presented by the online retailer. Once a potential product is identified, a thorough product evaluation phase commences.

This involves meticulously reviewing detailed descriptions, scrutinizing high-resolution images, and carefully assessing specifications to ensure the product aligns with their specific needs and expectations.

Having meticulously evaluated the product and deemed it suitable, customers seamlessly add it to their virtual shopping cart, acting as a temporary holding space for their chosen items. When ready to finalize the purchase, they navigate towards the checkout section. Here, established customers can leverage the convenience of logging in with existing credentials, while new customers can efficiently create accounts for future purchases. Regardless of the chosen path, accurate delivery information must be provided to ensure the seamless and timely arrival of the product.

The final and crucial step involves secure payment processing. Depending on the platform, customers can choose their preferred method from a selection of secure options, such as credit cards, debit cards, or alternative payment channels offered by the retailer. Upon successful payment confirmation, the online retailer transmits an order confirmation to the customer, outlining the estimated delivery timeframe and providing a unique tracking number for real-time shipment monitoring. With this, the online acquisition journey concludes, leaving the customer to eagerly anticipate the arrival of their coveted purchase.

RESULT

The implementation of the MERN stack and Bootstrap framework in developing our e-commerce website has yielded noteworthy effects. The system effectively manages stock,

ensuring actual-time updates and efficient monitoring through MongoDB integration. A person-centric approach and intuitive navigation make a contribution to an more advantageous shopping for enjoy, with streamlined buying facilitated with the aid of integrated charge gateways ensuring cozy on line transactions.

The executive panel, powered via the MERN stack, empowers directors with robust product control, user control, and review moderation abilities. The responsive layout, courtesy of Bootstrap, guarantees a consistent and most excellent person experience throughout devices, promoting accessibility and usefulness. Automation of stock tasks complements operational performance, and the gadget generates insightful reports for informed selection-making.

Scalability and versatility inherent within the MERN stack architecture allow the machine to adapt to changing necessities and accommodate growth. In end, this task effectively leverages cutting-edge technology, demonstrating a sturdy, person-friendly, and efficient e-trade website with the ability for similarly enhancements in the on-line retail landscape.
